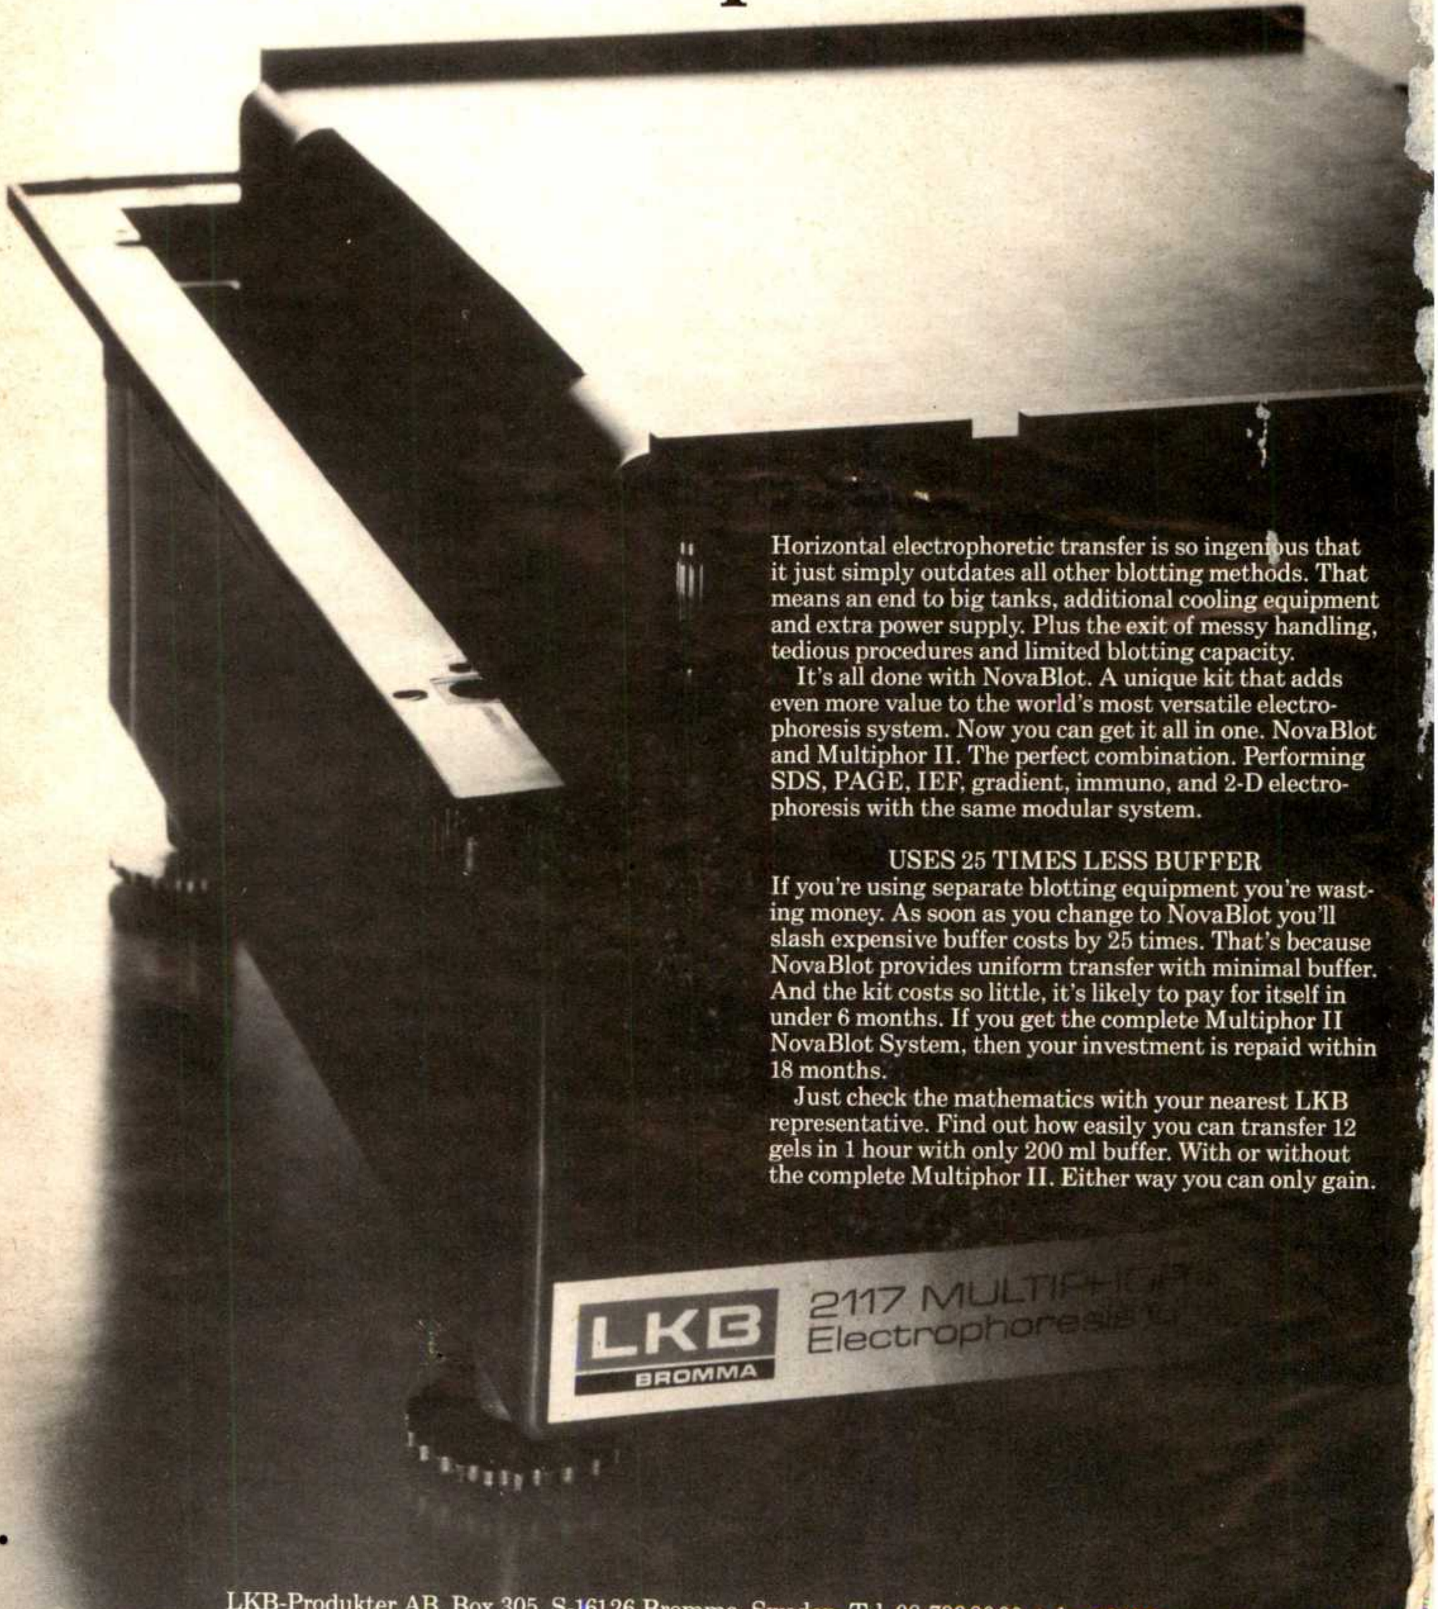
GIANT SUBTIDAL STROMATOLITES

315

Entered
29.1.87

Now Multiphor II gives you horizontal electrophoretic transfer



Horizontal electrophoretic transfer is so ingenious that it just simply outdates all other blotting methods. That means an end to big tanks, additional cooling equipment and extra power supply. Plus the exit of messy handling, tedious procedures and limited blotting capacity.

It's all done with NovaBlot. A unique kit that adds even more value to the world's most versatile electrophoresis system. Now you can get it all in one. NovaBlot and Multiphor II. The perfect combination. Performing SDS, PAGE, IEF, gradient, immuno, and 2-D electrophoresis with the same modular system.

USES 25 TIMES LESS BUFFER

If you're using separate blotting equipment you're wasting money. As soon as you change to NovaBlot you'll slash expensive buffer costs by 25 times. That's because NovaBlot provides uniform transfer with minimal buffer. And the kit costs so little, it's likely to pay for itself in under 6 months. If you get the complete Multiphor II NovaBlot System, then your investment is repaid within 18 months.

Just check the mathematics with your nearest LKB representative. Find out how easily you can transfer 12 gels in 1 hour with only 200 ml buffer. With or without the complete Multiphor II. Either way you can only gain.

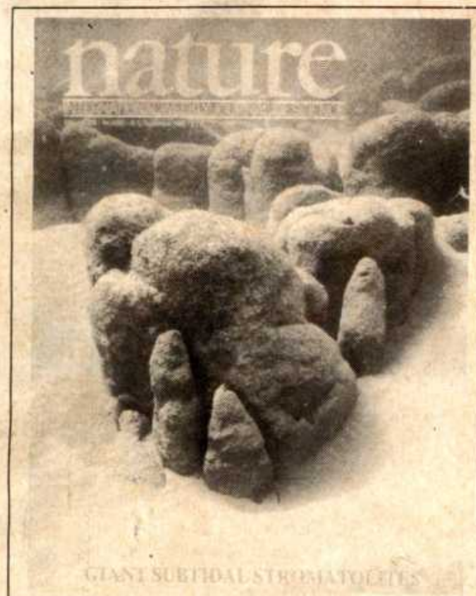
NATURE VOL. 324 6 NOVEMBER 1986



Underwater view of giant stromatolites (up to 2.5 metres high forming at a depth of 7 metres in a tidal channel in the Bahamas. These are the largest modern examples yet discovered, and their occurrence in water of normal salinity sheds new light on the environmental significance of their ancient counterparts, which flourished in the Precambrian, more than 2,500 million years ago (see p.55).

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Journals Ltd and includes the Annual Index (mailed in February). Annual subscription for USA and Canada US $250. USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 1501, Neptune, NJ 07753, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY 10012 and additional mailing offices. Authorization to photocopy material for internal or personal use, or internal or personal use of specific clients, is granted by *Nature* to libraries and others registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided the base fee of $1.00 a copy plus $0.10 a page is paid directly to CCC, 21 Congress Street, Salem, Massachusetts 01970, USA. Identification code for *Nature*: 0028-0836/86 $1.00 + $0.10. US Postmaster send address changes to: *Nature*, 65 Bleecker Street, New York, NY 10012. Published in Japan by Macmillan Shuppan K.K., Eikow Building, 1-10-9 Hongo, Bunkyo-ku, Tokyo, Japan. © 1986 Macmillan Journals Ltd.

CUSTOM SYNTHETIZED DNA AT EXTREMELY LOW PRICES

Prices (USD) per purified oligomer up to the length of 35:

	Basic fee	Per base
0.05 A260 units (~ 1.5 μg)	85	5.50
0.2 A260 units (~ 6 μg)	125	7.50
1 A260 unit (~30 μg)	170	10.00

SPECIAL OFFER: FREE OLIGONUCLEOTIDES

FOR EVERY FIVE OLIGOMERS YOU BUY
YOU GET ONE ADDITIONAL OLIGOMER FOR FREE

WHY BUY MORE THAN YOU ACTUALLY NEED?

1 μg OF OLIGONUCLEOTIDE IS SUFFICIENT FOR:

- 10 oligonucleotide-directed mutagenisis experiments.
- 100 hybridization and gene synthesis experiments.
- 1000 dideoxy sequencing experiments.
- More than 1000 cloning experiments.

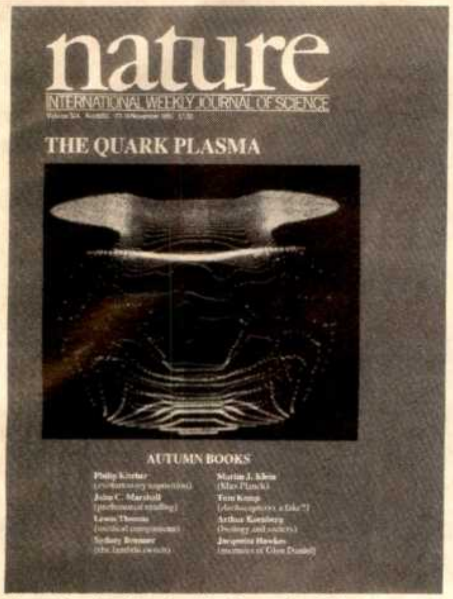
nature

NATURE VOL. 324 13 NOVEMBER 1986



Very shortly after the Big Bang, the Universe was a plasma of three quarks. Quantum chromodynamics has provided first predictions for such quark matter, and an experimental quark plasma search is starting this autumn using energetic nuclear collisions to produce bubbles of 'primordial matter'. The cover shows a computer simulation of such a collision between oxygen and uranium nuclei. See page 116.

For a quarter of a century, researchers looking at cell division have measured thymidine kinase (TK) activity indirectly by measuring the incorporation of radioactive thymidine. Now you can measure TK activity directly in serum using the Prolifigen® Thymidine Kinase Radioenzyme Assay (TK-REA). Certain types of malignant disease are characterised by a particularly rapid cell proliferation; increased proliferation means an increased level of TK. Serum TK measurements have a proven clinical use for prognosis and follow-up in such diseases, particularly lymphomas, leukaemias and small-cell lung cancer. Contact Sangtec today and measure TK the easy way.

TK-REA is the way to measure Thymidine Kinase.

What's the difference between here,
and here?
ZURICH

Nothing…

In short, you'll find the same excellent standards of service and efficiency down on the ground at Zurich and Geneva airports as you're used to on a Swissair flight at 39,000 feet.

There are always times when you can't fly direct to your long-haul destination and a transit stop can be a daunting prospect.

At Zurich and Geneva you'll experience first rate amenities and an organisation that ensures that everything runs like clockwork. So that your short time on the ground becomes a pleasure, not a pain.

Connecting flights will take you to over 100 destinations worldwide, on which you can experience the level of service that's won us Business Traveller Magazine's Best Airline award every year since it started in 1980.

Fly Swissair. We make all the right connections.

PHASE-DEPENDENT MACH BANDS
IMMUNOLOGY/MONOCLONALS
product review

Two-dimensional Mach bands at four different scales. The horizontal and vertical cross-sections of the luminance distribution are triangular, but give rise to illusory star patterns. A theory of feature detection based on phase congruence (p.250) explains the appearance of the stars and why the pattern outline pinches in at smaller scales.

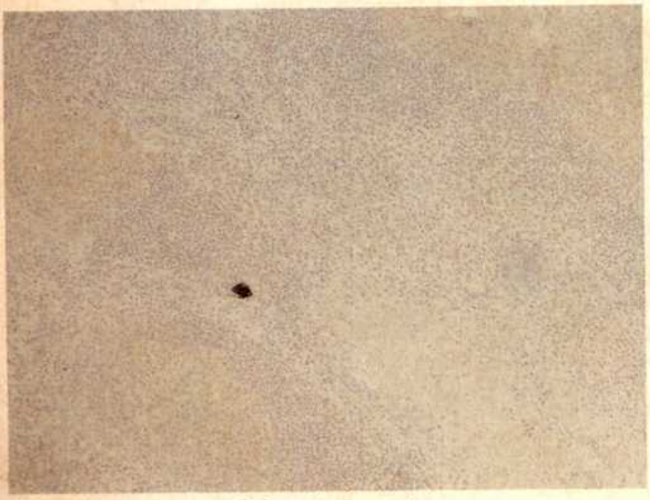
Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Journals Ltd and includes the Annual Index (mailed in February). Annual subscription for USA and Canada US $250. USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 1501, Neptune, NJ 07753, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY 10012 and additional mailing offices. Authorization to photocopy material for internal or personal use, or internal or personal use of specific clients, is granted by *Nature* to libraries and others registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided the base fee of $1.00 a copy plus $0.10 a page is paid directly to CCC, 21 Congress Street, Salem, Massachusetts 01970, USA. Identification code for *Nature*: 0028-0836/86 $1.00 + $0.10. US Postmaster send address changes to: *Nature*, 65 Bleecker Street, New York, NY 10012. Published in Japan by Macmillan Shuppan K.K., Eikow Building, 1-10-9 Hongo, Bunkyo-ku, Tokyo, Japan. © 1986 Macmillan Journals Ltd.

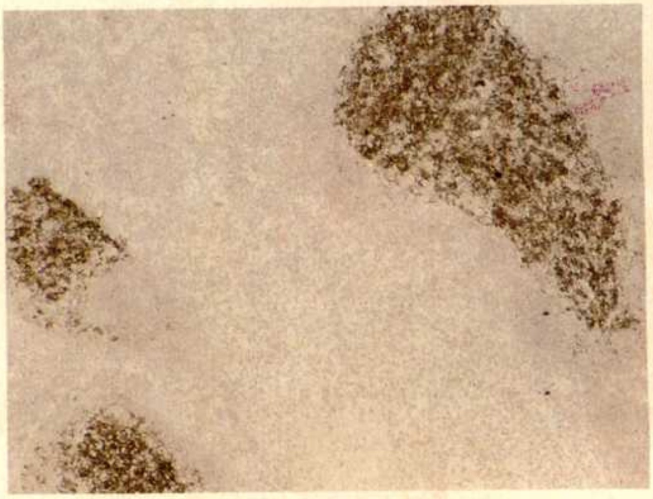
Enhance your DAB

with our DAB silver enhancement kit

A method for amplifying small amounts of 3,3′-diaminobenzidine precipitated on cells or tissues by immunoperoxidase.*



Before enhancement



After enhancement

- Immunoperoxidase staining of rare antigens can now be visualized.
- Concentrations of scarce or expensive monoclonal antibodies can be reduced without loss of sensitivity.
- Incubation times can be reduced.
- Improved contrast of immunoperoxidase-DAB photomicrographs.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

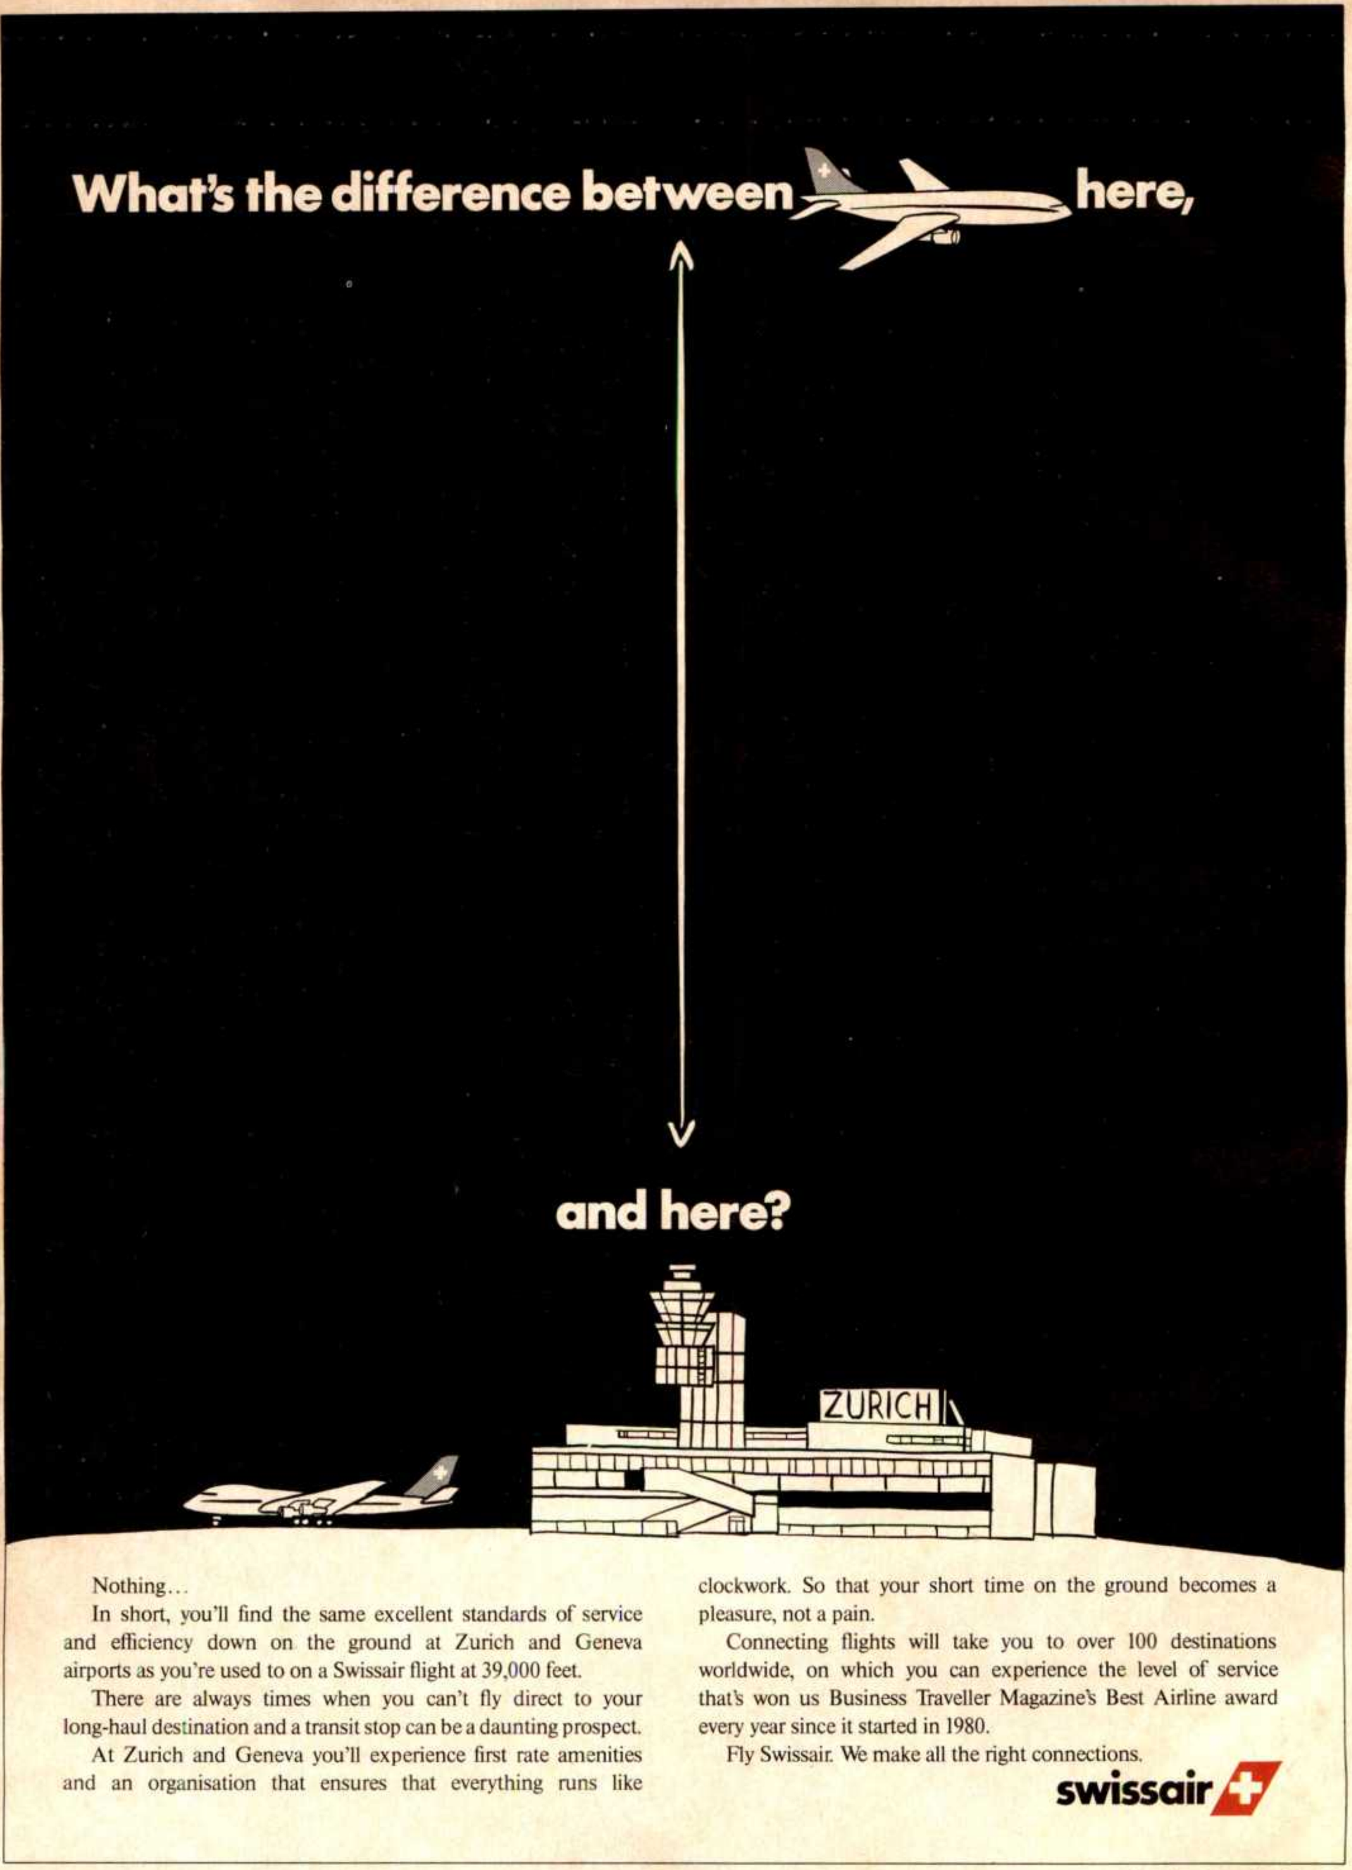
Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Important: Manuscripts of proofs sent by air courier should be declared as "manuscripts" and "value $5" to prevent the imposition of Customs duty and Value Added Tax in the United Kingdom.



What's the difference between here,
and here?
ZURICH

Nothing…

In short, you'll find the same excellent standards of service and efficiency down on the ground at Zurich and Geneva airports as you're used to on a Swissair flight at 39,000 feet.

There are always times when you can't fly direct to your long-haul destination and a transit stop can be a daunting prospect.

At Zurich and Geneva you'll experience first rate amenities and an organisation that ensures that everything runs like clockwork. So that your short time on the ground becomes a pleasure, not a pain.

Connecting flights will take you to over 100 destinations worldwide, on which you can experience the level of service that's won us Business Traveller Magazine's Best Airline award every year since it started in 1980.

Fly Swissair. We make all the right connections.

For a quarter of a century, researchers looking at cell division have measured thymidine kinase (TK) activity indirectly by measuring the incorporation of radioactive thymidine. Now you can measure TK activity directly in serum using the Prolifigen® Thymidine Kinase Radioenzyme Assay (TK-REA). Certain types of malignant disease are characterised by a particularly rapid cell proliferation; increased proliferation means an increased level of TK. Serum TK measurements have a proven clinical use for prognosis and follow-up in such diseases, particularly lymphomas, leukaemias and small-cell lung cancer. Contact Sangtec today and measure TK the easy way.

TK-REA is the way to measure Thymidine Kinase.

SCIENCE IN IBERIA

Spain and Portugal have recently emerged from social and political upheavals: how has the practice of science been affected?

In this special issue (27.11.86) Nature publishes a survey by Alun Anderson of new developments in both countries, in which he comments on key issues affecting Iberian scientists:

✻ What will Spain's new "law of science" achieve?

✻ Can Iberia reach the technological level needed to compete in the European Community?

✻ What have Iberia's researchers gained from their first decade of democracy?

Ordering information and prices as for back issues below.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Important: Manuscripts of proofs sent by air courier should be declared as "manuscripts" and "value $5" to prevent the imposition of Customs duty and Value Added Tax in the United Kingdom.

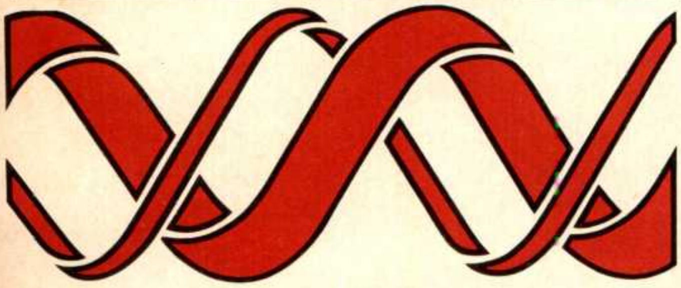
Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

ANNOUNCIN

BIO/TECHNOLOGY NEW

JANUARY 2

• GENE REGULATION • RECEPTO



CONFERENCE PROGRAM

Plenary Address
George Poste
Smith Kline & French Research Laboratories

DAY 1 • Regulation of Gene Expression

Satellite Phage P4
Richard Calendar, University of California, Berkeley

Soybean Seed Protein in Transformed Plants
Robert Goldberg, University of California, Los Angeles

The Immunoglobulin Gene Superfamily
Leroy Hood, California Institute of Technology

Transcriptional Activation
Martin Rosenberg, Smith Kline & French Research Laboratories

Organ-specific Gene Expression in Chimeric Plants
Marc Van Montagu, Rijsuniversiteit Gent

Alpha Interferon
Charles Weissmann, University of Zurich

DAY 2 • Receptor Biology: Towards New Pharmaceuticals

Receptor Regulation and Hypercholesterolemia
Michael Brown, University of Texas Southwest Medical School

Antireceptor Antibodies
Mark Greene, University of Pennsylvania

Epidermal Growth Factor Receptor Gene
Ira Pastan, National Cancer Institute

The T-Cell Receptor
Susumu Tonegawa, Massachusetts Institute of Technology

Growth Factor Receptor Tyrosine Kinases
Axel Ullrich, Genentech, Inc.

The Interleukin-2 Receptor
Thomas Waldmann, National Cancer Institute

DAY 3 • Redesigning Proteins

After the Cloning is Over
Charles Craik, University of California, San Francisco

A Biophysical Approach to Protein Secretion
Lila Gierasch, University of Delaware

Recovering and Refolding Active Oligomeric Proteins
Rainer Jaenicke, Universitat Regensburg

Genetic Indentification of Protein Folding Pathways
Jonathan King, Massachusetts Institute of Technology

Modifying Enzymatic Activity and Stability
Gregory Petsko, Massachusetts Institute of Technology

Disulfide Bonds and Protein Stability
Ronald Wetzel, Genentech, Inc.

The second Bio/Technology Conference will tackle the many scientific issues in commercial protein production. Understanding receptor biology is essential to developing everything from vaccines to cancer therapeutics to heart drugs. Increasing dependence on commercial production in mammalian cells makes it critically important to understand the development of eukaryotic gene regulation. And recovering and refolding complex proteins into bioactive forms is the key step in making usable products.

Next January in New Orleans, leading scientists from around the world will come together to discuss their most recent research, and to explore three key issues essential to the rapid development of biotechnology.

- **Gene regulation and expression**
- **Receptor genetics and function**
- **Structure/function relationships in proteins.**

You will be updated on work that is leading to new pharmaceuticals. We'll discuss the protein folding problem. Rearrangement of the DNA template. Details of the molecular structure and function of receptors such as ligand processing and drug effects. Transactivation of viral and mammalian genes.

This conference is an exceptional opportunity to hear from an outstanding group of speakers, and to exchange ideas and information with them — as well as with other conference delegates.

New Products on View

In conjunction with the conference, there will be an exhibition of the latest scientific products and services offered by leading research labs, pharmaceutical firms, publishers and many others. Representatives will be on hand to discuss their products and to answer your questions.

Submit Your Work for Poster Sessions

There will be a limited number of opportunities for poster presentations, and we invite scientists who are interested to submit abstracts of relevant work for consideration. Mail abstracts to:

Research Editor
Bio/Technology
65 Bleecker Street
New York, NY 10012

Registration will be limited, so be sure to register early.
BIO/TECHNOLOGY subscribers save an additional $50.

nature

The huge hydrogen cloud surrounding the nucleus of comet Halley, as seen in the ultraviolet (Lyman-α). The direction of the Sun is to the bottom of the image. The outermost yellow ring is about 10 million kilometres across its long axis. The false colour coding distinguishes regions of different brightness and is multivalued to enhance contrast. The image was taken from a sounding rocket on 13 March. Studies of Halley from rocket, aircraft and satellite are reported on pages 433–444.

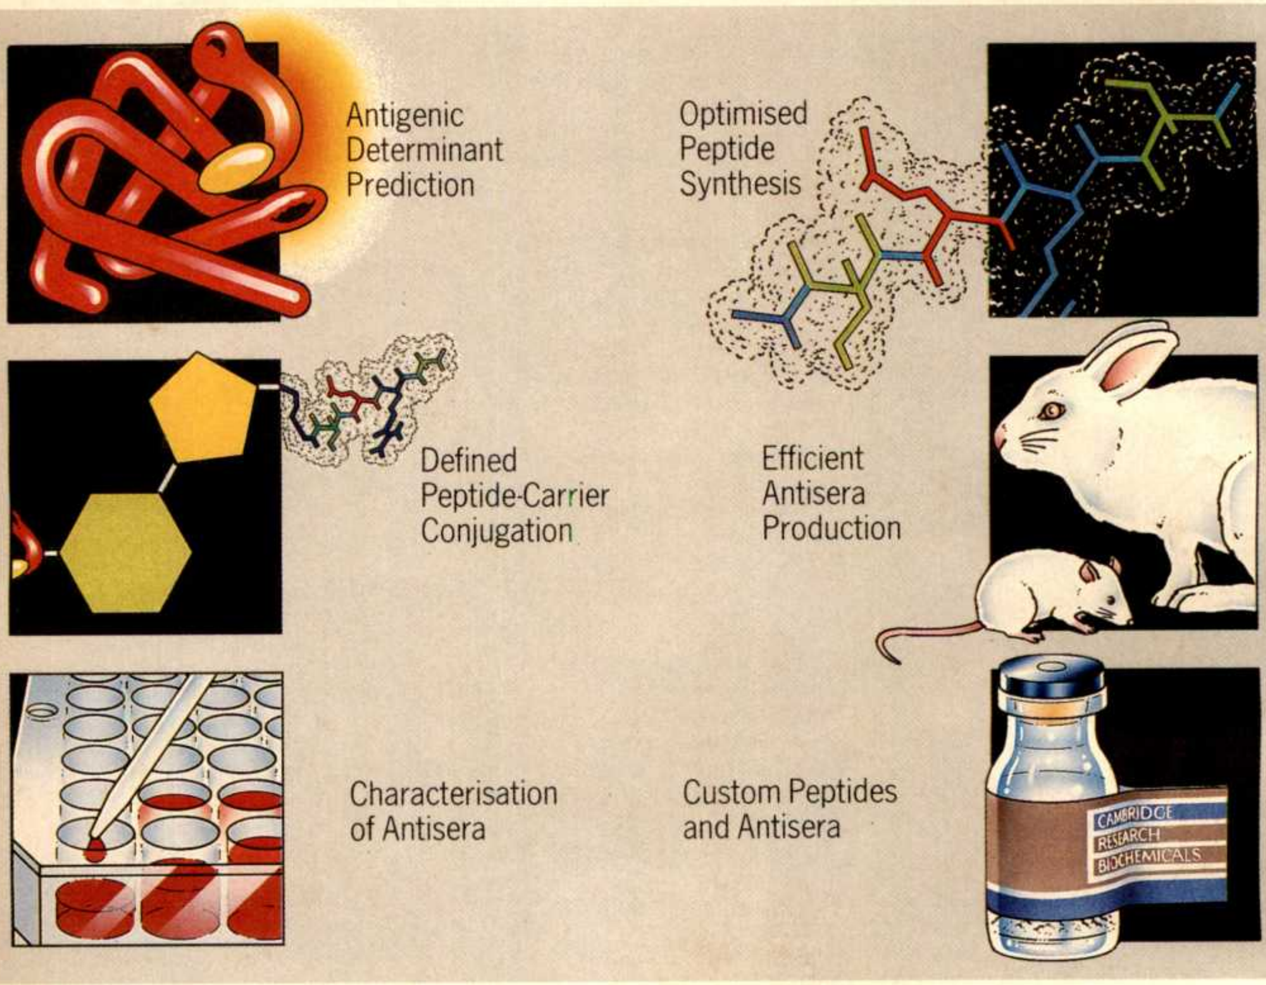
Custom Peptides and Antisera...



...the Complete Service.

An expanded custom service for the rapid production of synthetic peptides and antipeptide antibodies is now available from the specialists in peptide research, Cambridge Research Biochemicals.

Developed to meet all your project needs, this confidential service includes hydropathic analysis to identify potential antigenic determinants and the efficient Fmoc-polyamide synthesis of selected peptides which are subsequently fully characterised.

Employing defined peptide-carrier conjugation and optimised immunisation protocols together with the assay of sera for anti*peptide* activity, the Cambridge Research Biochemicals custom service provides you with a unique product of the required pre-determined specificity.

Contact Dr Paul Sheppard, Contract Research Director, now for further details of this exciting new service or simply send for a free copy of the new 'Synthetic Peptides For Molecular Biology' brochure and discover how we produce the best at Cambridge.

SCIENCE IN IBERIA

Spain and Portugal have recently emerged from social and political upheavals: how has the practice of science been affected?

In this special issue (27.11.86) Nature publishes a survey by Alun Anderson of new developments in both countries, in which he comments on key issues affecting Iberian scientists:

- What will Spain's new "law of science" achieve?
- Can Iberia reach the technological level needed to compete in the European Community?
- What have Iberia's researchers gained from their first decade of democracy?

BIOSYSTEMS UPDATE

For People who make Peptides

Here are five reasons why.

1 It's the Truly Efficient Way to Make Peptides

The Model 430A Peptide Synthesizer doesn't waste time, amino acids, or reagents. It consistently produces high yields of quality peptide which reduces post-synthesis purification and analysis significantly. You get more peptide for your effort *and* for your dollar.

2 It's More Flexible, Easier to Operate

The 430A meets the needs of every user whether new to peptide synthesis or very experienced. Software is written in plain English using familiar terminology. All control is implemented by simply touching the screen. Standard synthesis cycles and functions can be selected or new ones designed quickly and easily.

3 Its Chemistry is Proven and Unique

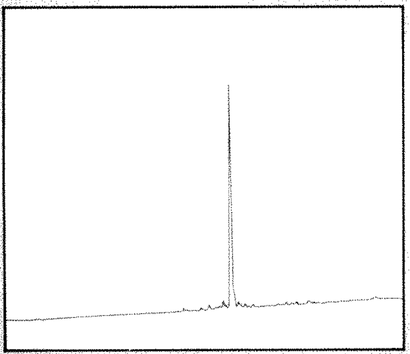
High stepwise yields, high purity and reproducibility are routine. Each step of the chemistry is specific to the requirements of the various amino acids. Coupling failures are eliminated or greatly reduced resulting in fewer double couplings. Both *t*-Boc and FMOC chemistries can be accommodated.

4 It Produces Superb Short Peptides

Step Yield (% Coupled) Standard ABI *t*-Boc cycles, version 1.0

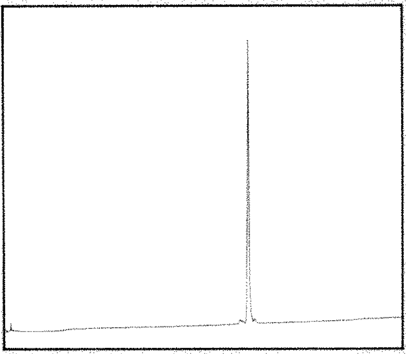
PEPTIDE SEQUENCE	LEU	HIS	PHE	PRO	HIS	ILE	TYR	VAL	ARG	ASP	AVG. STP. YIELD %
Ninhydrin Analysis	•	96.7	99.7	99.7	†99.6	98.9	99.5	98.3	99.5	99.4	**99.0**
Preview Sequence Analysis	•	•	•	99.5	99.2	94.9	96.6	96.5	97.1	97.9	**97.4**
RESIDUE NUMBER	10	9	8	7	6	5	4	3	2	1	

†Ninhydrin values for amino acids coupled to proline are not quantitative.



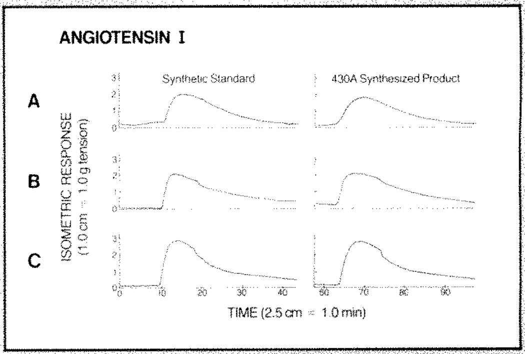
Angiotensin I, Crude

mobile phase	0.1% TFA/CH_3CN
gradient	0 to 60% in 60 minutes
flow rate	1.0 mL/min
detector	216 nm
column	Brownlee, C-8, 300Å, 10μm 4.6 mm x 250 mm



Angiotensin I, HPLC Purified

mobile phase	0.1% TFA/CH_3CN
gradient	0 to ≥ 60% in 60 minutes
flow rate	1.0 mL/min
detector	216 nm
column	Brownlee, C-8, 300Å, 10μm 4.6 mm x 250 mm



Panels A, B and C are isometric responses of two different Ile^5-Angiotensin I—a synthetic standard and the 430A-produced, purified peptide—on three separate rabbit aortic strips. The responses produced by the Applied Biosystems Ile^5-Angiotensin I were not significantly different than those of the standard. Sample concentrations were: in panel A, 564 ng/mL; in panels B and C, 500 ng/mL.

These response data were furnished by Drs. M. C. Khosla and A. Husein of the Cleveland Clinic Foundation.

nature

Reflected light micrograph of a section of rock salt from the Asse Mine (Germany). Rock salt is important as a material for use in radioactive waste depositories and for its association with oil traps. The effect of water on the low-stress rheology of rock salt is discussed on pages 554–557 of this issue and also in a News and Views article on page 515.

GUIDE TO AUTHORS

Authors should be aware of the diversity of ***Nature***'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in ***Nature***. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Important: Manuscripts or proofs sent by air courier should be declared as "manuscripts" and "value $5" to prevent the imposition of Customs duty and Value Added Tax in the United Kingdom.

GENECLEAN™

WHY SHOULD IT BE SO TIME-CONSUMING OR DIFFICULT OR EXPENSIVE TO DESALT OR PURIFY DNA SOLUTIONS, OR REMOVE DNA FROM AGAROSE?

IT SHOULDN'T . . .

AND NOW IT ISN'T. BIO 101 INTRODUCES **GENECLEAN™** A "QUICKIT" THAT ENABLES THE MOLECULAR BIOLOGIST TO:

- ☑ **REMOVE AND PURIFY DNA FROM AGAROSE GELS FAST** ... 20 minutes from Gel-Band to purified DNA in water or TE.
- ☑ **REMOVE UNREACTED TRACER-NUCLEOTIDES FROM LABELING REACTIONS and/or DESALT AND CONCENTRATE DNA SOLUTIONS, EVEN THOSE IN PHOSPHATE, FAST** ... 15 minutes without columns, alcohol precipitations or organic extractions.
- ☑ **ELIMINATE ENZYME-INHIBITING IMPURITIES FROM DNA SOLUTIONS FAST** ... 15 minutes to remove protein, small RNA and other enzyme-inhibiting impurities from DNA solutions. For example, remove RNA and protein from crude mini-plasmid cleared-lysates without protease, RNase, organic extractions or alcohol precipitations.
- ☑ **ELIMINATE NEED FOR ALCOHOL PRECIPITATION OF DNA** ... 15 minute **GENECLEAN** process serves the same purpose as alcohol precipitation of DNA, often with increased recovery.
- ☑ **REMOVE TRACES OF ORGANIC SOLVENTS FAST** ... 15 minutes to remove residual enzyme-inhibiting phenol, chloroform or ether from extracted solutions of DNA.
- ☑ **"QUICKCLONE" FROM HIGH MELTING-POINT AGAROSE GELS.**

BIO 101

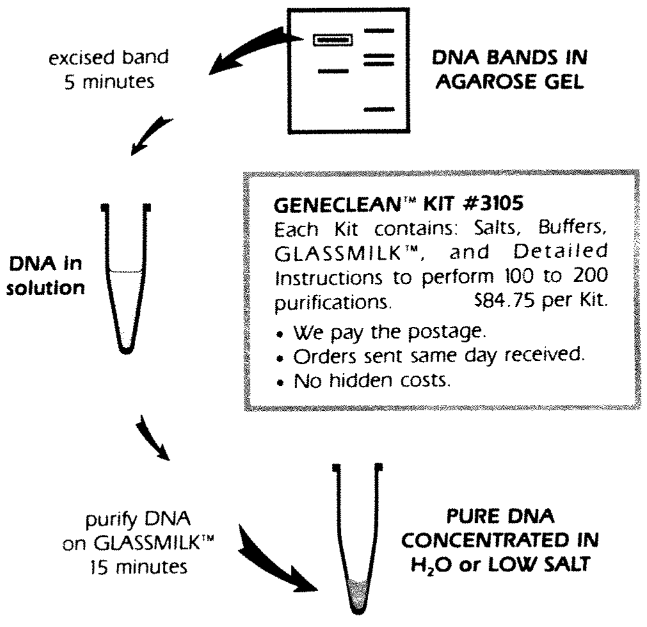
"DURING THE COURSE OF DOING RESEARCH, CHECK WITH BIO 101 ... WE HAVE YOUR TIME IN MIND."

MAILING ADDRESS:
BIO 101, INC., P.O. BOX 2284, LA JOLLA, CALIFORNIA 92038-2284

LOCATION:
4206-H SORRENTO VALLEY BLVD., SAN DIEGO, CA 92121

DNA TREATED WITH GENECLEAN IS A READY SUBSTRATE FOR MODIFYING ENZYMES ... without further manipulation.

GENECLEAN™ provides excellent recovery of single and double stranded DNA and it is not inhibited by SDS, organic solvents or protein.



excised band
5 minutes
DNA BANDS IN AGAROSE GEL
DNA in solution
purify DNA on GLASSMILK™ 15 minutes
PURE DNA CONCENTRATED IN H₂O or LOW SALT

GENECLEAN™ KIT #3105
Each Kit contains: Salts, Buffers, GLASSMILK™, and Detailed Instructions to perform 100 to 200 purifications. $84.75 per Kit.

- We pay the postage.
- Orders sent same day received.
- No hidden costs.

BIO 101 WANTS YOU TO BE PLEASED WITH ITS PRODUCTS. If you are not satisfied with the performance of **GENECLEAN™** return it within 30 days and we will refund your payment immediately.

To order **GENECLEAN™** Kit or for further information:

[1] Transforming growth factor type beta isolated from human platelets (hTGFβ) or from porcine platelets (pTGFβ1) is sequentially (first 50 a.a.) and biologically identical. Both give an ED$_{50}$ of 0.1-0.4 ng on NRK (49F) cells when assayed as per Assoian *et al* JBC *258*, 7155, 1983, and 0.8-1.0 ng/ml on AKR (2B) after Tucker *et al* CAN RES *43*, p1581, 1983.

[2] pTGFβ2 is a structurally distinct second form of TGFβ (sequence homology 70% in the first 50 a.a. to hTGFβ/pTGFβ1). When assayed as above, it gives the same ED$_{50}$s on NRK and AKR cells. However, some cell lines can distinguish between pTGFβ2 versus pTGFβ1/hTGFβ.

[3] Human platelet derived growth factor h(PDGF) is assayed on Balb/c-3T3 and NIH-3T3 cells for H^3-thymidine incorporation as per Raines and Ross, Meth. in Enz. *109*, p749.

[4] Porcine PDGF is structurally very different from hPDGF (i.e. differs in M.W., subunit composition, N-terminus), and is biologically less active in thymidine incorporation assays.

[5] Both the acidic and basic forms of bovine fibroblast growth factor are isolated from brain and assayed for H^3-thymidine incorporation on NR6-3T3 cells after Gospodarowicz, *et al* JBC, *253*, p3736, 1978.

SCIENCE IN IBERIA

Spain and Portugal have recently emerged from social and political upheavals: how has the practice of science been affected?

In this special issue (27 11 86) Nature publishes a survey by Alun Anderson of new developments in both countries, in which he comments on key issues affecting Iberian scientists

- ✻ What will Spain's new "law of science" achieve?
- ✻ Can Iberia reach the technological level needed to compete in the European Community?
- ✻ What have Iberia's researchers gained from their first decade of democracy?

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature* s readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable)

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding The text should not exceed 3 000 words and six displayed items (figures plus tables) The article should include an italic heading of about 50 words

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items The first paragraph (not exceeding 150 words) should say what the letter is about why the study it reports was undertaken and what the conclusions are

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature* The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted

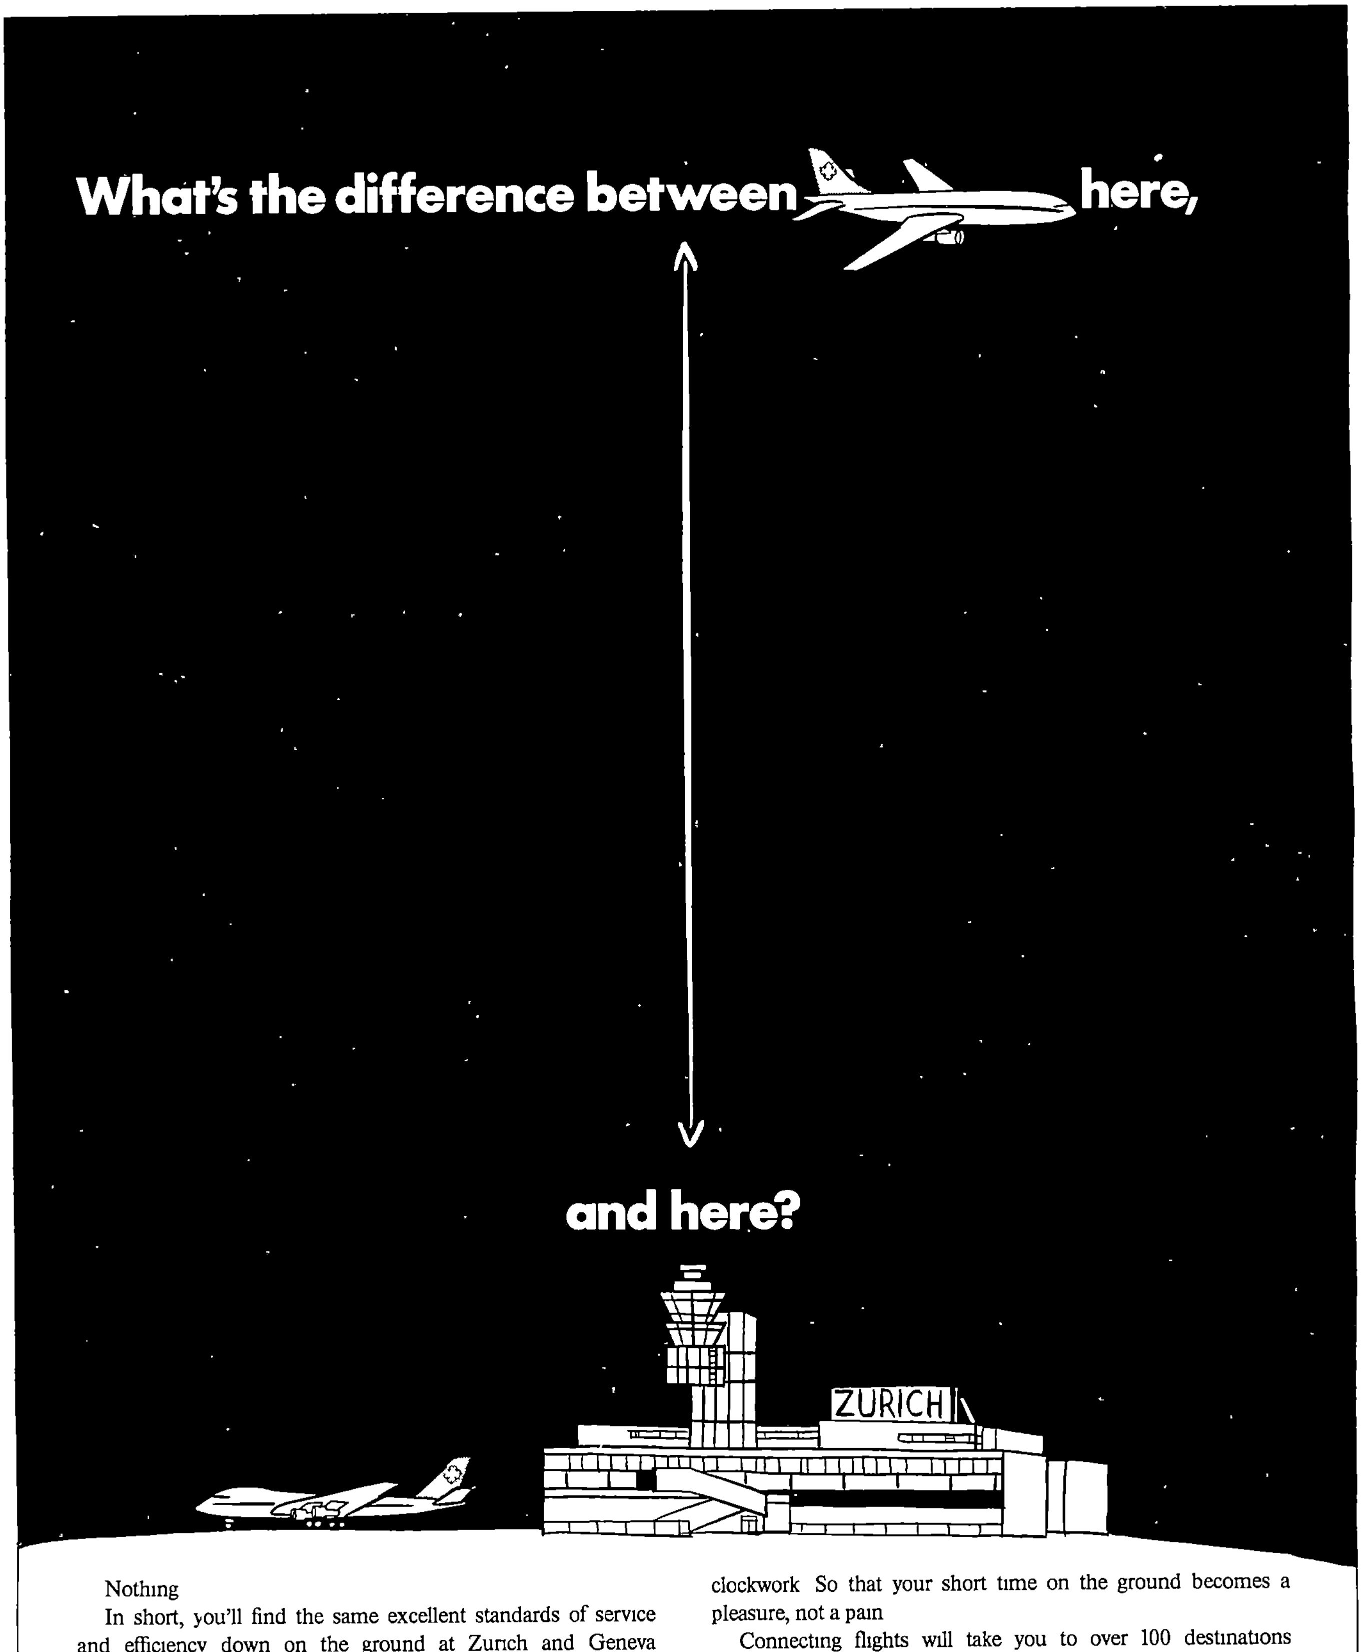
Manuscripts may be submitted either to London or Washington Manuscripts should be typed (double spacing) on one side of the paper only Four copies are required, each accompanied by copies of lettered artwork No title should exceed 80 characters in length Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963 65) The first and last page numbers of each reference should be cited Reference to books should clearly indicate the publisher and the date and place of publication Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text

Each piece of artwork should be clearly marked with the author s name and the figure number Original artwork should be unlettered Suggestions for cover illustrations are welcome Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published

Important Manuscripts of proofs sent by air courier should be declared as manuscripts' and value $5 to prevent the imposition of Customs duty and Value Added Tax in the United Kingdom

Requests for permission to reproduce material from Nature *should be accompanied by a self addressed (and in the case of the United Kingdom and United States stamped) envelope*



What's the difference between here,
and here?
ZURICH

Nothing

In short, you'll find the same excellent standards of service and efficiency down on the ground at Zurich and Geneva airports as you're used to on a Swissair flight at 39,000 feet

There are always times when you can't fly direct to your long-haul destination and a transit stop can be a daunting prospect

At Zurich and Geneva you'll experience first rate amenities and an organisation that ensures that everything runs like clockwork So that your short time on the ground becomes a pleasure, not a pain

Connecting flights will take you to over 100 destinations worldwide, on which you can experience the level of service that's won us Business Traveller Magazine's Best Airline award every year since it started in 1980

Fly Swissair We make all the right connections

NATURE VOL 324 6 NOVEMBER 1986

What must be done about AIDS

Governments can no longer hope that AIDS will simply go away Time could yet show that AIDS is as great a threat as nuclear war. And the time has come to act But how?

THERE are two extreme views about the occurrence of AIDS (acquired immune deficiency syndrome) in places such as North America and Western Europe One, exemplified by the sponsors of Proposition 64 on this week's Californian ballot, is that AIDS has arisen because some social groups follow unusual sexual practices (homosexuality) or inject themselves with drugs, that AIDS would go away if these practices were stopped and that society should meanwhile protect itself by casting out the sick The other view is that AIDS has spread so rapidly since it was first recognized as a distinct disease in mid-1981, and is now spreading so rapidly outside the groups originally infected, that it can be only a matter of time before a substantial proportion of the general population, women and children as well as men, succumbs If the second view should prove correct, and if no generally applicable remedy or prophylactic comes on the scene, the damage done to modern society by AIDS would compare with that expected from, say, a nuclear war between the major powers

That is the background to the publication last week of the report of a committee sponsored jointly by the US National Academy of Sciences and the Institute of Medicine One of the two committee chairmen is Dr David Baltimore, director of the Whitehead Institute at Massachusetts Institute of Technology and, piquantly, one of the two independent discoverers (with Dr Howard Temin of the University of Wisconsin) of the role of the enzyme reverse transcriptase in the replication of viruses whose genetic information is carried by RNA, of which the AIDS virus is one The document (see p 3) is a model of clarity and careful assessment of daunting problems It denies the first and simplistic view of AIDS and how to deal with it Properly, it is agnostic on the second view of the distant future But that does not prevent it from urging, irresistibly it would seem, that the US government should vastly increase its spending on the AIDS epidemic In round numbers, it wants to see an extra $1,000 million a year spent on education and public health and as much again on research

The seriousness of the problem cannot be dodged The US Public Health Service estimates that 9,000 US citizens will have died of AIDS during 1986, doubling the cumulative toll at the beginning of the year During 1991, on the same set of estimates, there will be some 54,000 deaths in the United States, almost all of them recruited from the 1 to 1 5 million people thought already to have been infected Elsewhere, the pattern is much the same, but lags behind that in the United States by a year or two In Britain, for example, the number of known cases has doubled each year since 1983, and now amounts to just over 500, but there are some tens of thousands of infected people to fill the ranks of the dying in the years ahead

Plague

So is this the plague returned? Much depends on what is meant by that concept, of which one essential ingredient must be that there is little that can be done about it What should chill the spines of the US Congress elected this week is the judgement of the academies' committee that there is no quick therapeutic or prophylactic fix in sight, last month's wonder drug, AZT (azidothymidine) is at best a palliative that that could prove unacceptably toxic, while a vaccine against the virus responsible (now called HIV) is at least five years away Meanwhile, on the estimates of the US Public Health Service, AIDS will be responsible for between 1 and 2 per cent of deaths in the United States five years from now The Baltimore report is right to emphasize the great social and economic cost of that toll, with its peculiar age-distribution between early adulthood and middle age, but what is the chance that the death-rate might grow to be an order of magnitude greater? That is what the US and other governments will want to know While AIDS is so new, it is too soon to tell, but an answer will emerge over the next few years Two technical questions are crucial

Bad news

- What proportion of those asymptomatically infected will eventually succumb? Since the introduction two years ago of blood tests for the detection of antibodies against HIV, it has become clear that infection is not immediately followed by AIDS This is most directly shown by the retrospective examination of blood collected both in California and Central Africa in 1978, three years before AIDS was recognized for what it is, yet showing evidence of antibodies The US Public Health Service's estimate of the development of AIDS in the United States supposes that 20–30 per cent of those with antibodies will convert to overt AIDS during the next five years, but that is but an educated guess based on five years experience of AIDS, only two of them with the benefit of antibody tests The academies' committee prefers the estimate of 25–50 per cent of conversion to overt AIDS within 5–10 years of the appearance of antibodies in the blood But what if the conversion rate is more like 100 per cent over, say, two decades? Nothing in the data so far collected can exclude that possibility, which would be very bad news
- How effective is heterosexual intercourse as a means of infection? There was a sprinkling of women among the first few handfuls of AIDS cases reported in the United States, but these could at the outset be explained as exceptions to the rule that AIDS is a venereal disease of male homosexuals (or else is acquired by blood transfusion, haemophilia treatment or the use of second-hand syringes for injecting illicit drugs) But this view, never plausible, is no longer tenable The academies' committee refers to substantiated cases in the United States of heterosexual transmission from men to women and in the other direction In many African countries, as well as in Haiti in the Caribbean, women and men are more equally infected In due course, if the social groups now considered to be especially at risk (male homosexuals, intravenous drug users and users of blood products) are set to one side, that will be the case in advanced societies as well What will matter is the degree to which the infection spreads among the heterosexual population free from other complications The academies' committee says that at present there is no worthwhile evidence bearing on this question But if the answer should be gloomy, the implication could be that mere containment of the spread will be impractical That, too, would be exceedingly bad news

So how is it possible to fight an infection potentially so dangerous for which, now, there is neither prophylactic nor cure? The academies' committee agrees with the drafters of Proposition 64, which would make AIDS a notifiable disease, on just one point in the short term, the only possible stratagem is to reduce the rate at which the infection can spread (Historians will note the humiliating similarity with the stratagems used to contain the Black Death) Then two two groups part company

The committee explicitly rejects proposals for the compulsory testing of the social groups considered most at risk (followed, perhaps, by the compulsory incarceration of those found positive in quarantine camps) not only on libertarian grounds but, more cogently, on the grounds that such hare-brained schemes could not work

There are two grounds for this position First, there is a variable, undetermined and perhaps long interval after infection before the appearance of antibodies (seroconversion) to HIV in a person's blood That means that even ideally efficient tests could not identify all infectious carriers More important, there is ample evidence that attempts at coercion in this field would be counter-productive, even now, without it, the social stigma of being infected with HIV means that some patients fail to report to their physicians and, for understandable if unforgivable motives, that physicians fail to report cases in their care to the authorities Compulsion would be a way of making the disease seem to go away by driving it underground where it would be an even greater danger

The academies' committee instead puts its money (or, rather, the federal government's) on education, demanding urgent efforts to enlighten not merely the groups at risk but the other members of the communities to which AIDS has or will spread There is some good news General enlightenment has taken the edge off the fear, rife even two years ago, that a person could catch AIDS from being in the same room as a patient There is also some sketchy evidence that the behaviour of homosexual males has been changed by the spread of an understanding of the disease among those at risk, much of that accomplished by voluntary self-help groups (Even so, the committee cannot decide whether the recent flattening of the rate of infection among homosexuals in New York City and California is a consequence of changed habits or, equivalently, the saturation of the infective population) The committee is right to say that there are two other groups to which public education should be directed intravenous drug users (who seem mostly beyond the ken of most social institutions) and those still at school on the threshold of adult sexual life The committee might have made more of the threat posed by prostitutes

Irony

These are daunting problems, loaded with irony If the new US Congress takes the academies' report seriously, as it must, it will find itself having to spend as much on AIDS education as its predecessor chose to appropriate for the great war on drugs At least it may be some comfort that, in respect of the transfer of HIV by means of used hypodermic needles, the two wars will overlap Yet the committee is right to emphasize that, with the practice of screening blood products to eliminate blood from infected donors and the declining pace of new infection among male homosexuals, the intravenous drug users are the next most important reservoir of infection Who will be able to reach them?

The young, even though they turn up at schools most days, are in some ways even less approachable AIDS is a venereal disease that may be acquired in the course of sexual intercourse of any kind, but how are young people without sexual experience to be warned that it may be a dangerous as well as a natural practice? The committee comes out squarely for explicit sex education in the public schools and for the replacement of euphemisms such as 'intimate contact' by frank statements of what their users mean, in the vernacular if need be That will mean more classroom four-letter words

The committee has no choice, yet this is where its troubles will begin, it acknowledges that "political opposition and bureaucratic intransigence" at present limited school sex education to a few enlightened school jurisdictions, but seems not to appreciate that the opposition is as likely to harden as to melt away, now that there is AIDS as well as all those other problems British readers of the report will know the difficulties, for this week in which their government will have placated its supporters opposed to sex education by transferring from local education authorities and head teachers to supposedly less free-thinking school governors the right to decide on sex education in the curriculum Fair play, the politicians are in a nasty cleft stick

The stakes are high, they risk that AIDS might spread beyond the point at which it could be contained Their constituents, as always ready to believe that it would be simpler to get from A (now) to B (tomorrow) by starting from somewhere else, say they would prefer that teachers on the taxpayers' payroll should tell innocent children about the virtues of the nuclear family than about the condom as a barrier to venereal infection But they, too, have no choice but to fall in with the logic of the academies' conclusion that only the most explicit sex education for the young offers hope of avoiding what may be a catastrophe Issuing chastity belts for all children would be the other way

From all this, it is possible that some good news may emerge The remarkable feature of AIDS infection in the past five years is that so much has been learned about it so quickly It is, for example, great good luck that the discovery of reverse transcriptase preceded the emergence of AIDS as a disease It is also remarkable that so much has been done, in a mere three years, to identify and characterize the virus The blood test, with all its defects, helps Yet the provision of a prophylactic, let alone of a cure, will require a more sensitive and complete understanding of the human immune system than there is at present The committee makes a strong case for giving research a chance, will governments agree?

Ignorance

Maybe, but maybe not In Washington, the congressional committees will call the shots, they, not the likes of Baltimore, have the cheque-books in their fists But congressmen will not be pleased, early in 1987, to be confronted with the demand of the committee academies' $2,000 million a year for the sake of saving civilization, especially when the Strategic Defense Initiative will be asking for even more, backed by a tighter prospectus, for ostensibly the same purpose The best way to choose between projects such as these is to calculate the downside risks If SDI should come to nothing, the world would probably be no more dangerous than it is (and might even be safer), but if the search for treatment and prophylaxis for AIDS should fail, calamity will be on the cards

The next few years, while there accumulate the data on which it will be possible to estimate the eventual penetration of the general population, will be crucial It is a brief breathing space, one in which intelligent policies could help decelerate the spread of the disease and pave the way for techniques that will be needed, in any case, for decades to come It will be a curious period for us all, not only for politicians Somehow it will be necessary to combine a sense of urgency with a sense of the importance of the civility that makes society worthwhile The danger is that some will be overwhelmed by the urgency of the problem to the point at which illiberal ways take hold The latent and not-so-latent hostility to homosexuals is a constant danger So are groundless attempts to keep children with AIDS out of the public schools Heavy hints by insurance companies (as in Britain at the weekend) that voluntary blood tests will be taken as presumptive evidence of sexual risk, are both inequitable and counter-productive What we must remember is that, as in the defence of Western Europe, battles that destroy what they are intended to preserve are not worth winning □

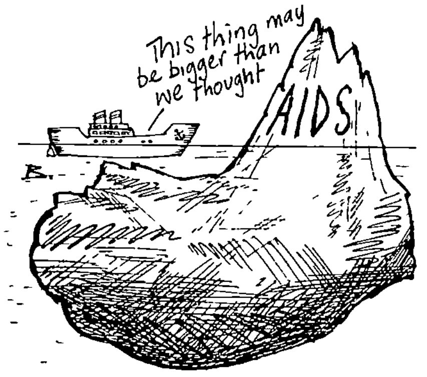
AIDS

Academies demand urgent public education

Washington

AN immediate and massive public education campaign is needed to slow the spread of acquired immune deficiency syndrome (AIDS), according to a report released last week by the Institute of Medicine (IOM) and the National Academy of Sciences* In addition to the $1,000 million a year required to pay for this educational campaign, the report also urges that support for AIDS research should be increased to $1,000 million a year by 1990 Without decisive action, IOM president Samuel Thier says, the epidemic may "snowball into an even greater catastrophe"

Following it annual meeting in 1985, the Institute of Medicine determined that it should provide direction for the US effort to combat AIDS With Thier as its new president, the institute together with the academy made the development of recommendations for dealing with the AIDS epidemic a priority Last week's 374-page document was produced in slightly more than seven months David Baltimore of the Whitehead Institute and Sheldon Wolff of Tufts University Medical School co-chaired the panels responsible



This thing may be bigger than we thought
AIDS

Although the report praises government support for research on the biology of the AIDS virus (HIV, or human immunodeficiency virus), the report is critical of the government's effort in public health In particular, federal educational efforts are dubbed "woefully inadequate" Until an effective vaccine is developed, Wolff says that educating the public is the best hope for curbing the disease The report reckons an effective campaign involving all levels of government as well as industry and private organizations will cost about $1,000 million a year

Almost as if anticipating the IOM report's criticism, Surgeon General C Everett Koop called for an increased educational effort in a report released one week before the IOM report Declaring that "the silence must end", Koop says it is no longer possible "to sidestep frank, open discussions about sexual practices — homosexual and heterosexual" Education must be extended to prepubescent children as well as to their parents, according to the Koop report

Wolff describes the surgeon general's report as "clearly a step in the right direction" Both reports urge the use of condoms for men who are not certain if their partners are infected with HIV

A vexing problem in determining how best to orchestrate an educational campaign against the spread of AIDS is the lack of information about sexual practices Baltimore suggests that a significant portion of new research money should go to social science research in that area Sexual intercourse remains the most common means of transmitting HIV Although the disease primarily afflicts homosexuals, the Public Health Service estimates that heterosexual transmission will account for 10 per cent of new cases by 1991

As well as increased education, the report makes several specific recommendations about new public health efforts that should be attempted As non-sexual transmission of AIDS occurs primarily through sharing of needles used for injection of intravenous drugs, the government should investigate the possibility of providing clean needles free of charge to users of illegal drugs In strictly financial terms, the report says it is cheaper to treat a drug addict than an AIDS patient

The report also calls for increased surveillance for both AIDS and AIDS-related complex (ARC) cases, and voluntary testing of serological status for individuals who may have been exposed to the virus The report declares that mandatory blood tests are inappropriate in most cases, the armed forces being a notable exception Calling AIDS an international problem, the IOM report urges the United States to spend $50 million a year on efforts to control the disease throughout the world

The report recommends that a new National AIDS Commission be established to coordinate federal efforts in combating AIDS But Baltimore does not see this office as playing a role in directing research He says that research proposals initiated by investigators make the best use of scientific talent in learning more about HIV, but that a directed approach would be appropriate for a vaccine development project

Federal funding for AIDS research has been nearly doubling in recent years In 1984, the government spent just over $61 million on AIDS research For 1987, that figure will jump to $410 million Gary Noble, now coordinating AIDS activities for the Public Health Service, will not speculate whether that rate of increase will be sustained Noble agrees in principle with many of the IOM report's conclusions, but says new therapeutics or unexpected discoveries about HIV could change matters

By 1991 the Public Health Service estimates there will be 270,000 cases of AIDS in the United States There are already an estimated 1 5 million people infected with HIV Academy president Frank Press says there is a need for a "national strategy to respond to a national crisis" Thier hopes the reports will mark the "turning point in the nation's approach to AIDS"

AIDS drug test

SHROUDED by a veil of patent secrecy, an antiviral agent that is claimed to have more laboratory activity against the AIDS (acquired immune deficiency syndrome) virus than other anti virals is about to undergo animal toxicity tests in Britain. Porton International, the company that is developing the drug, hopes that it will pass the toxicity tests and can rapidly be tested by patients, using the US Food and Drug Administration's special fast-track procedure for potential AIDS drugs.

Porton will not, however, reveal anything of the chemical nature of the drug, which is named human immune virus antiviral. It is a natural substance extracted from a microorganism, and first emerged during a screening for antiviral compounds at the University of California (exactly where and by whom, Porton will also not reveal). Porton has acquired the rights to develop the drug which it is doing in collaboration with the Centre for Applied Microbiology and Research at Porton Down in Wiltshire, known for its expertise in the large-scale culture of microorganisms

Peter Newmark

- THE British government, which this week set up a cabinet committee under Lord Whitelaw to look into the problems posed by AIDS is also under pressure to increase the publicity given to it and to consider a mail-drop to every home in the United Kingdom

Critics of government strategy claim that the publicity campaign conducted in the British press since the spring has been a failure, as a high level of ignorance about the disease still prevails Advertisements were placed in national newspapers this year, and AIDS publicity has been funded through a £2 5 million budget ☐

Test-ban seismology

Soviet visit to US cut short

Washington

THE unique private effort to monitor nuclear testing in the United States and the Soviet Union is off and running, with three seismic monitoring stations now established near the Soviet test facility in Semipalatinsk But phase two, due to start next week with the arrival of five Soviet seismologists for site selection in this country, will proceed as planned The US State Department has limited the Soviet delegation's stay to one week, and has refused to permit a planned visit to potential monitoring sites

The monitoring effort comes from an agreement signed last spring by the Natural Resources Defense Council (NRDC), a private non-profit organization, and the Soviet Academy of Sciences (see *Nature* **321**, 638, 1986) Phase one of the agreement was completed this summer when NRDC scientists established seismic monitoring stations at Karkaralinsk, Bayanaul and Karasu near Semipalatinsk

Preliminary measurements have been taken at each site, and construction is nearly completed on 300-ft boreholes for high-frequency seismometers Returning last week from a visit to the Soviet sites, NRDC senior scientist Thomas Cochran declared the Soviets had done "an exceptional job, spending some $150,000 for construction of each station"

The US government, by contrast, has not welcomed the NRDC effort The administration feels that arms control issues should be carried out on a government-to-government basis, not by private organizations The goal of the NRDC/Soviet Academy effort is "to get the verification issue out the way", says Cochran But the State Department believes that there is a better way to monitor nuclear testing The government's approach is a a hydrodynamic yield measurement technique called CORRTEX, for Continuous Reflectometry for Radius versus Time Experiment

A coaxial cable is placed in a hole parallel to the nuclear device After the explosion, the rate of change in the cable length is used to estimate the yield of the device President Reagan last March offered to demonstrate CORRTEX for Soviet scientists, but so far that offer has not been accepted The State Department made viewing a CORRTEX demonstration a condition for granting the two-week visa sought by the Soviet seismologists, but Cochran says that Soviet officials decided that the seismologists would be "inappropriate" for determining the value of the system

During their visit, the Soviet delegation will also visit Teledyne Geotech and Refraction Technology in Dallas, manufacturers of monitoring equipment for the monitoring effort NRDC expects to take delivery of the new equipment later this month, and after testing it should be installed on site in the Soviet Union by early next year The Soviet seismologists will also discuss with seismologists at the Scripps Institution at the University of California, San Diego, the selection of monitoring sites near the US Nevada test facility Three potential sites have been identified at Nelson and Railroad Valley, both in Nevada, and Deep Springs, California

Joseph Palca

British seek funds

THE British team, invited by the Soviets to join the Americans in monitoring nuclear tests at Semipalatinsk, is attempting quickly to raise the bulk of the £200,000 it will need for the coming year.

Two committees will steer the project, one composed of eminent scientists with a reputation for raising money and the other of seismologists Seismologists from the Universities of Leeds, Liverpool and Leicester have already offered to help.

The invitation was extended by the Soviet Academy early last month to two British scientists visiting Moscow, Dr Frank Barnaby, former director of the Stockholm International Peace Research Institute, and Dr Jeremy Leggatt, lecturer in Earth sciences at Imperial College in London.

Apart from Barnaby and Leggatt, the project team includes Dr David Davies, a seismologist and former editor of *Nature* who is now director of the Dartington North Devon Trust, Professor Martin Rees of the Institute of Astronomy, Cambridge, and Joseph Rotblat, emeritus professor of physics at St Bartholomew's Hospital Medical School in London.

The British team should be in place by mid-December, before the test-ban treaty lapses at the end of the year. If the group can attract sufficient funds, two monitoring positions will be created, manned by two people at any one time.

Because of the political aspects of the project, no research council support will be available, Leggatt says, in spite of the scientific value of the proposed collaboration between British and Soviet seismologists. It is hoped, however, that Quaker and US foundations will provide support.

The equipment will all be supplied from the West, although the Soviets will have access to data retrieved. The British monitoring positions will collect data on the crustal struture below the test sites, particularly seismic wave propagation

Bill Johnstone

Strategic Defense Initiative

Academicians doubt efficacy

Washington

SCIENTISTS at Cornell University announced last week the results of a commissioned survey on views held by members of the National Academy of Sciences about the Strategic Defense Initiative (SDI) The principal conclusion is that 78 per cent of those responding believed that the prospects were "poor" or "extremely poor" that SDI can be made "survivable and cost effective at the margin" within the next 25 years, while only 4 per cent believed the chances of success were better than even Ninety-eight per cent believed SDI could not provide an effective defence of the US population within 25 years in the face of Soviet attempts to thwart it, and 94 per cent believed that goal to be impossible even if the Soviets froze their arsenals at current levels

The survey has caused some discomfort at the academy because it does not represent an official view, although the Cornell scientists have been careful to make the distinction clear, academy staff feel it is now perceived as opposed to SDI The study, designed and conducted by the Cornell Institute for Social and Economic Research, was instigated by Peter Stein, a physics professor at Cornell, and paid for by the Ploughshares Fund of San Francisco and the MacArthur Foundation The survey was sent to all 663 academy members in the physical, mathematical and engineering sciences, and responses were received from 71 per cent

The study nevertheless received some influential support from academy members A covering letter sent out with the questionnaire, signed by well-known Cornell members, urged recipients to give a few minutes to respond, saying that a "definitive poll" could provide a "useful contribution to one of the most vital science policy issues of our time"

The administration, well used to academics querying SDI, is unlikely to be immediately influenced by the survey But Congress is another matter it recently voted $3,500 million for SDI research in fiscal year 1987, $1,900 million less than the administration requested But for a one-vote close call, the figure would have been only $3,300 million, and doubts about SDI's feasibility played a significant part in reducing the budget Senator William Proxmire (Democrat, Wisconsin), a prominent SDI critic who was invited to the press conference at which the survey was announced, said "the best scientific minds of the country are telling [the President] loud and clear that Star Wars won't work and that it's a waste of money"

Tim Beardsley

Robots

Britain tries to catch up

BRITAIN is to have an Advanced Robotics Research Centre to develop new techniques for automatic manufacture and to cultivate the wider acceptance of robot technology, in which Britain still lags behind many of its major industrial competitors.

The announcement of this development coincides with the publication on 5 November of a study of the uses of robots in Britain, which concludes that there are still many fewer than 1,000 manufacturing companies using robots, roughly one robot for every 40 factories. The robot population of Britain at the beginning of the year is estimated at 3,200, fewer than the annual increase of robots in West Germany alone during 1985.

The new research centre will be supported jointly by the British government and between 20 and 25 industrial partners. Possible locations include the universities of Glasgow, Salford and Edinburgh and the UK Atomic Energy Authority research establishment at Harwell. The budget will be determined by the number of industrial partners in the venture.

The plan is that the institute will have a research staff of two dozen, concentrating on advanced manipulators, sensors (visual, tactile and acoustic), navigational systems for self-propelled devices, computer systems software and standards for control and artificial intelligence or Intelligent Knowledge Based systems. The new group will also investigate advanced designs intended for use in hostile environments unsuitable for people, for example, nuclear installations.

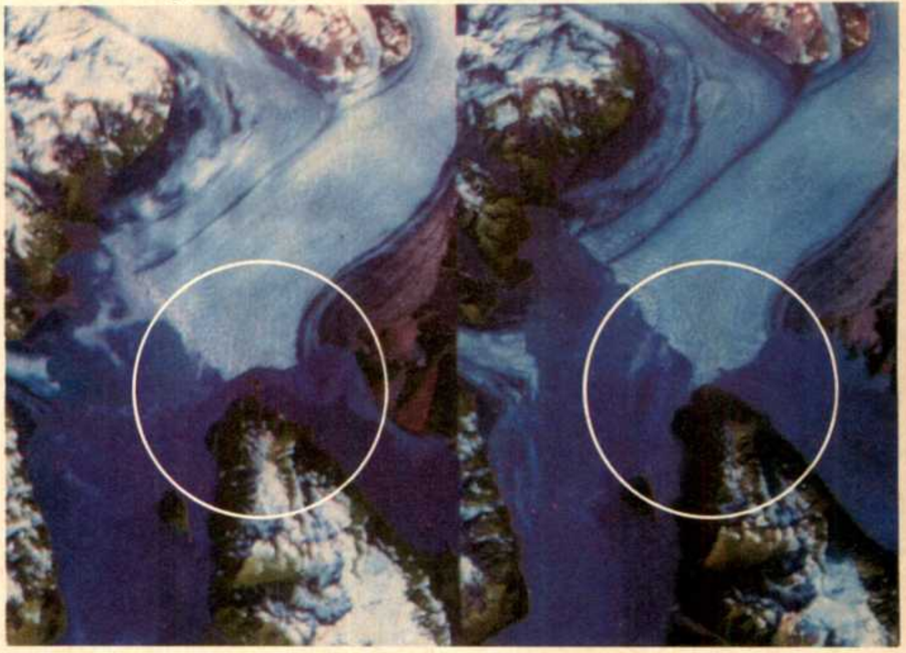
The study published last week, which advocates the setting up of a centre along the lines now proposed, was carried out by the London-based Policy Studies Institute on the initiative of the British Robot Association with support from the Gatsby Charitable Foundation, the Department of Trade and Industry and the National Economic Development Office.

The report says that there were industrial robots in about 740 manufacturing plants at the beginning of 1986, but that most of the plants belonged to larger companies. Only 12 per cent of robot users employ fewer than 100 people. On the other hand, a third of the users are very large manufacturing plants employing more than 1,000 people.

The report says that part of the problem in Britain has been the high cost of the development of robots, the lack of technical support and the poor reliability of designs. The new robot centre is meant to offer a cure for some of these ills.

Bill Johnstone

Alaska glacier seals fate of fiord wildlife



WHEN the Landsat 5 image on the left was taken on 7 August last year, water from the Russell Fiord in Alaska (on the right in each image) could flow freely into Disenchantment Bay (left). But by 11 September this year, as shown in the image on the right, the Hubbard Glacier had sealed off the fiord, forming Russell Lake. Movement of the glacier could eventually fill Disenchantment Bay and the larger Yakutat Bay with ice.

This event is "probably the largest natural alteration in ocean, glaciers, lake and rivers in North America within our lifetimes", says US Geological Survey glaciologist Larry Mayo. The inhabitants of Yakutat on the Pacific are probably not in any danger, but saltwater fish and wildlife, including seals, trapped in Russell Lake will almost certainly die as the water becomes deoxygenated.

In these images vegetation shows up geen, rock and oils a red and water/ice are in blue and white shades. □

US education

Plan to license teachers

Washington

THE US National Science Teachers Association (NSTA) is planning a certification scheme to establish basic qualifications for all science teachers. The plan has been prompted by a study showing that half of newly hired teachers in the United States are unqualified and that about a third of all science classes are staffed by unqualified teachers.

The immediate problem is that state certification requirements are now" largely ignored" in hiring and assignment decisions, according to Bill Aldridge, executive director of the association. Although participation in the certification scheme will be voluntary, Aldridge hopes that it will put pressure on states to improve and enforce their own certification standards.

The association also hopes that a further benefit of its scheme will be that specialist teachers in high schools will be more accurately assigned to suitable classes. Another survey by NSTA showed that 65 per cent of physics teachers, 52 per cent of chemistry teachers and 37 per cent of biology teachers are assigned to classes other than those they are qualified to teach.

To qualify for NSTA certification, teachers will have to hold an appropriate bachelor's degree and will have to demonstrate a strong background in statistics, mathematics and the application of computers to science teaching. In-service training and three years experience will also be required.

NSTA's standards have been adopted by the National Council for the Accreditation of Teacher Education, and will be the basis for future decisions on the accreditation of college and university science teacher training programmes.

School administrators are likely to welcome the certification scheme, although Gary Marks of the American Association of School Administrators is concerned that the pressure to raise standards may impose greater financial burdens on school systems. He also asks whether, if certification becomes standard, school administrators will be forced to drop courses when certified teachers are not readily available.

Carol Ezzell

US oceanography

Research centre born in storm

Washington

THE US Navy's new Institute for Naval Oceanography (INO) in Bay St Louis, Mississippi, opened last month with ambitions of becoming the leading ocean modelling research centre in the 1990s. But critics are still bitter at the decision by the Navy to put the institute at the unpopular Mississippi site rather than at Monterey, California, the choice of the great majority of the experts consulted. Some say that the Mississippi site, which is far from any major university and suffers from extreme heat and humidity in the summer, will be a "major impediment" to hiring the best researchers in the field.

According to consultants who worked on the project, Bay St Louis was not even the first choice of Secretary of the Navy John Lehman. The final decision was not made until 18 months ago, and many see it as reflecting the influence of Mississippi Senator John Stennis, a powerful Democrat on the Senate Armed Services Committee. Stennis is seen as the force behind a long-term agglomeration of Navy oceanographic facilities at Bay St Louis.

Some oceanographers say that opportunities for INO collaboration with the Navy's Fleet Numerical Oceanographic Center and its postgraduate school at Monterey would have been better than with the Navy Oceanographic Research and Development Activity (NORDA), already at the Bay St Louis site. (Researchers staged a protest several years ago when part of the Naval Research Laboratory in Washington was moved to Bay St Louis to become part of NORDA.) And the Monterey climate is as famed for being pleasant as that of the Mississippi delta is for being unpleasant.

Even so, a member of Stennis's staff denies that political pressure had been brought to bear, saying the decision reflected priorities decided by the Navy several years ago.

INO will work on all aspects of ocean modelling and prediction, using supercomputers at other centres until it acquires in about two years its own 'class 7' supercomputer, the generation beyond the most advanced Cray machine, the XMP 4800.

Although the centre was formed primarily to improve predictions for naval operations, its director, Christopher Mooers, foresees many spin-offs to civilian applications. At present, ocean predictions are limited by atmospheric variability, and a major goal will be to integrate atmospheric data with oceanic models. Mooers says that working at INO will "appeal to those with a pioneering spirit".

The immediate goal, for the year or so ahead, is to provide regional predictions. The centre will be fully operational in the early 1990s. The institute is timed to make best use of the expected welter of new remote-sensing ocean data in the next decade, when the National Aeronautics and Space Administration's TOPEX satellite will be in service and the US Navy launches its NROSS oceanographic satellites. Walter Munk, chairman of the National Academy of Sciences' ocean studies board, endorses the formation of the institute, saying of ocean modelling that "no-one knows yet how well it can be done". INO will also integrate data from acoustic sensors and *in situ* measurements.

INO has been established at the National Space Technology Laboratories, a remnant of the Apollo space programme, with an initial budget of $4 million and a staff of 30. It is expected to expand to about 50 within five years, and will set aside about $1 million each year to support work at other institutions. Mooers specifically welcomes proposals for collaborative research with overseas scientists.

Many academic oceanographers say quality suffers at Navy-run establishments, partly because military directors are often on short-term appointments. Mooers says that the NCAR consortium "provides our academic quality assurance". But other oceanographers are more cautious, saying the institute's potential to become a world leader will be met only if the Navy resists the temptation to keep it focused on short-term goals.

Tim Beardsley

Soviet Union

Russian criticism begins at home

THE election of Academician Gurii Marchuk as president of the Soviet Academy of Sciences has been celebrated with massive self-criticism. Instead of dwelling on recent achievements, both the report on the state of the academy presented by vice-president Vladimir Kotel'nikov and the ensuing discussion stressed deficiencies in performance ranging from overstaffing with inept personnel to a shortage of computers of "average productivity".

In some cases, although no names were mentioned, the faults seem to have been at least in part associated with the attitude of the outgoing president, Anatolii Aleksandrov, towards Western science. It was Aleksandrov's contention that Soviet science can achieve world leadership in all fields on its own efforts, and that Soviet participation in international cooperation programmes should be undertaken only to further detente and to avoid duplication of effort. Now, however, Kotel'nikov's report stresses that the CoCom restrictions on the transfer of Western state-of-the-art instruments constitutes a serious problem and the Soviet instrument manufacturing industry cannot satisfy the needs of the scientific community. Some time ago, said Kotel'nikov, the academy raised the question of how to expand the development and manufacture of scientific instruments but it has made little progress so far, although capital investment in the academy's own instrument-making base is to increase by 150 per cent during the present five-year plan.

Similarly, Academician Boris Paton, president of the Ukrainian Academy of Sciences, urged the importance for Soviet planners of a proper understanding of technological developments in the West. Although technology is "the most holy of holies to which there is virtually no access", Soviet scientists must use all "possible and, so to say, impossible" means of establishing this information.

Paton's suggestions raise a number of interesting questions. The Soviet Union already has an extensive information network, administered, in the civil sector, by the State Committee for Science and Technology, and in the military sector by the Commission for the Defence Industry. Information on Western science and (in particular) technology, obtained by debriefing scientists returning from visits abroad, is fed into these twin networks through their permanent representatives in the research institutes. The reverse engineering of Western prototypes coming into Soviet hands is likewise carried out under the auspices of these bodies. What Paton appears to imply, therefore, is that either the academy scientists have not been sufficiently zealous in their efforts to acquire useful technological information, or that the analysis carried out by the existing information services is inadequate.

As far as Soviet science is concerned, most criticisms proved to be aspects of the endemic Soviet theme: the failure to implement research results in manufacturing and agricultural practice.

But some practical suggestions were proposed. Academician Vladimir Tuchkevich noted that, although academic resesearch institutes are encouraged to serve the needs of industry, they have no financial incentive to do so. Instead, the research is financed by the state, and the results, including any hardware produced by the research team, either have to be handed over free of charge or sold at less than cost price. It would be better, Tuchkevich urged, if the research institute could charge industry for what it has produced, return the initial investment to the statae, and use the profits for its own needs.

Vera Rich

Japanese physics

Accelerator swings into action

Tokyo

JAPAN's High Energy Physics Laboratory, KEK, has achieved a world's first by boosting the electron beam in the 3-km main storage ring of TRISTAN to 25.5 GeV during a test run of the accelerator. If tests of the positron beam go according to plan, the first collision experiments will begin before the end of the year and TRISTAN can enjoy a spell as the world's number one electron–positron collider. But plans for electron–proton collisions have been dropped in the face of competition from West Germany's HERA electron–proton collider.

TRISTAN, which has taken five years and Y87,000 million (£388 million) to build, consists of a 2.5-GeV linear accelerator that feeds electrons and positrons into an accumulator ring where they are boosted to 6.5–8 GeV before injection into the main ring. Radio-frequency cavities in four long, straight sections of the main ring accelerate the counter-rotating bunches of electrons and positrons which can be squeezed by superconducting magnets and smashed together in the middle of each straight. But as the electrons/positrons traverse the bends of the main ring near the speed of light, energy is released as synchrotron radiation, a loss which limits the power of the accelerator.

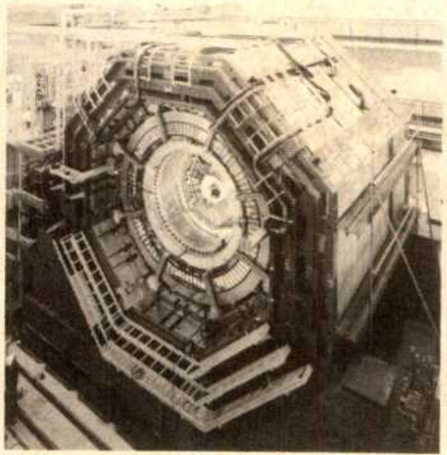
The record just set by TRISTAN exceeds the maximum of 23.5 GeV achieved by the PETRA ring in Hamburg, although TRISTAN's electron-beam current was only 0.4 mA. The KEK scientists are racing to raise this to 2–3 mA, the minimum required for collision experiments. VENUS, the first of TRISTAN's four detectors, is "about 70 per cent complete" and the first electron–positron collisions may be performed on schedule at the end of this month, according to KEK director Tetsuji Nishikawa.

Commissioning of TRISTAN ahead of US and European rivals will be a major triumph for Japan's high-energy physicists who have been struggling to put Japan back on the map since the end of the Second World War when the country's four largest cyclotrons were dumped at sea by US marines because someone in Washington feared they could be used to make atomic bombs.

But TRISTAN's dominance may be short-lived. The Stanford Linear Collider (SLC) has already taken electrons up to 37.5 GeV towards its target of 52 GeV with the prospect of electron–positron collisions in February or March 1987.

Nishikawa, however, is confident that with its higher luminosity and wider, stable beams TRISTAN will have advantages over SLC — the beams of SLC are only about a micrometre across and there will be difficulty in making them collide.

Among the particles TRISTAN may find are the top quark, Higgs particle, supersymmetric particles and fourth generation leptons and quarks, if they exist. But KEK scientists will also be looking for "totally unexpected and new phenomena in the new energy frontier".



TRISTAN will continue to consume large amounts of money, mainly in the form of electricity bills. In this fiscal year (until April 1987), Y6,000 million (£27 million) has been allotted by the Ministry of Education, Science and Culture for operation costs, enough for 1,000 hours. KEK is hoping for 1,800 hours at a cost of Y10,000 million in fiscal year 1987.

Next March, 40 radio-frequency cavities will be added to the main ring, bringing the beam energy up to about 28 GeV, and the addition of superconducting cavities in 1988 is expected to boost this to 33 GeV, a matter of months before the LEP electron–positron collider ring at CERN is due to come on line at 50 GeV.

KEK also plans to use the main ring as a 10-GeV synchrotron radiation source, which could be another first for Japan, but the most ambitious plan of all for TRISTAN has been abandoned.

Since TRISTAN was first proposed in 1973, it had been intended to include a proton storage ring alongside the electron–positron ring to allow electrons at 30 GeV to collide with protons of 300 GeV. Space for the proton ring was made in the 3-km tunnel of the main ring and a 12-GeV proton synchrotron built at KEK in 1976 would have provided the protons. But West Germany's decision to build the larger HERA electron–positron collider at Hamburg by 1990 has apparently caused Japan to change its plans. The main reason, says Nishikawa, is that HERA, which will smash 30-GeV electrons against protons of at least 820 GeV (with even higher energies in prospect), will be much more likely to reveal quark structure.

David Swinbanks

One-way crossing

THE British electrical utility, the Central Electricity Generating Board, began last Thursday to draw some 1,500 MW of cut-price electricity from France along four pairs of high-power cables recently laid across the English Channel. The French generating system is now more than 70 per cent nuclear and has over-capacity. Under the 1–2-year deal between CEGB and its opposite number, Electricité de France, the British board will take at least 1,000 MW continuously at a cost 25 per cent below 'average' generating costs in Britain, and 'part' (typically 500 MW according to CEGB) of the remaining 1,000 MW capacity of the link at the same cost. The link is two-way, so British electrical exports to France are possible, but none is planned. The power thus to be drawn by Britain from France exceeds the capacity of a single pressurized water reactor, such as that CEGB wishes to build at Sizewell in Suffolk, and on which the planning enquiry report is now imminent.

Robert Walgate

What anniversary?

THE BBC (British Broadcasting Corporation) is this week celebrating the fiftieth anniversary of its first television broadcast with a series of past performances almost calculated to meet the Conservative (and government) party's charge than the BBC's news reporting is biased; past politicians are mocked with an even hand. But readers should judge for themselves, from this extract from *Nature* (**78**, 151; 1908), whether the BBC is celebrating the right anniversary. □

Distant Electric Vision.

REFERRING to Mr. Shelford Bidwell's illuminating communication on this subject published in NATURE of June 4, may I point out that though, as stated by Mr. Bidwell, it is wildly impracticable to effect even 160,000 synchronised operations per second by ordinary mechanical means, this part of the problem of obtaining distant electric vision can probably be solved by the employment of two beams of kathode ray (one at the transmitting and one at the receiving station) synchronously deflected by the varying fields of two electromagnets placed at right angles to one another and energised by two alternating electric currents of widely different frequencies, so that the moving extremities of the two beams are caused to sweep synchronously over the whole of the required surfaces within the one-tenth of a second necessary to take advantage of visual persistence.

Indeed, so far as the receiving apparatus is concerned, the moving kathode beam has only to be arranged to impinge on a sufficiently sensitive fluorescent screen, and given suitable variations in its intensity, to obtain the desired result.

The real difficulties lie in devising an efficient transmitter which, under the influence of light and shade, shall sufficiently vary the transmitted electric current so as to produce the necessary alterations in the intensity of the kathode beam of the receiver, and further in making this transmitter sufficiently rapid in its action to respond to the 160,000 variations per second that are necessary as a minimum.

Possibly no photoelectric phenomenon at present known will provide what is required in this respect, but should something suitable be discovered, distant electric vision will, I think, come within the region of possibility.

A. A. CAMPBELL SWINTON.
66 Victoria Street, London, S.W., June 12.

European research

Applicants galore, but few grants

Four out of five applicants for research grants from the European Commission in Brussels fail to get a single ECU, although many of the project proposals are worthy of support, a Commission official warned British hopefuls in London last week. The occasion was organized by the Cabinet Office to give a clearer indication to British scientists and industrialists of the support available from Brussels and how to apply for it.

Apart from the shortfall between good applications and the support available, of which the Commission repeatedly complains when seeking more cash from the Council of Ministers, there can be long delays before decisions are reached. Successful researchers often receive the cash they need only in the year after they have spent it. The Commission admits its deficiencies and has set in train a programme of 'acceleration and simplification' to tidy up its act.

According to Commission administrator Roderick Hurst, the new 'framework programme' for Commission research and development now before the Council of Ministers will also improve matters by introducing majority voting on individual research programmes, so speeding up the time between a Commission proposal and final approval by the Council of Ministers.

Hurst says that the most frequent criticisms are of the lack of transparency in decision-making; the complexity of contract conditions (drawn up by Commission lawyers to satisfy the laws of 12 countries); the uncertain timing of calls for proposals (offering grants in specific areas); and the delays in processing and deciding to support particular proposals.

Announcements are made in the *Official Journal* of the European Communities ("which of course you all read"), but also through national Community offices, through government departments and by advertisements in journals. But one recipient of a grant says that the academic grapevine is the best means of communication.

There were a few tips for applicants last week. Nobody in paper-submerged Brussels has time to read 100-page theses, but the brief one-and-a-half page synopsis that applicants are asked to supply is critical, the sole basis for the first weeding out. Because referees may not be fluent in the language in which the synopsis is written, it must be exceptionally clear, but to the Commission it is now also essential that applications involve a collaboration among institutions from two different countries, preferably of different types (for example university and industry).

But having too many partners is impractical, listeners were advised; the usual range is three to five. Applicants, like the good examinees they no doubt often berate for the same fault, must also answer the questions on the form. "It is amazing how many people leave questions unanswered or answer them indirectly", Hurst said. Applications in non-nuclear energy are most likely to succeed (one in three accepted), followed by environment (one in four) and industrial technology (one in six). Biotechnology is at the bottom of the list, with a high demand and a low budget (only one in seven proposals in this field have been accepted).

The British Cabinet Office is preparing a booklet to assist potential applicants. According to a Cabinet Office spokesman, it is "no secret" that Britain was unhappy with the framework programme as presented to ministers earlier this year. The original documentation and legal instruments had not been a satisfactory basis for discussion, he said, though improvements are now hand. The central issue seems to be the British government's wish to apply to the Commission's proposals the disciplines it applies to its own expenditure, he said.

Robert Walgate

• The commission's presentation has been given at Leeds and Cardiff in the past week and is to be taken to Birmingham (12 November), Belfast (13 November) and Glasgow (15 November).

British research

Postdocs over the hill at thirty?

Prejudice in Britain against older researchers is widespread, dissuading many talented people from embarking on postdoctoral research for fear of being ruthlessly discarded within ten years. This is one conclusion from a study by the Association of Researchers in Medicine and Science (ARMS) based on a survey of applicants for recently advertised postdoctoral fellowships.

ARMS says that its survey reveals an unjustifiable prejudice in favour of people younger than 33 years. But far from attracting youth, the prejudice has caused an exodus of British talent abroad, or to other forms of research. The advertisers of the positions were generally disappointed with the number and the quality of the applicants.

The survey covered 200 postdoctoral positions, mostly in biology and medicine, advertised in the principal professional journals during three months from December 1985. ARMS says that fewer than 7 per cent of the positions were for longer than three years. The average duration of the posts on offer was 2.5 years and the average age of those appointed 28.3 years.

Most of all, the association is disturbed by the age distribution of the successful candidates. About a quarter were between 29 and 33 years of age, but only 6 per cent were older than 33. In eight cases, employers complained that many applicants were too old — in their thirties.

The association challenges this preference for younger researchers. It claims that postdoctoral scientists in their thirties are as intelligent, hardworking and competent as in their twenties, but with the advantage of greater knowledge and experience. That they should find themselves trapped in so uncertain and precarious a way of life ironically makes the whole research profession unattractive even to the younger people employers say they wish to attract, according to ARMS.

The report of the survey includes an account of the reasons given by advertisers of the posts for the few high-quality applicants. The common theme is that better long-term treatment has attracted more researchers to industry.

One, a biochemist from Leeds, said that "anybody in molecular biology who is any good has gone abroad, into industry or has left academic circles ... it is almost impossible to fill university research posts now". Another biochemist, based in London, was astounded at the poor response. Three years ago, he said, a similar advertisement would have attracted more than 40 good applicants, but none of the 13 applicants for the post advertised this year was suitable, and it had to be re-advertised.

A Dundee physiologist endorses this view. The quality of applicants for short-term posts has fallen because career prospects have dwindled. Financial rewards are poor compared with those in industry, and better prospects await those who emigrate to the United States, Europe and Australia.

Professor Peter Campbell, deputy chairman of ARMS and professor of biochemistry at Middlesex Hospital Medical School, has been trying to persuade those who support research to change their attitudes. Campbell argues that research often depends on teams of individuals with a range of abilities and spanning many disciplines. He thinks it proper that such teams should include both people with considerable originality and those with special techniques acquired over many years. But those of the second kind tend to be discarded by the system. Campbell also blames the salary structure in British universities. Because salaries are related to age, he says, researchers often find themselves priced out of posts in their mid-thirties.

US cancer

Can NCI cut deaths in half?

Washington

CUTTING cancer deaths in half by the year 2000 is an achievable goal, according to the National Cancer Institute (NCI) In a monograph released last week*, NCI lays out its strategy for achieving that goal But its critics worry that the plans may do more to maintain the health of NCI than they will to reduce cancer mortality

Edward Sondik, coeditor of the monograph, says the NCI approach has two primary focuses, reducing smoking and improving treatment In 1985, 462,000 people in the United States died of cancer, and NCI reckons 30 per cent of those deaths are attributable to tobacco By 2000, NCI hopes to reduce cancer mortality attributable to smoking by between 8 and 16 per cent, implying that the number of people who smoke must be reduced to a half within this decade Although the percentage of the US population that smokes has been declining since 1965, the rate of decline would have to double for males and considerably more than double for females for this goal to be achieved

Reduction in mortality through treatment accounts for half the targeted decline Using new communication tools such as the Physician Data Query (PDQ), a computerized information service, NCI hopes modern therapies will be more widely disseminated NCI is also relying on regional cancer treatment centres and cooperating groups of physicians to test and implement new therapeutic regimens But Sondik concedes that more than half of the projected improvements attributable to treatment must come from treatments yet to be proved effective

In addition to smoking and therapy, the NCI report calls for changes in diet as well as more screening programmes for early detection Reducing fat to 30 per cent of total calorie intake and increasing fibre to 20–30 grams per day will yield an estimated 8 per cent reduction in mortality by 2000, according to the NCI report Another 3 per cent reduction in mortality may be expected from wider use of Pap smears for all women over 20 and mammograms for women over 50

But critics feel the NCI figures are overly optimistic John Cairns of the Harvard School of Public Health says NCI cannot justify the expected decreased mortality projected by the report With cancer deaths currently around 450,000 annually, Cairns says NCI projections require that more than 100,000 deaths be prevented annually through treatment Apart from breast cancer, where improved mortality rates have been achieved, saving approximately 10,000 lives annually, Cairns wonders where the other 90,000 or more will come from

A debate is currently raging over whether NCI is winning the war on cancer (see the *News and Views* article by Jared Diamond in *Nature* **323**, 488, 1986) which was officially declared in 1971, Sondik says improved long-term survival rates show that there have been significant strides in treatment for many types of cancer But others argue that age-adjusted mortality statistics paint a less encouraging picture and that a dramatic turnaround will be needed to achieve NCI goals

At the heart of the debate is whether NCI is receiving too large a share of the federal research budget, and whether that share is being spent properly Critics say it has put too great an emphasis on treatment at the expense of prevention, but Sondik counters that prevention efforts currently account for about 28 per cent of NCI outlays Treatment programmes have been receiving approximately 30 per cent of the NCI budget

What cannot be gainsaid is that the NCI budget is large, and growing In 1987 NCI will receive approximately $1,400 million, slightly less that one quarter of the total budget for the National Institutes of Health NCI is seeking $1,700 million for 1988 But its associate director Peter Fischinger is not sure the fight against cancer will cost much more in the future He hopes that the mix of prevention, screening and treatment will achieve the desired results

NCI's goal of halving cancer mortality by 2000 is not new, having been first announced in April 1984 at a congressional hearing NCI has steadfastly maintained that dramatic reductions in cancer deaths are possible But officials now sound a note of caution Fischinger says the goals for 2000 are not testaments, only estimates It will be up to Congress to decide whether those estimates are worth the hefty price tag **Joseph Palca**

French research

Teetering on the brink

YOUNG French scientists who were offered jobs for life earlier this year by the leading French research council, the Centre National de la Recherche Scientifique (CNRS), but have since been denied this privilege, are taking their case to law

The 522 people concerned were appointed by the usual procedures in the annual recruitment to the research council, but then were effectively dismissed by a government decree invalidating the appointing committees The group accordingly formed a pressure group, the "Collectif des Admissibles", and appointed a lawyer to argue its case Legal proceedings have now begun, in the highest court of the land, the Conseil d'État, against science minister Alain Devaquet, who issued the decree, and (in a lower court) against the director-general of the research council, Serge Feneuille

Members of the group are also seeking substantial damages in private actions for loss of livelihood, expenses in relocation and other inconveniences Meanwhile, the research council has offered one-year contracts to 285 of the 522

The background is complex and political The Conseil d'État ruled on 12 May that certain elections to the appointments committees of the research council had been irregular In the event, the necessary corrections could have been made when the committees were re-elected for 1987 But the arrival of the new government and, it is said, pressure from right-wing physicians discontented with the survival of CNRS is thought to have persuaded the government to take the ruling seriously Devaquet's decision to dissolve the CNRS appointments committees and to annul all appointments made this year seems not to have been strictly necessary in the wake of the Conseil d'État's ruling That is the interpretation that many French scientists are putting on the affair

But what effect will it have on French science? A new Comité National (the body of appointments committees) is to be elected next year Feneuille, who comes from industry, is said to want to make the stopgap short-term contracts a permanent feature of CNRS life

Next year's Comité National will have to consider which of the 285 short-term appointees from the original 522 'admissibles' should stay, there is no guarantee that all will Those thinking of joining the research council are also in a quandary will the 285 have priority, affecting the numbers of new staff to be appointed?

For the longer term, French researchers are having to come to terms with lower recruitment rates than previously expected, as well as lower budgets They will also be facing a new Comité National, which, under a new constitution, will include representatives from the whole of the university teaching community, and not just from researchers as at present In the harder sciences, where about 60 per cent of university staff are in research and in some way connected with the research council, the effects of this change may not be too great But in medicine, where only 30 per cent do research, the new powers in control at CNRS may be evident

Robert Walgate

A cosmic rod in pickle

SIR—Under this title, Hoyle and Wickramasinghe[1] have tried to defend their various positions, and the claim that their earlier predictions had "wilfully and even maliciously been overlooked"

It seems clear, however, that the real reason that their work is not widely accepted or referred to is not that they have "sinned mortally" by making a "contact between biology and astronomy", but because so many of their various claims, put forward with so much certainty on the basis of unimpressive and even inaccurate evidence, have routinely been abandoned by themselves or proved wrong by others (see refs 2 and 3) Indeed, even before publication, their *Nature* article had been rendered obsolete by a published paper[4] they had submitted on 29 November 1985, but did not refer to This paper claimed hollow, spherical C_{60} (buckminsterfullerene) molecules[5] as the explanation of the composition and ultraviolet (UV) spectrum of interstellar grains that had been earlier identified, *inter alia*, as dried hollow bacteria[6,7] If the absorbence in the infrared (IR) were really due to such bacteria the absorbence in the UV would be far greater than in the IR[8,9] They cannot have it both ways, especially as the UV and IR spectra of this C_{60} molecule have not yet been measured (R F Curl, personal communication)

But there are other problems As it was part of their Fig 1, Karim, Hoyle and Wickramasinghe had to have known that the rest of the absorption spectrum of tryptophan did not fit the curves in their Figs 3 and 5 when they claimed that "the discovery of a broad interstellar absorption feature centred on the λ 2,800Å in the extinction curve of starlight confirms the presence of proteinaceous material in grains"[10] In ref 12, they must have deliberately cut off the low wavelength part of their own (mislabelled) curve in Fig 1 to make it fit the curves in Fig 4 to support one of their many now abandoned theories (For further comment, see refs 2–4, 8 and 11) Also, Hoyle *et al* [6] knew that my colleagues and I[2] had never claimed the existence of a peak for *Escherichia coli* at 220 nm, and so on This type of scientific behaviour is clearly unacceptable

In the past few years, many comments on their publications have appeared For example, Greenberg[13], McLachlan and Nandy[14,15] and Savage and Sitko[16] have shown that the claimed[10] absorption feature at λ = 2,800Å was produced by saturation effects in overexposed spectra and was flagged as such in the data bank

Thus, the long history of unwarranted claims by Hoyle and Wickramasinghe means that I, and many other scientists, will not accept anything they claim, be it about darwinism, viruses, bacteria, *Archaeopteryx*, or even interstellar grains or steady-state cosmology, unless and until it is demonstrated by others with far better batting averages and about whose works it cannot be said "That's not cricket" By the way, astronomers and chemists, also, have "rods in pickle"* for them too

Indian collaboration

SIR—The news item "Indian science Foreign software giants pounce" (*Nature* **323,** 102, 1986) states "Astra's subsidiary in Bangalore has taken the cream of Indian biochemists, including the chief biotechnologist of the Indian Institute of Science" As I am a biochemist who has acquired the label "biotechnologist" and am intimately involved in the organization of the Astra centre, I wish to say that the statement is not correct I am not on the payroll of Astra nor have any of my colleagues left the institute to join Astra The core group at the centre consists of fresh PhDs who were ready to leave the country and take up postdoctoral fellowships in the United States Besides, Astra is trying to bring back qualified Indians from abroad, so the centre is helping to prevent a brain-drain, both internal and external

Astra has given funds to the Indian Institute of Science, enabling me to further my basic research, which I have been carrying out for several years At the same time, we have an opportunity to interact with the centre on problems related to the alleviation of human suffering The Astra centre seems to us to be a unique, open and fair collaboration between an academic and an industrial research institution The Astra centre in Bangalore is not a subsidiary of Astra Sweden The centre will develop its own know-how and is recognized by the government as a non-profit research organization It is registered as a society in Karnataka State The government of India has laid down conditions to protect the Indian interests in terms of publications, patents, royalties and the conduct of research

There is much talk about the virtues of collaboration between industry and academic research There is also criticism that scientists in India have not been doing relevant research and that they should have discovered cures for tropical diseases a long time ago Now that scientists are trying out a new model of collaboration and when the government has done what it can to protect Indian interests, it is a pity to lump together and to condemn all multinational efforts I wish K S Jayaraman had made a deeper study of this collaboration model before offering his comments or those of his critics, which could harm not only the institution but the entire philosophy

Faraway quasars

SIR—You quote me (*Nature* **323,** 193, 1986) as saying that it is only a matter of time before very long baseline interferometry yields the absolute distances to at least one quasar with an interposing gravitational lens Alas, were that only true What I said, in fact, was that we know of no way to determine directly the distances to quasars But if a gravitational lens between the quasar and us forms multiple images, then, if the quasar cooperates, for example by changing its luminosity sharply, it is possible, at least in principle, to determine the *differences* in the times taken by light to propagate from the quasar to us along the paths for the different images I stated my opinion that it would just be a matter of time before an imaged quasar cooperated sufficiently for us to determine such time differences

Physicists about to hi-jack DNA?

Unless molecular biologists are careful and energetic, they will find that the mechanical and thermodynamic properties of DNA have been taken over by physicists.

MOLECULAR biologists, if pressed, will readily agree that more should be done to throw light on the properties of naturally occurring macromolecules in the molecular environment in which they ordinarily exercise their biological activity, usually that of water. More than that, much is being done, experimentally and otherwise. X-ray diffraction measurements of, say, crystalline proteins are not always the abstract studies they may seem, given the large water content of many specimens. The application of nuclear magnetic resonance techniques to enzyme molecules may indirectly say much about water interactions. The abiding obstacle, in these connections and others, is that the important molecules are so often complicated in their own right, even without the extra complication of their external interactions. People sigh for simpler systems.

That is where physics may have the edge. There is probably a great deal in the opinion that biologists are reconciled to having to tackle the problems with which nature confronts them, but that physicists are free to pick and choose, tackling only the problems they can reasonably hope to solve. Put starkly, like that, the distinction is obviously a simplification (Sir Peter Medawar's *The Art of the Soluble* is, in any case, a biologist's book.) But the caricature does seem to illustrate a difference of style, which is in turn nicely illustrated by a neat analysis of the properties of DNA molecules in solution by L. L. Van Zandt of Purdue University appearing in *Physical Review Letters* (**57**, 2085, 1986).

The starting point for Van Zandt's analysis is an account which appeared two years ago (Edwards, G. S., Davis, C. C., Saffer, J. D. & Swicord, M. L. *Phys. Rev. Lett.* **53**, 1284, 1984) of the absorption of microwaves in solutions of DNA. Part of the motivation of that work was the belief that measurements might throw light on suggestions that microwave absorption can cause biological damage even when the amounts of energy involved are very small, perhaps because of some resonance between the microwave frequency and a vibrational frequency of some vital and susceptible molecule.

But how could such a molecule, say a DNA molecule, even if characterized by well-defined frequencies of vibration, accumulate substantial amounts of energy in these vibrational modes while surrounded by water molecules whose effect would be that vibrations of any kind would be efficiently damped? Edwards and his colleagues were sustained by their earlier observation of a dramatic increase in the gross absorption of microwaves by solutions of DNA from *Escherichia coli* in the presence of the endonuclease DNase I. They inferred that the continuing degradation of long molecules would assure a constant supply of shorter molecules capable of vibrating resonantly with external microwaves.

So why not test this possibility by using the techniques of genetic manipulation to make pieces of DNA whose size is well defined? Edwards and colleagues did just this and made two remarkable discoveries. First, well-defined DNA molecules, whether circular or linear, do indeed show resonance absorption of microwaves in the frequency range from 1 to 10 GHz. Second, the absorption peaks are surprisingly sharp, suggesting ineffective damping by the surrounding medium.

Why that should be is for Van Zandt to say, but the numbers are interesting in themselves. The measured damping implies that the relaxation time, that needed for a vibrational impulse to be dissipated, is of the order of 300 picoseconds. But the velocity of sound in DNA is within 15 per cent of 2 km s^{-1}. One consequence is that vibrational excitations can travel only about 1,500 base pairs along a linear DNA molecule before being dissipated, which in turn implies that coherent vibrations over much greater distances will not easily happen. That is why Edwards *et al.* found that their resonance frequencies were usually harmonics of a fundamental.

Van Zandt has had the benefit of an even more striking demonstration of anomalous resonance in DNA (by the Edwards group) based on measurements of DNA molecules with 5,480 base pairs derived from a circular plasmid in which supercoiling has been relieved by the use of a topoisomerase. The remarkable feature of the measurements is that the strength of the absorption (four peaks between 3 and 9 GHz) increases with increasing frequency, the opposite of that expected of an efficiently damped system.

The explanation can be made simple enough to suit any physicist. First, the vibrations responsible for the resonances are simple organ-pipe vibrations — standing compressional waves set up around the circular channels of the plasmids. A few simple properties of the solvent, water, are relevant. Energy dissipation in pure water arises because of the stretching and distortion of hydrogen bonds, but because these form and reform in times of the order of 10^{-11} seconds, they should be measurable only at frequencies of 50 GHz and above. Van Zandt's question is how circular DNA can so profoundly modify this behaviour.

The molecular model is simple. Suppose that there is a single layer of water molecules more tightly bound to the DNA than to the bulk of the solvent, so that it will move with the molecule if that should vibrate, but at the same time be better adapted than DNA to sense and be influenced by the molecular motions in bulk liquid. Van Zandt constructs the crudest of all possible mechanical models to represent this state of affairs. Take two masses, one representing the mass of DNA (per unit length) and the other the mass of the bound water layer (again per unit length) and imagine them connected by an elastic spring. Let the second mass (the bound layer of water molecules) be damped, and calculate the absorption of the system as a function of microwave frequency.

Sceptics will say that even this simple system has enough adjustable constants to fit pretty well any measured curve. Van Zandt plays fair by using real values (the mass of DNA and the bulk viscosity of water) to fit as many of them as possible. Even the allowable frequencies of vibration are taken from measured velocities of sound in dry DNA (and the condition that there must be an integral number of wavelengths around a single circle of DNA). The result is a remarkably good fit of the position of the four absorption peaks, but the measured peaks are much broader than predicted.

Where this will lead is anybody's guess. Van Zandt promises a more detailed account of the structure of the solvent. The discrepancy between the width of the measured and predicted peaks cannot be made to go away by adjusting (and increasing) the damping constants in the model, for that has the effect of changing the relative strength of the peaks. Van Zandt thinks that even a circular plasmid whose supercoiling has been relieved may have some residual tertiary structure, but there are others who will see the difference as an opportunity to learn more about the solvent interactions. How soon will it be before molecular biology laboratories equip themselves with a klystron and some waveguide?

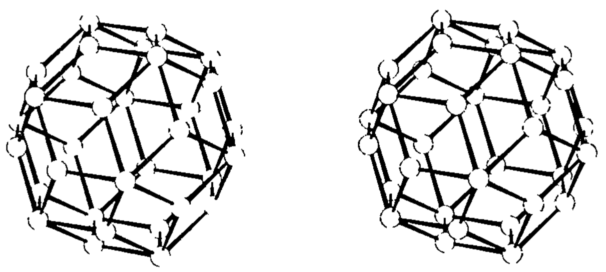
John Maddox

Five-fold symmetry

Millimetre-sized quasicrystals grown from aluminium alloy

Kevin Knowles

QUASICRYSTALS, materials with 'forbidden' five-fold symmetry, were discovered two years ago, but their investigation has been dogged by the lack of large crystals. The critical X-ray and electron diffraction data which demonstrate five-fold symmetry are from very small quasicrystal particles, complicating interpretation of diffraction intensities which so far do not seem to be consistent with any clear atomic arrangement. But investigations should take a leap forward with the report of Dubost *et al* on page 48 of this issue[1], which describes the growing of quasicrystals approaching a millimetre across, and raises the real prospect that clear X-ray and neutron diffraction pictures of single quasicrystals will now be possible.



Rhombic triacontahedron, arranged as a stero pair for a three-dimensional view (courtesy of A. Mackay, University of London)

One of the basic principles of morphological crystallography is that the external shapes of crystals are determined by the point-group symmetry of the underlying fundamental units of the material, the unit cells, which are typically of nanometre dimensions. Thus most scientists in their schooldays will have grown crystals of alum from solution and will have found that although some will crystallize in regular octahedra characteristic of the underlying cubic symmetry, most look irregular, but nevertheless can be described in terms of simple arrangements of the unit cell.

The quasicrystals of Dubost *et al* are grains of an Al–Li–Cu alloy showing triacontahedral morphology. They are 'quasicrystalline' in the sense that their morphology alone would imply an underlying 532 or m$\bar{3}\bar{5}$ point-group symmetry, incompatible with translational symmetry inherent in the perfect crystalline state. The grains grew from the 'T2' phase of Al–Li–Cu, one of the family of icosahedral phases whose structure and properties have been of intense experimental and theoretical interest since the initial reports of these phases in alloys of Al–Mn, Al–Fe and Al–Cr[2-4].

The T2 phase is not only of academic interest — it occurs as a stable grain boundary precipitate in commercial Al–Li–Cu–X alloys such as those now being developed by aluminium manufacturers for light aerospace materials with consequent savings in fuel bills. The dimensions of the Al–Li–Cu T2 grains grown by Dubost *et al* under conditions of very slow cooling, allowing only a few nuclei to grow, contrast with the precipitates of micrometre or sub-micrometre dimensions produced from other icosahedral phases, for which the cooling rates needed to produce the phases are typically of the order of 10^7 K s^{-1}, similar to the fastest quench rates reported for obtaining crystalline phases, but far slower than quench rates for metallic glass formation. Indeed, these T2 grains are sufficiently large to produce X-ray and neutron diffraction patterns from single crystals. The results from such experiments are keenly awaited, as the size of quasicrystals produced to date has allowed only powder X-ray diffraction data to be obtained.

These results should help to determine the origin of the line broadening in powder X-ray diffraction patterns that can be interpreted as evidence of either frozen-in phason strain or random icosahedral packing[5,6]. (The simplest way to see a phason in quasicrystalline materials is as a local violation in the matching rules in a Penrose tiling[7], switching, for example, the internal vertices of rhombic triacontahedral units within the tiling.)

The ability to produce large grains of icosahedral phase will also be important for other electron-beam work, which indicates that the chemical composition of icosahedral phases grown under rapid cooling conditions is inhomogeneous on a 5–10-nm scale. Chen *et al*[8] have reported changes in the concentration of Mn in Al–Mn icosahedral phase from place to place, and dark-field transmission electron microscopy reveals cloudy and speckly contrast that can vary as a function of diffraction vector, beam direction and alloy formation[9-14].

This work implies that structural features analogous to spinodal decomposion or anti-phase domain boundaries in crystalline materials are inherent in rapidly solidified icosahedral phases. Will this also be found to be the case in the large T2 Al–Li–Cu grains where presumably equilibrium is more easily reached?

The mechanical properties of this phase are particularly relevant. Theoretical considerations by Lubensky *et al*[15] on the basis of hydrodynamic arguments predict that quasicrystals are inherently extremely brittle as dislocation motion is virtually inhibited by the slowness of phason modes in these materials.

On this basis, Lubensky *et al* suggested that it would be virtually impossible to fabricate and manufacture macroscopic quasicrystals (such as the ones grown by Dubost *et al*), although they recognized that the dynamics of dislocation motion in quasicrystals would alter radically if the phason modes were rendered non-hydrodynamic. It is therefore of interest to discover whether the T2 phase is indeed extremely brittle or whether it is instead merely similar to other intermetallic phases, which in general are characterized by high hardness and limited ductility. Dislocations, if they exist in icosahedral materials, must, on the basis of current electron microscope evidence, be either extremely rare or otherwise not exhibit the characteristic strainfield contrast seen in crystalline materials.

It seems clear that the report of Dubost *et al* will stimulate more work on icosahedral materials, particularly on the thermal stability and energetics of the phase formation in Al–Li–Cu. We can only imagine where our understanding of icosahedral materials would be if more than 30 years ago Hardy and Silcock[16], the original discovers of the T2 phase, had had an electron microscope and had been able to obtain similar icosahedral electron-diffraction patterns to those found by Shechtman *et al*[2] in Al–Mn. ☐

Molecular biology

Manipulation just off target

R Michael Liskay

PROGRESS has been made in several laboratories towards gene targeting — recombinational interactions between an introduced DNA molecule and its homologous sequence residing in a chromosome — in mammalian cell systems[1-4] The targeting studies of Thomas and Capecchi reported on page 34 of this issue[5] are provocative in several respects They indicate that DNA introduced into the nucleus by microinjection can induce mutations at high frequency in the target gene in a totally unexpected manner The observations both sound a note of caution for some applications of gene targeting and provide new methodologies that could facilitate the efficient introduction of mutations into a particular region of a gene

High-efficiency targeting is a potentially powerful approach for manipulating the genomes of higher organisms in a manner analogous to the molecular gymnastics that are possible in yeast, including the creation or removal of mutations in any chromosomal sequence for which one possesses a molecular clone

Thomas and Capecchi derived recipient mouse cell lines containing a mutated *neo* gene whose normal activity confers resistance to the toxic compound G418 This particular mutant form of the gene, here called the resident gene, is an 'amber' mutation that causes premature termination of translation and a resultant truncated protein The amber mutation (a single base-pair change) is located in the initial portion of the coding region of *neo* and its presence can easily be detected by molecular techniques Thomas and Capecchi attempted to correct the resident *neo* gene by microinjecting a different mutant form of this gene, a deletion that removes the last 52 amino acids from the protein, directly into the nucleus of the recipient cell At a frequency of approximately 1 per 1,000 injections they recovered cells resistant to G418 Roughly half of these lines now contained, as expected, an apparently normal *neo* gene — that is, the amber mutation had been removed Surprisingly, in the rest of the G418^r cells the amber mutation was maintained Eight of these exceptional, corrected genes, each representing an independent occurrence, were cloned into bacteria and their nucleotide sequences near the amber mutation were determined Each gene now harboured a compensating mutation Three different insertion mutations were found insertion of G, of T or of GGCT These insertions now allow a normally silent and out-of-phase protein synthesis start signal to be used A functional protein is produced that is incorrect for the first few amino acids but normal for the rest Furthermore, the mutations occurred within the first of two directly repeated sequences (GGCTAT) That each insertion results in a tandem duplication of at least a portion of the repeat sequence leads the authors to conclude that direct repeats are a prerequisite for this phenomenon

Control experiments, including microinjection of either the same amber mutant of *neo* or an unrelated DNA molecule, did not yield any G418^r cells From these control injections the authors conclude that the process requires both homology and at least one nucleotide difference, or mismatch, between the interacting genes Because of this apparent requirement for a mismatch, Thomas and Capecchi invoke the formation of heteroduplex DNA between the resident gene and the incoming plasmid molecule as an intermediate and therefore refer to this newly observed process as heteroduplex-induced mutagenesis They point out that because restoration of a functional gene was intrinsic to their experiments, many (even most) of the mutations induced by these interactions would be undetectable, making the actual frequency of mutations much higher than the 1 in 1,000 seen

Thomas and Capecchi also analyse how the compensating mutations result in functional protein These experiments provide a glimpse at how the ribosome can apparently reinitiate protein-chain elongation after encountering a single stop signal, provided there exists another start signal in the immediate vicinity

The main issue, however, is the impact that these findings have on various applications of and strategies for gene targeting in mammalian cells One might first ask why others studying targeting in mammalian cells have not observed error-prone events The answers seem to be relatively simple In one recent study[2] direct selection for targeted integration was not applied and there was no reason to examine the targeted gene at the nucleotide level In other experiments involving direct selection in a manner similar to that of Thomas and Capecchi, the nature and/or positions of the mutation in the resident sequence were such that the detection of error-prone events would often be precluded[1,3,4] For example, extensive terminal or internal deletions of the resident gene would not be prone to correction by the proposed mutagenic mechanism Note that in the bacterium *Salmonella* there exists a possibly related phenomenon termed selfing whereby one mutation can be rescued by the very same mutant DNA[6] Unfortunately, these events have not to my knowledge been analysed at the molecular level On the other hand, gene conversion, a form of nonreciprocal recombination, has been shown to act with fidelity in the several cases examined in fungi[7-9]

There are two general implications of heteroduplex-induced mutagenesis First, the results provide a caution to those who wish to manipulate mammalian genomes by gene targeting It is possible that unpredicatable and unwanted mutations could be introduced into a gene intended to be the target for correction For gene therapy in humans these potential side effects should be considered serious Second, and more positive, Thomas and Capecchi's observations suggest new methods for directly mutating mammalian chromosomal sequences that differ from the approaches that are standard fare in the yeast *Saccharomyces cerevisiae* In this yeast, specific mutations are engineered into a cloned sequence one-by-one and used to replace one-by-one the normal sequence by a targeted interaction Based on heteroduplex-induced mutagenesis, a single appropriately constructed plasmid might prove sufficient to induce a library of mutations in a particular region of the gene This approach might be used to advantage for mutating the control region (for example, promoter) of genes to define the location and function of *cis*-acting regulatory sequences Such regions frequently contain repeated sequence elements and therefore should be prime targets for the proposed mutagenesis by incoming DNA

One obstacle preventing the widespread use of targeting procedures is the propensity of mammalian cells to incorporate DNA into the genome in an essentially random fashion The efficiency of homologous relative to nonhomologous interactions is presently being achieved at a ratio of about 1 to 100 This ratio must be improved before the mammalian genome becomes as amenable to genetic tinkering as its smaller cousin, the yeast □

Elementary particles

Colour theory in a spin

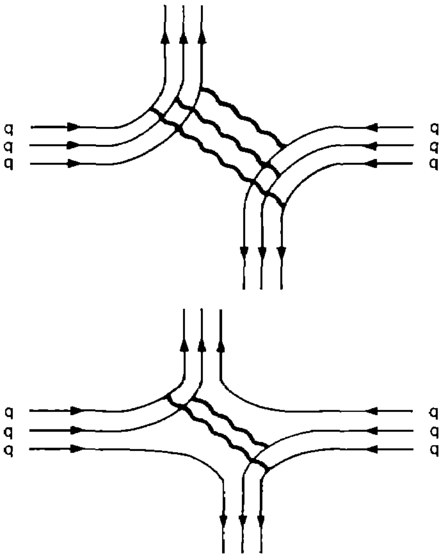
Harry J Lipkin

EXPERIMENTS in which beams of high-energy polarized particles are scattered by polarized protons[1-5] continue to puzzle, confuse and cause controversies among high-energy physicists. New experiments show a strong dependence of the scattering processes on the directions of the proton spins, which is not simply explained by accepted theoretical models based on quantum chromodynamics (QCD). The original establishment view was that little could be learned from polarization experiments because theory predicted no spin dependence at high energies. Subsequent investigations with QCD predicted some spin dependence, but not enough to explain the experiments. Thus some experimenters claim that they violate the predictions of QCD. The most recent experiment[1] suggests that this strong dependence suddenly disappears mysteriously at a higher energy. This causes even more confusion.

Spin physics was originally considered trivial at high energies, because of helicity conservation[6,7]. Particles with spins, such as electrons, neutrons, protons and quarks, are called right-handed or left-handed, respectively, if their spins are oriented parallel or antiparallel to their direction of motion. QCD predicts that this handedness (called helicity) is conserved at high energy, that is, it does not change in collisions at high energy, although it may do so at low. Thus, QCD seems to predict that protons emerge from any collision with their original helicity, and that no further useful information can be obtained from any spin measurements.

The argument that helicity conservation makes spin physics trivial is strictly valid only for elementary spinning particles. In the 1950s physicists believed that protons and neutrons were elementary particles and that Yukawa's meson theory of nuclear forces explained nuclear structure and the forces holding nuclei together, just as quantum electrodynamics (QED) explained atomic structure and the forces binding atoms together. Soon many new particles, now called hadrons, were discovered and it became clear that none was elementary. We now believe hadrons are built from smaller building blocks called quarks, bound together by QCD forces. The proton is no longer elementary but contains several quarks spinning in opposite directions. Quarks with opposite helicities can be exchanged between the two protons, thus changing the proton helicities even if the helicity of each quark is unchanged. Spin measurements therefore enable us to explore the internal helicity structure of the proton.

Spin effects played a crucial role at a very early stage[6-8] in providing experimental tests of the quark structure of hadrons. Already in 1945 the anomalous magnetic moment of the proton was interpreted as evidence that the proton was not an elementary particle like the electron, satisfying the Dirac equation. The quark model gave the first satisfactory explanation of the magnetic moments of the proton and neutron, by having these particles made from two kinds or 'flavours' of quarks, now called up and down, with electric charges +2/3 and −1/3 of the proton charge, respectively. The proton is made of two up quarks and one down quark, the neutron of two downs and one up, thus giving the observed charges of +1 and 0. Because all quarks have the same spin as the proton, the right total spin for the proton and neutron is obtained by having the up and down quarks spin in opposite directions, giving a total spin which is the difference between the up and down quark spins. But quarks with opposite electric charges spinning in opposite directions have their magnetic moments all pointing in the same direction and add up to a large value. This explains why the proton with a positive charge has a magnetic moment roughly three times the Dirac value and the neutron with no charge has a magnetic moment corresponding to roughly double the Dirac value for a particle with negative charge. A quantitative calculation of the ratio of the proton and neutron moments with this picture gives the value −3/2, in remarkable agreement with experimental results.



Two protons, each consisting of three quarks (q) collide at high energy and are scattered through a right angle. Top, direct scattering three high-energy gluon exchanges (wavy lines) between quarks in the two protons cause the deflection. Bottom, exchange scattering in each proton, internal motions have already produced a quark moving in the final direction, and only two high-energy gluon exchanges are required. The amplitudes of these diagrams are added to calculate the probability of the whole process.

The first excited states of the neutron and proton, now called Δ, had a spin three times the spin of the proton. These are now described as being made of the same three quarks with all spins parallel. There were also new companions of these particles, originally called strange particles. The greek letters Λ, Σ and Ξ denote the different strange particles with the same spin as the proton, an asterisk is added to denote the excited states. These are now believed to contain one or more quarks of a third flavour called strange quarks. In 1966 Federman, Rubinstein and Talmi[9], and independently Sakharov and Zeldovich[10,11], calculated the excitation energies of the parallel-spin states using an extremely simple model of the spin-dependent forces based on the analogy with hyperfine interactions in atomic physics. These authors obtained relations between the masses which were in excel-lent agreement with experiment, for example

$$\Delta - \text{proton} = (1/2)\,(2\Sigma^{*}+\Sigma-3\Lambda)$$

The experimental values of the two sides of this equation are 307 and 294 MeV, thus supporting the assumption that the spin forces between quarks are like the hyperfine interactions in atoms.

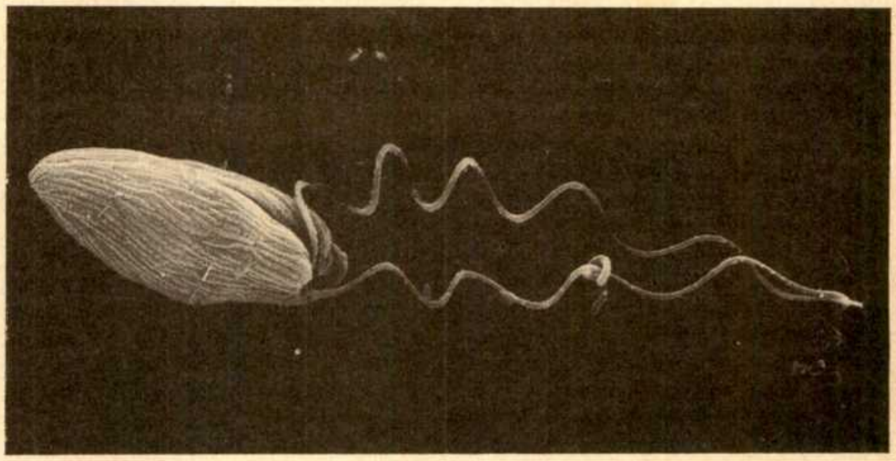
There is now an entire family of hadrons called baryons, all, like the proton and neutron, made from three quarks. There is also another family of hadrons called mesons, made of a quark and its antiparticle the antiquark. These include the pion (π) which has the two spins antiparallel, its strange partner the kaon (K) and their lowest excited states, denoted by ρ, ω and K*, with their spins parallel. Sakharov and Zeldovich[10,11] used their assumed hyperfine interactions to obtain a remarkable relation between meson and baryon masses

$$\Lambda - \text{proton} = (3/4)(K^{*}-\rho) + (1/4)(K-\pi)$$

The experimental values of the two sides are 177 and 180 MeV, giving striking support to the assumption that mesons and baryons are made of the same quarks.

There are many more examples of how spin effects have helped to reveal crucial clues to hadron structure which eventually led to QCD. I will now consider the attempts to understand spin effects in proton–proton scattering at high energies.

Perhaps some future article will begin "Back in the 1980s physicists believed that quarks were elementary particles and that QCD explained hadron structure and the



THIS unusual microorganism was recently found by Mr Harry Burton and Dr Ian Bayly in the course of an Australian Antarctic Division examination of a meromictic lake. These lakes have two well-defined liquid layers below the ice overlay; the top layer has a high oxygen content and low salinity, the lower layer has no oxygen but does have high concentrations of ammonia and hydrogen sulphide. The boundary between the layers is called the chemocline. The microorganism — currently known as Eric — is found only in the 30 cm of water directly below the chemoline. To go with this habitat, it has an unusual lifestyle; its outer surface is covered with bacteria, which appear to cling together with 'wing-like' structures. The bacteria have not been found separately. The little that is known about Eric is reported in *Science News, Fiji;* the Australian team are at present trying to breed from him.

Rebecca Ward

---

forces binding quarks together". These speculations that even quarks and leptons may be composite systems can be avoided by assuming that all hadron structure physics is described by QCD just as all condensed matter physics is described by QED. But no one knows how to calculate the properties of a type II superconductor from first principles with QED; similarly there is no clear recipe for the application of QCD to the description of hadron structure and the prediction of experimental results. In both cases the systems and the dynamical equations are too complicated. Theorists use QCD hand-waving arguments to pick a principal or 'leading' contribution for calculating experimental predictions. If a prediction agrees with experiment, they are happy and write a paper. If it disagrees with experiment, they write a paper anyway, and blame the disagreement on nonleading effects. If there are no experimental results available, they publish their result as a QCD prediction. If subsequent experiments disagree with this prediction, experimenters often claim that their results disagree with QCD, rather than with a particular choice of a leading term.

Experiments in the 1970s which scattered high-energy electrons from protons showed that at high momentum transfers the proton behaves like an assembly of free quarks with very weak interactions, even though the interactions between quarks are very strong at low energies. The fact that these interactions become much weaker at high energies has been given the name asymptotic freedom and shown to be predicted by QCD. QCD arguments suggest that experiments at sufficiently high energies can be treated with the use of the leading terms in an expansion called perturbative QCD, because the interaction has become weak enough to be treated by the same perturbation techniques used in QED. But no one has a convincing prescription for where high enough energies begin, and there is a running controversy on this point between different groups of theorists.

The recent polarization experiments are not explained by treatments using any of the obvious leading terms. The first experiments showing nontrivial spin effects motivated new calculations of polarization effects based on perturbative QCD suggesting that these experiments can give useful information after all about hadron structure and QCD dynamics. The simplest leading term predicted that the probability for proton–proton scattering by 90° should be twice as large if the spins of the protons in the beam and in the target were parallel than if they were antiparallel[12,13].

Theorists were delighted when new experiments approached just this factor of two[3] and seemed to level off there, but further experiments at higher energies showed a continued increase to factors as large as four[4]. New models arose, all paying lip-service to QCD, but with different leading terms. The latest result[4] further confuses the theorists by giving the same value for the scattering of protons with parallel and antiparallel spins, implying a sudden disappearance of the large difference which had risen to a factor of four at somewhat lower energies. There are also other experiments showing further disagreements with theory. Single-helicity-flip transitions were observed in 28-GeV proton–proton scattering at high transverse momentum[5], whereas the quark-exchange mechanism with helicity conservation at the quark level cannot produce a single helicity flip. An additional unexpected polarization effect was seen when ρ mesons were produced in collisions between pions and protons[14]. Strange particles producted in proton–proton collisions have long been known to be strongly polarized for reasons still not understood.

All these experiments suggest that there are interesting physics in these spin effects that are not understood in the simple leading terms and which may give clues to the underlying hadron structure and QCD dynamics. It is still an open question whether further experiments and analysis can reveal the relevant nonleading effects and lead to a better understanding. At present the only viable approach seems to be to continue the search for new clues in the data and try to find signals in the noise.

The basic physics and the essential complications of applying QCD to high-energy scattering can be seen by considering a colliding beam experiment in which two proton beams collide, one coming from the left and one coming from the right, and two proton detectors look for protons scattered at an angle of 90° with respect to the incident beams, one scattered upward, say, and one scattered downward. Because each proton consists of three quarks, the collision process begins with three quarks coming in from the left and three from the right, and it ends with three quarks going upward and three going downward. A theory based on QCD must explain how these six quarks get the appropriate kicks to turn their directions of motion by 90°.

There are several possible scenarios (see figure). The direct scattering scenario has all three quarks that came in from the left going out upward, and all three quarks that came in from the right going downward, or vice versa. The exchange scenario has two of the quarks that came in from the left going out upward and one going downward, and two of the quarks that came in from the right going downward and one going upward or vice versa. In the direct scenario, each of the three quarks coming from the left must have its momentum turned by 90° by exchanging one or more gluons with quarks coming in from the right. The exchange scenario makes use of the complicated internal motion of the quarks inside each proton. At the instant before the collision, there is a certain probability that this internal motion inside the proton coming in from the left will already have two of the three quarks moving upward and one moving downward, and that the proton coming in from the right will already have two of the three quarks moving downward and one moving upward. In this case it will be natural for the three quarks already moving upward before the collision to combine to make a proton going upward, and similarly for those moving downward.

Perturbative QCD suggests that as the interaction is weak at high momentum transfers, the scenario with the minimum number of high momentum kicks should win. The direct scenario requires high momentum kicks to turn each of the six quarks by 90°; this is very difficult at high energies. In the exchange scenario, the exchanged quarks are already going in nearly the right direction before the collision, the kick required is smaller and the QCD interaction stronger, so it is much easier to turn them around. However, the probability that they are initially moving in nearly the right direction is small. Thus two small factors enter into any theoretical comparison, the small probability of considerably changing the momentum of a quark during the collision and the probability that the quarks may initially have a transverse component of momentum in the proper direction. The QCD theory should be able to calculate both of these small factors. They will depend on the energies of the protons and on the scattering angles, which need not be 90°. The recent polarization experiments indicate that leading-term predictions in perturbative QCD disagree with experiment.

Some theorists attempting to find new non-leading effects have investigated how in the exchange scenario the quarks in a proton acquire the large transverse component of momentum necessary to be going in the right direction before the collision. The leading term in the description of the structure of the proton has all three quarks moving in the same direction. There is a tiny probability that two quarks within the proton can have a single 'hard' collision with a high momentum transfer and come apart with high transverse momenta in opposite directions. But they can also have many 'soft' collisions with smaller momentum transfers which have a much higher probability and build up to high momenta from many successive small momentum transfers. The single hard scattering can be treated by perturbative QCD and conserves helicity. But many soft scatterings cannot be treated by perturbative QCD. Such 'non-perturbative' processes must be treated by non-leading terms and do not necessarily conserve helicity. Some model based on QCD is needed to estimate the importance of these effects, which might explain the single-helicity-flip transitions and other disagreements with perturbative QCD.

Thus, spin effects in high-energy hadron scattering are not trivial. They may shed light on how quarks are bound together by the forces of QCD to make hadrons. The problem of the description of spin effects in hadron scattering by QCD remains a challenge. □

Immunology

Unravelling the control of B cells

Gerry G. B. Klaus

A CENTRAL feature of the humoral immune response is that when quiescent B lymphocytes encounter antigen they become activated, proliferate and differentiate into high-rate antibody-secreting cells. This process requires the participation of helper T lymphocytes and accessory cells such as macrophages. It has become increasingly clear that the helper function of T cells can be explained by their production of growth and differentiation factors that act on B cells. The precise functions of these molecules have, however, remained elusive until recently. Now, the complementary DNA encoding several of these lymphokines has been cloned and the sequences of two more are described in this issue[1,2], so the stage is set to unravel this complex process.

The existence of such factors was deduced about 15 years ago with the demonstration that culture supernatants from antigen or mitogen-stimulated mouse T cells contain factors (T-cell replacing factor(s) — TRF) which enable T-cell-depleted spleen cells to produce specific antibody responses[3]. Subsequently, such conditioned media revealed a bewildering variety of activities, such as activation of B cells from the resting state (B-cell stimulating factors — BSF); promotion of B-cell proliferation (BCGF); and/or differentiation to antibody secretion (BCDF). The development of monoclonal antibodies to individual lymphokines and of cloned T cells which secrete a limited array of factors has finally led to some progress in sorting out these activities. Within the past year, progress has markedly accelerated with the application of recombinant DNA technology.

This era was heralded by the cloning of the complementary DNA for murine BSF-1 (refs 4,5), followed quickly by that for the human homologue[6]. Murine BSF-1 has a relative molecular mass (M_r) of 20,000 (20K) and shows multiple activities; it acts on resting B cells and induces them to enter a transitional activation state characterized by the expression of high levels of antigens encoded by the class II major histocompatibility complex. In combination with antibodies to antigen receptors it stimulates these cells to proliferate. BSF-1 can also act as a rather selective B-cell differentiation factor by promoting the secretion of IgG1 and IgE antibodies by B cells pre-activated with lipopolysaccharide.

A second factor (BCGF-II, $M_r \sim 45K$) was initially recognized as a growth factor for a murine B-cell lymphoma (BCL$_1$)[7]. It has recently been shown to cause both DNA synthesis and antibody secretion (IgM and some IgG) in pre-activated normal mouse B cells[8]. Kinashi *et al.*[1] in this issue describe the cloning of the complementary DNA encoding murine BCGF-II, and show that the product also has TRF activity.

A third molecule is the M_r 20K BCDF, which induces antibody secretion in both Epstein–Barr virus-transformed human B cells and pre-activated normal cells, but has no BCGF activity[9]. The complementary DNA for this molecule has also now been cloned by Hirano *et al.*[2] but the murine homologue of this molecule appears not yet to have been identified. Interestingly, this human BCDF is the only one of these three molecules that so far seems to act only on B cells[9].

In contrast, murine BSF-1 is a growth factor for mast cells, and also for T cells, in a way distinct from interleukin-2 (ref. 10). The human homologue also has T-cell growth factor activity[4]. Murine BCGF-II also acts as an eosinophil differentiation factor (EDF, ref. 11), as does highly purified TRF (C. Sanderson, A. O'Garra and K. Takatsu, unpublished data), so there is little doubt that these three activities are produced by the same molecule. Lack of lineage specificity is common among cytokines. Interleukin-1 and interleukin-3 show diverse biological activities and interleukin-2 promotes B-cell proliferation and/or differentiation to antibody secretion (see ref. 12 for a review).

Not surprisingly, this rapid expansion of knowledge in B-cell factors has caused problems over nomenclature. BSF-1 and BCGF-II deserve to be added to the list of the three interleukins because of their multiple biological activities, and both were contenders for interleukin-4 (refs 4, 5, 11). As complementary DNA for BSF-1 was cloned first, this factor will retain that designation, and BCGF-II/TRF/EDF will presumably become interleukin-5 (as proposed by Kinashi *et al.*[1]). These designations, however, have yet to be officially ratified.

Does our current knowledge about these factors produce a coherent scheme of growth and differentiation control in antigen-stimulated B cells? The answer, unfortunately, is not yet. In murine B lymphocytes it is an attractive idea that resting cells become activated by the synergistic action of antigen plus BSF-1 produced by the cooperating T cell, and then become responsive to BCGF-II later in their cycle. Perhaps the balance between these two factors, in conjunction with unknown microenvironmental influences, will then determine which classes of antibody are secreted by the clonal progeny of a particular B cell, or if these progeny will instead revert to the resting state of memory B cells. It is significant that both BSF-1 and BCGF-II are growth and differentiation factors, suggesting that clonal expansion and maturation are coordinately regulated.

Unfortunately, what we know of human B cells does not fit this scheme. First, the genetic homologue of murine BSF-1 has not yet been shown to activate resting human B cells, but rather stimulates proliferation of pre-activated cells[6]. Second, it is likely that there is yet another type of B-cell growth factor for human cells (distinct from interleukin-2). Finally, the factor described by Kishimoto *et al.*[9] has no growth-promoting activity, suggesting compartmentalization of growth and differention in human B cells.

In conclusion, there still may be too many factors in the arena for comfort. Nevertheless, given the availability of the recombinant molecules, various questions can now readily be answered. For instance, are there functional B-cell subpopulations responsive to different factors? Do mixtures of individual lymphokines produce synergistic effects? The answers should not now take long to emerge. □

Neurobiology

Questions of taste and smell

Gordon M. Shepherd, Thomas V. Getchell and Charlotte M. Mistretta

RECEPTOR mechanisms in olfaction and taste have been tough nuts to crack for traditional methods of biochemistry and electrophysiology. The advent of molecular neurobiology and patch-clamp recordings is therefore most welcome, as was evident at a recent meeting*.

In olfaction, biochemical and molecular biological studies were made much easier by the development of isolated olfactory ciliary preparations containing enriched membrane fractions. Several molecular components localized in the fractions are believed to be associated with sensory transduction. The proposed sequence is initiated by binding of odour molecules (odogens) to membrane glycoproteins, such as gp95 (Chen, Z. & Lancet, D. *Proc. natn. Acad. Sci. U.S.A.* **81**, 1859; 1985), located in the cilia. The odogen–receptor complex is believed to activate the stimulatory GTP-binding protein (G_s) (D. Lancet, The Weizmann Institute). Although they appear to be less abundant, G_i and G_o binding proteins have also been identified in olfactory cilia using monospecific antisera (R.R.H. Anholt, Johns Hopkins University). Their functions may be related to receptor 'inhibition', or to neuromoldulatory effects of compounds such as substance P (J.F. Bouvet, Université Claude Bernard) or luteinsing hormone-releasing hormone (C.R. Wirsig and T.V.G., Wayne State University). G_s-deficient pseudohypoparathyroid patients have impaired olfactory perception compared with individuals with normal G_s activity (H.N. Wright, State University of New York).

Cyclic AMP is believed to be a second messenger that is activated during olfactory transduction and leads to excitation of receptor neurones. The activity of cyclic AMP in the olfacotry cilia preparations is 15 times that in the brain, and is increased substantially by GTP, its analogue GTPγS and forskolin, which indicates that the cyclase is activated by a G protein (P.B. Sklar, Johns Hopkins University). Certain molecules evoking different odour sensations also markedly increase cyclase activity. Others, which evoke putrid or solvent odours, do not stimulate this enzymatic activity. This observation suggests that parallel, non-adenylate cyclase-dependent transduction mechanisms are operable. For example, isolated olfactory ciliary preparations also exhibit increased phosphodiesterase activity when stimulated with L-alanine and GTP (R.C. Bruch and T. Huque, Monell Chemical Senses Center); this suggests that certain odogens stimulate phosphoinositide turnover by a G-protein-dependent mechanism.

A major question is to determine if cyclic AMP directly activates membrane channel proteins associated with the ion conductance changes responsible for the receptor potential, or if the effect is mediated by phosphorylation of specific proteins by phosphokinases in the cilia. Protein kinase C has been identified by phorbol ester binding and monospecific antisera (R.H. Anholt), suggesting that phosphorylation of the ion channels may be associated directly with conductance changes.

Patch-clamp recordings demonstrate that olfactory receptor neurones have interesting passive membrane properties that include high input resistances (2–6 GΩ) and low input capacitances 2.6–5 pF) (S. Firestein and F. Werblin, University of California, Berkeley; N. Suzuki, Hokkaido University). Membrane depolarizations are associated with a rapid inward Na^+ current followed by several outward K^+ currents (V.E. Dionne, University of California, San Diego; S. Firestein and F. Werblin). Near-threshold concentrations of odour molecules delivered by pressure injection elicit a 6-pA generator current that depolarizes the cell by 15 mV. There is a systematic relationship between the concentration of the odogen, the magnitude of the generator current and the number of action potentials initiated (S. Firestein and F. Werblin). These results support previous evidence that there is relatively close coupling between the conductance sites associated with ligand binding and those associated with impulse initiation (L. Masukawa, *J. Neurosci.* **5**, 128; 1985).

The relationship of the intermediate molecular stages of transduction and ion conductance changes has been investigated using G protein and cAMP analogues (D. Trotier and P. MacLeod, Laboratoire de Neurobiologie Sensorielle), which enhance conductive charges, supporting the biochemical evidence for an enzymatic cascade leading to the generator current. Single channel conductances in functionally reconstituted membrane proteins isolated from olfactory cilia incorporated in bilayer lipid membranes are enhanced by odour molecules and cyclic AMP (V. Vodyanoy and I. Vodyanoy, University of California, Irvine).

A protein of relative molecular mass 20,000 in the olfactory mucosa (J. Pevs-

---

**IX Symposium on Olfaction and Taste* and *8th Annual Meeting of the Association for Chemoreception Sciences* Snowmass Village, Colorado, 20–24 July 1986.

ner, Johns Hopkins University) binds several types of odour molecules with micromolar and millimolar affinities, is localized in olfactory glands and is released into the surface mucus when the glands are stimulated pharmacologically. The protein may facilitate diffusion of odour molecules through the mucus to receptor sites, or it may inactivate and clear odorants from the active sites. Odour molecules also stimulate secretion from olfactory glands by a cholinergic sensitive pathway, which may provide another mechanism by which odour molecules are cleared from olfactory receptor neurones (M.L. Getchell, Wayne State University).

Immunocytochemical techniques can help to elucidate the location of antigenic molecules in olfactory receptor neurones, which will help further studies on the coding of odour quality and the developmental sequences in neuronal maturation. A neurone-specific antigen (RB-8) in the rat has been characterized as a membrane-associated protein with a relative molecular mass of 125,000 (J.E. Schwob and D.I. Gottlieb, Washington University). In contrast to other regions of the nervous system, RB-8 stains the receptor neurone population nonhomogeneously: the axons of receptor neurones in the ventro-lateral region of the olfactory epithelium to the olfactory bulb are RB-8 positive, whereas axons from neurones with apparently identical morphology in the dorso-medial region of the olfactory epithelium are RB-8 negative. There is heterogeneity in cytochrome oxidase staining of olfactory receptor neurones during the development of normal and odour-deprived neonatal rat pups (P.E. Pedersen, Yale University). The further use of these two techniques should provide a clearer understanding of first principles of the functional organization of the peripheral olfactory system and its primary projections to the olfactory bulb, particularly as it relates to the coding of odour quality. Finally, monoclonal antibodies have been developed as specific probes to identify the emergence of membrane antigens during the development of olfactory receptor neurones (A.I. Farbman, Northwestern University; P.E. Pedersen). Two antibodies, Neu-5 and Neu-9, first bind on embryonic day 13 and stain the developing olfactory nerve bundles as well as the soma and dendrites. Another antibody, Neu-4, binds on embryonic day 14, the earliest time at which an odour-evoked response can be recorded from the olfactory mucosa. Further studies should lead to identification of specific membrane antigens that occur in associated with the development of odogen- and voltage-gated channels in receptor cell membranes.

In the taste field, there is particular interest in whether Na^+ channels are involved in transduction mechanisms for salt taste sensation, mainly deriving from studies where amiloride at least partially blocks the response to NaCl and LiCl but not to other salts.

Amiloride is now thought to block the sodium taste response completely, in contrast to previous reports of only partial blockade. Taste responses to sodium acetate and sodium bicarbonate are suppressed by 95–100 per cent after amiloride application on the tongue, whereas responses to NaCl and NaBr are suppressed by 65–90 per cent (B.K. Formaker and D.L. Hill, University of Toledo). Responses to NH_4Cl and ammonium acetate are not affected. Bretylium tosylate, an antifibrillary drug that opens amiloride-sensitive Na^+ channels, potentiates the taste of NaCl and LiCl, but has no effect on KCl or $CaCl_2$ when applied to the human tongue. The bretylium potentiation is inhibited by amiloride.

Other questions arise, such as why the monoclonal antibody 5B4 stains some, but not all, of the taste-bud cells in a bud. Could the antibody be binding a receptor protein that is present in cells only at certain stages of the turnover cycle? ☐

Geophysics

New radiocarbon dating system

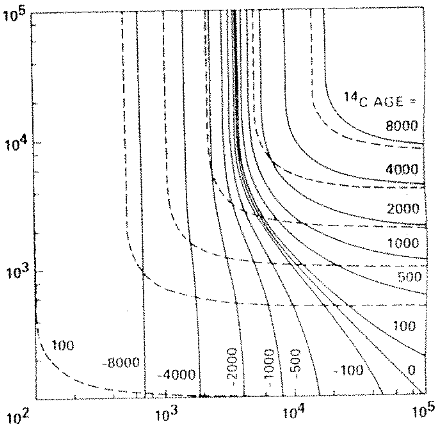
Roy Switsur

THE closest terrestrial analogue to martian conditions probably occurs in the arid valleys of southern Victoria Land, Antarctica; hypotheses suggesting that life exists on Mars are often based on this comparison. The discovery of cryptoendolithic microorganisms that survive in this inhospitable environment without completely adapting to its extremes add to this speculation. Recent studies of these microorganisms by McKay, Long and Friedmann[1] have led to a new approach to radiocarbon dating which is applicable to systems slowly exchanging carbon with the atmosphere, and which relates the true age to the apparent radiocarbon age and to the carbon-exchange rate.

Dry katabatic winds descend from the Antarctic ice plateau to create a lifeless desert where extensive areas of rock lie devoid of all snow or ice cover. The endolithic microorganisms colonize a narrow zone just beneath the surface of the porous granitic translucent rocks. Because of the hostile environment, photosynthesis can occur during only a few hours each year when conditions of moisture and light are suitable. A detailed analysis of this microbial ecosystem suggests that the organisms have very low rates of metabolism and may be very old[2].

The method of dating dead organic matter through its residual radiocarbon content, developed 40 years ago by W.F. Libby[3], is based on a closed system in which the carbon is unchanged through time apart from that lost by radioactive decay. The initial activity is produced through a chain of natural processes: a constant flux of primary cosmic rays impinging on the outer layers of the Earth's atmosphere generate secondary showers with high neutron content. These neutrons lose energy in elastic collisions as they descend until, at a height of about 12 km, they react with stable atmospheric ^{14}N nuclei to produce the radioactive ^{14}C isotope $^{14}N(n,p)^{14}C$.

Following rapid oxidation the radioactive CO_2 is mixed thoroughly, in a very short time compared with the half-life of the ^{14}C, with the existing CO_2 in the lower atmosphere. Most of the radiocarbon enters the oceans and becomes precipitated as a calcium carbonate ooze on the ocean floor. Part of the remainder becomes incorporated into plants through photosynthetic reactions. Of some 80 tons of the ^{14}C isotope that exists on the earth only approximately 3 tons remains in the biospheric reservoir, mainly in the form of photosynthetically produced cellulose. The carbon compounds thus produced by the green leaves of plants form the base of the food net for the animal life of the planet and their natural metabolism results in carbon exchange in equilibrium with the



True age in years (vertical scale) against mixing time-constant in years (horizontal scale). Solid line, with bomb effect; broken line, without bomb effect (from ref. 1.)

atmosphere. The ratio of the radioactive to stable carbon in these living organisms is 10^{-12}, producing a specific activity of about 6.8 picocuries per gram of carbon. On the death of the organism, carbon input ceases and the ratio decreases as the ^{14}C decays with a half-life of 5,730 years. Subsequent measurement of the radiocarbon concentration in the organic material permits the elapsed time since death to be calculated by use of the decay equation as long as there is no contamination by carbon from other sources.

It is well known that the assumption of the constancy of the atmospheric activity is erroneous. Measurements[4] of radiocarbon concentration in samples of growth rings of giant redwood trees of known age show perturbations of 1–2 per cent during the past 1,800 years, and further studies indicate that the natural variation is of the order of 10 per cent. It was realized that a calibration curve is essential for precise radiocarbon ages and much effort has been expended[5,6] in producing this from dendrochronologically dated Douglas firs and oaks.

Atmospheric activity is also affected by anthropological interventions. The cumulative effect of the combustion of fossil fuels (coal and oil) has diluted the activity to an extent estimated[7] to be about 3 per cent, so that wood grown, say, in 1950 would appear to be more than 200 years old. This effect is small compared with that of the intense production of radiocarbon by neutrons generated during the detonation of nuclear weapons in test programmes of the late 1950s and mid 1960s. During this short period atmospheric ^{14}C radioactivity increased by 100 per cent with a peak around 1963–64. The subsequent falling off in activity[8] is crucial to the model of McKay *et al.*

Although this model is applied specifically to the case of radiocarbon, it is capable of wider generalization to other radioisotopes that are diluted by mixing. The basic assumptions are that the carbon leaving the system has the same isotope composition as the total system; that the outward flux of carbon follows first-order reaction kinetics and hence is inversely proportional to the mixing time; and that the ^{14}C is a minute fraction of the total carbon. These assumptions allow a differential equation to be set up for the expression of ^{14}C continuity for a constant volume system and its integration. A further assumption, that the total carbon in the system remains steady over time so that the carbon flux in to the system balances that out, allows the fraction of modern carbon in the system to be estimated. In the absence of perturbations of atmospheric ^{14}C such as those described above, this estimate has a constant value of unity. The nuclear-bomb effect increases this atmospheric ^{14}C content so that the value rises above unity for the period subsequent to the commencement of bomb testing. McKay *et al.*[1] fitted a simple exponential curve to Nydal and Lövseth's monitoring data[8] for the post-1962 decrease in ^{14}C concentration to produce an equation for modern carbon content that does not depend on the true age of the system and may be evaluated for a given calendar date as a function only of the mixing time constant.

The authors also compare the analytical fit with a detailed numerical integration of the bomb radiocarbon measurements for a set of mixing times ranging from 10 to 10,000 years. The larger time-constants give the best agreement. Because the radiocarbon age computation implies a measurement of the ^{14}C content of the system and this is distorted by the temporal variation of modern carbon, the true age differs from the radiocarbon age. It is the value of the mixing time-constant that determines this difference. The figure shows a plot of true age versus mixing time-constant for several values of radiocarbon age, both with and without the bomb effect. The radiocarbon age lies on a locus of points bounded by the true age.

The problems to which the model might be applied require careful consideration but, apart from dating itself, it could possibly be of use for the study of the exchange rates of carbon in geological or biological systems. It might be used for modelling CO_2 in the atmosphere which requires a knowledge of the exchange rate of carbon between the reservoirs of soil and organic materials. Another intriguing possibility is the study of turn over time of carbon in individual living tissues such as bone collagen or brain. □

Archaeology

The environmentalist myth

Jared M. Diamond

MANY anthropologists and archaeologists believe that pre-industrial civilizations did far less damage to their environment than do their modern industrial counterparts. Derived from Rousseau's romanticized concept of the 'noble savage', this view holds that hunter-gatherers and neolithic agriculturists feel a reverence for nature, live in harmony with their environment, practise a conservation ethic and avoid the short-sighted destructive exploitation rampant in industrial societies. What reality does this postulated golden age of environmentalism possess? New evidence[1] adds support to the view that the golden age is a myth.

Recent archaeological discoveries have destroyed the assumption that Eden's hunters were conservationists. On every oceanic island for which we have adequate knowlege, the first arrival of humans was quickly followed by the extermination of all or most large animals, the best-known victims being the moas of New Zealand; the giant lemurs and elephant birds of Madagascar; and the flightless geese of Hawaii[2-4]. (It is still debated[2] whether the late Pleistocene extinctions of most large animals of North and South America and Australia were similarly caused by the arrival of humans.) More recently, it has become clear that pre-industrial societies were also prone to habitat destruction on a scale sufficient to destroy them.

One such case involves the collapse of the Polynesian society that erected the famous giant statues of Easter Island. This collapse proves to have been at least partly caused by deforestation, documented by pollen records[5,6]. When Polynesians reached the island around AD 400, they found it covered with palms, other trees and shrubs. By AD 1500 the human population had grown to about 7,000 and had

Barren grasslands and the famous monolithic statues of Easter Island. The scene was formerly a palm forest. (Courtesy of Jo Anne Van Tilburg and David Ochsner.)

erected some 245 stone platforms, carved more than 800 giant statues and destroyed the forest so completely that its tree species are now extinct[7]. Deforestation had three harmful consequences: soil erosion, hence lower crop yields; no trees to build canoes, hence lower yields of fish, the main protein source on Easter Island other than chickens; and inability to erect statues (weighing up to 85 tons), which had probably been raised to an upright position with the help of logs used as levers. The human population now exceeded the carrying capacity of the island. Warfare, cannibalism and slavery became chronic, a warrior class took over, spear-points were manufactured in enormous quantities and people reverted to living in caves for defence. By the time that Europeans discovered Easter Island, they found a panorama of destruction: the population may have crashed, many of the statues had been toppled and intentionally decapitated during battles between rival factions, and the island had been converted to barren treeless grassland.

A second example is the collapse of the Anasazi, one of the most advanced pre-Columbian civilizations in the United States. When European explorers reached the deserts of the American south-west, they found gigantic, uninhabited, multi-storied communal houses or pueblos. The dwellings in Chaco Canyon, for example, contained up to 5 stories and 650 rooms, were constructed with more than 200,000 roof beams weighing an average of 275 kg and were the largest and highest buildings in the United States until the advent of skyscrapers in the late nineteenth century. Archaeologists have shown that the dwellings were built about 1,000 years ago and abandoned in the twelfth century. The prevalent view, based on tree-ring evidence for a period of low summer rainfall, is that abandonment was forced by drought. But although drought may have contributed, the Anasazi themselves also inflicted fatal blows on the fragile desert environment.

Betancourt and Van Devender[8-11] used plant remains in radiocarbon-dated pack-rat middens to establish Chaco's vegetational history. When construction of the dwellings began in the early tenth century, the cliffs were covered with pinyon/juniper woodland, which was then cleared for firewood over a radius of 20 km during the next 200 years. The logs to construct the dwellings were mainly ponderosa pine, hauled in via roads from sites mostly more than 40 km away. As pines became depleted, the Anasazi began in AD 1030 to haul spruce, fir and Douglas fir logs from distances exceeding 75 km. In addition, Anasazi desert agriculture depended on gravity-flow irrigation without pumps, so that irrigation would have become impossible if channel erosion eventually lowered the water level below the field level. With the need to scour over a growing radius for construction timber and fuel, as well as the possible collapse of the irrigation system, the Chaco dwellings had to be abandoned. At Chaco Canyon, as on Easter Island, the environmental damage was irreversible.

Other cases deserve brief mention. It has long been debated whether overgrazing, removal of plant cover and soil erosion contributed to the decline of the ancient civilizations of Greece and the Middle East. A recent study[1] of the Peloponnisos suggests an answer in the affirmative by documenting at least four cycles of settlement, erosion and abandonment between 2000 BC and the Middle Ages. Abandonment was caused by slope erosion and valley siltation, resulting from shortened fallow cycles, clearing of steep slopes, domestic grazing animals and neglect of terracing and check dams. In Polynesia there was massive forest destruction in New Zealand[12] and Hawaii; degradation of forest to extensive fern savanna useless for agriculture in the Cook, Society, Marquesas and Mangaréva islands; and destruction of the xeric vegetation of Kahoolawe Island, causing a steep population decline and abandoment of all but a few coastal settlements after the sixteenth century[5]. Many other possible cases, such as the collapse of Mayan civilization and the desertification of the Sahara, cannot be evaluated without detailed evidence.

Although the lack of such evidence until recently surely helped the myth of an environmental golden age to persist, there may be another reason for the myth. It used to be common for industrial societies to treat pre-industrial peoples as savage brutes, meriting extermination or at least disposession of their lands. In reaction to this appalling history, others have idealized pre-industrial peoples as gentle conservationists. Both views are equally false. Ever since humans acquired the capacity to affect their environment, all societies have faced similar problems of managing fragile natural resources and have risked self-inflicted tragedies. ☐

Observations on heredity in cats with an abnormal number of toes

THIS observation is concerned with a family of four male tabby kittens, all of which possessed the abnormality to a very market extent. This was the first family produced by a female tabby cat which, when born, was the most abnormal form which had come under my notice, possessing two extra toes on all the paws, i.e. seven on each fore-paw and six on each hind-paw. The extra toes (in the fore-feet) are those labelled A and B (in Figs. 1 and 2), and they confer the extraordinary breadth upon the foot. The most recently added is B, which is still partially coalesced with A, and has but one pad in common with it (Fig. 2)...There is seen to be an extra pad behind the additional toes, of which there is no trace in the normal foot." In the hind-paws (Figs. 5 and 6) "there is little doubt that the innermost toe I is the hallux lost in the normal foot...The second extra toe is that labelled A...On the under side (Fig. 6) all the toes have seperate pads, and there is an additional pad behind the extra toes," which is sometimes fused with that behind the normal toes.

From *Nature* **35**, 38; 11 November 1886.

Where does the message begin?

SIR—The remarkable accomplishment of cloning and sequencing the gene responsible for the X-linked form of the phagocytic disorder chronic granulomatous disease (X-CGD) on the basis of its chromosomal location alone, without reference to any protein, has recently been reported in these pages by Royer–Pokora *et al.*[1]. With the amino acid sequence predicted from the gene sequence, it should now be possible to identify and characterize the previously unknown protein responsible for this disorder. However, it seems possible that the true amino terminus of the protein has not been identified.

Royer–Pokora *et al.* conclude that translation of the X-CGD messenger RNA probably initiates at the second in-frame AUG codon, at position 322, because it occurs in a sequence that more closely resembles the consensus sequence for functional initiator codons, defined by Kozak[2] on the basis of observed sequences, than does that at the first AUG at position 208. The primary difference between the two is that the AUG at position 322 has an A nucleotide three positions upstream, as do 79 per cent of functional initiation codons, whereas at the first AUG there is a U, which is hardly ever observed at this position[2]. On the other hand, 95 per cent of known messenger RNA molecules have translation initiated at the most proximal AUG codon[2], and the importance of the most proximal position has been demon-strated directly[3]. The basis of the nucleotide preference observed three nucleotides upstream is not known. Therefore, the choice of neither initiation codon is compelling from just these considerations.

The reason for suggesting that translation of the X-CGD messenger RNA initiates at the first AUG is that the 38 extra amino acid residues indicated by the messenger RNA sequence are not random. In particular, the first 20 residues closely resemble the signal peptides that have been implicated in the co-translational passage of proteins into the endoplasmic reticulum as the first step in targeting the protein for secretion from the cell, insertion into membranes, or sequestration into at least some cytoplasmic compartments[4-6]. The pertinent properties are that this sequence;

Met-Leu-Ile-Leu-Leu-Pro-Val-Cys-Arg-Asn-Leu-Leu-Ser-Phe-Leu-Arg-Gly-Ser-Ser-Ala-

is positively-charged, has predominantly hydrophobic amino acids from residues 2 to 15, and ends with five polar residues typical of signal peptide cleavage sites. The only unfavourable aspects of the sequence are the Arg and Asn residues at positions 9 and 10, respectively, within the hydrophobic segment, but such residues are observed at low frequencies in similar positions in known signal peptides[7]. The predictive scheme of Von Heijne[7] considers the frequencies with which the 12 amino acids proximal to the signal peptide cleavage site, plus the two distal, are observed in known signal sequences. The relative likelihood of the first 20 residues constituting a signal peptide, with cleavage after Ala 20, was calculated to be + 5.6, which is well within the range for known signal peptides and outside that found for the terminal amino-acid sequences of cytoplasmic proteins[7]. The first eight residues are not considered in this calculation but are very like those in known signal peptides.

The nature of the X-CGD disorder is consistent with the protein responsible being situated in granules of phagocytes[8]. Proteins designated for such cell sites are often synthesized with signal sequences and are directed to the appropriate cell compartment after entering the endoplasmic reticulum[9-11].

SIR—We appreciate the comments and suggestions from Creighton[1] and from Ashworth *et al.*[2] regarding our predictions for the protein product encoded by the gene responsible for X-linked chronic granulomatous disease[2].

Creighton suggests that a non-consensus ATG at position 208 of our cDNA sequence might be the correct translation initiation site (rather than the consensus ATG at position 322 we favoured) and that the additional N-terminal extension encodes a signal peptide based on a predictive scheme of von Heijne[4]. As stated in our paper, no certain choice between these ATGs can be made from cDNA sequence alone. Our analyses of the sequence, albeit without the recent approach of von Heijne, led us to favour the ATG at 322. Creighton's proposal needs to be very carefully considered, but in light of our recent finding (R. Brown and S.H.O., unpublished data) that an intron interrupts the alanine codon he suggests as a signal peptide cleavage site.

Whatever the final resolution, the uncertainty in ATG assignment does not materially affect experimental approaches to identification of the protein *in vitro*. For one, the size difference between the proteins predicted from initiation at either ATG (minus the signal peptide if ATG 208 were used) is small. In addition, we are obliged to examine all cellular fractions to localize the protein to a specific compartment. Finally, initial results with antisera directed against a portion of the predicted amino acid sequences identify an *in vivo* protein located in membrane-rich fractions of granulocytes (M. Dinauer and S.H.O. unpublished data). Expression of transferred cDNAs will permit definitive assignment of the initiator codon and the possible role of the signal peptide proposed by Creighton in the targeting of the protein within the cell.

Although the suggestion of Ashworth *et al.*[2] that a region near the C-terminus of the predicted protein resembles a haem-binding site of a cytochrome P450 is intriguing, the significance of the limited resemblance they note is unclear.

Occam and mankind's genetic bottleneck

P442

SIR—In defending their support for and amplification of the view[1] that non-African human populations are descended from African populations via an emigrant stock that was of very small size, Jones and Rouhani[2] have exposed the weakness of their argument. It is true that such a bottleneck is an inevitable implication of their simple model. However, that model assumes that the β-globin non-coding sequences of DNA on which their argument is based are unaffected by selection, either directly or by linkage ('hitch-hiking'). This assumption is defended on two grounds. The first is that neutrality of non-coding sequences is implicit in most hypotheses of molecular evolution. But there is actually no evidence for this fashionable assumption. It is adopted merely because of the prejudices of those advancing the hypotheses, because it allows phylogenetic conclusions to be reached in molecular biology laboratories rather than at palaeontologists' benches, and possibly because it makes the models mathematically easier.

Jones and Rouhani tell us that their second reason for assuming neutrality is that, since there is no information on any selective forces affecting the variants they discuss, they "have, with Occam, chosen the more straightforward alternative"[2]. Let us not argue fruitlessly about what William of Occam really meant. In practice, science progresses by attempting to explain phenomena simply, by trying to simplify further, and by adding complexity only when necessary. But what is simpler in this case — assuming no selection and a bottleneck, or assuming selection and no bottleneck? Conceptually the two hypotheses are equally simple: the maths can be simplified either by leaving out selection or by assuming the population size to be effectively infinite. Indeed, the available data are consistent with innumerable combinations of values of the relevant variables — population number, selective coefficients, time and original allele-frequencies. One can, of course, reach conclusions about the values of some of them by making arbitrary assumptions about the values of others but there is no justification for doing so. We just have to admit our ignorance.

Jones and Rouhani are prepared to invoke selection when they need it: they argue against parallel evolution in various populations by recalling Sewall Wright's calculations of the unlikelihood of a chromosome rearrangement becoming established in a population if it is at a selective disadvantage in the heterozygous condition. Do they consider the β-globin sequences to be neutral or do they not?

Chernobyl fallout in size-fractionated aerosol

SIR—The Chernobyl accident first produced elevated radioactivity in ambient air in Switzerland on 29 April. Daily high-volume samples showed that the highest activities occurred on 1 May and had already decreased by two orders of magnitude by 8 May. The maximum values observed of ^{137}Cs (2 Bq m^{-3}) are about half of those reported from Studsvik[1].

To understand the interaction of these airborne fission nuclides with the environment, we need to know the carrier responsible for their long-range transport. We therefore measured activity distributions on size fractionated aerosol samples for typical fission products such as ^{131}I, ^{103}Ru, ^{132}Te and ^{137}Cs, using two different commercially available cascade impactors.

From 30 April to 13 May, an Andersen sampler collected aerosols in Spiez (total 570 m^3) and, from 2 May to 8 May, a low pressure Berner impactor[2] was intermittently in operation in Zurich (total 170 m^3). The impactors fractionate airborne particles into different size classes.

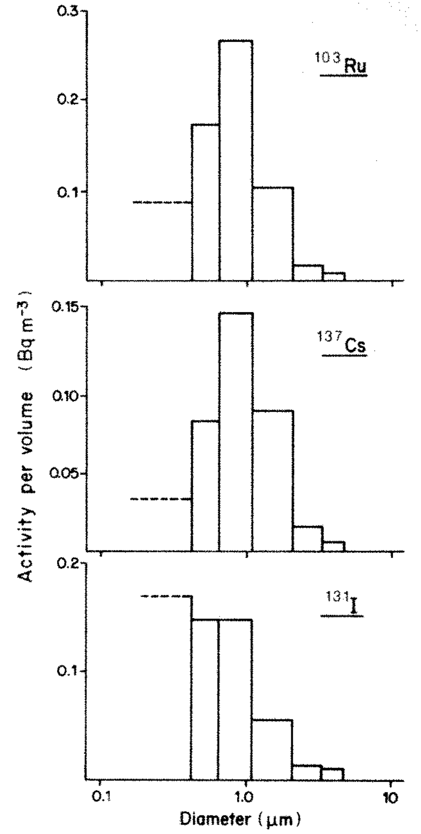

Fig. 1 Activities of ^{103}Ru, ^{137}Cs, and ^{131}I in size fractionated aerosol samples in Bq m^{-3} sampled at Spiez from 09:00 h April 30 to 09.00h May 13 using an Andersen sampler. Note that the low activities are due to averaging over the 14 day sampling period.

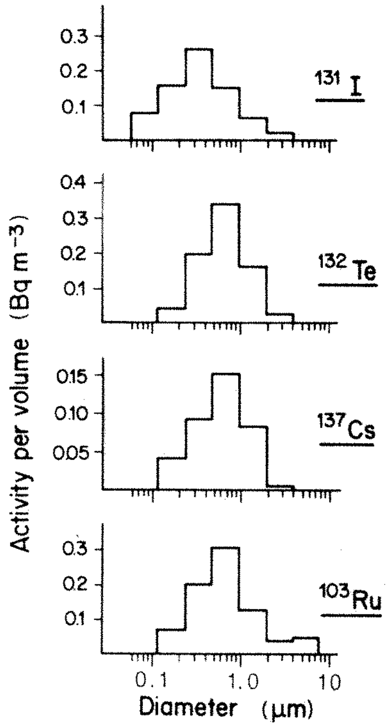

Fig. 2 Activities of ^{131}I, ^{132}Te, ^{137}Cs, and ^{103}Ru in size-fractionated aerosol samples in Bq m^{-3} sampled at Zurich-Hoenggerberg from 09:15 h—May 23:15 h May 6th using a Berner cascade impactor.

As Fig. 1 shows, ^{131}I has a rather different distribution from the other nuclides. Most ^{131}I is found in the size fraction on the backup filter (<0.47 μm), whereas ^{103}Ru and ^{137}Cs show a pronounced maximum at 0.93 μm (geometric mean diameter). The Berner impactor (Fig. 2). gives a similar distribution with the maximum for iodine at 0.35 μm and at 0.71 μm for ^{132}Te, ^{137}Cs and ^{103}Ru. Different distributions are due to the different cutoff diameters of the devices. The distributions for ^{137}Cs, ^{132}Te and ^{103}Ru are very similar to the concentration patterns of prominent ions such as NH_4^+ or SO_4^{2-} and NO_3^- as determined by ion chromatography (data not shown).

Measurements in Sweden [1], Finland[3], and Germany [4] have shown that ^{131}I was mainly (~ 80%) present in the gas phase. The adsorption of gaseous species onto aerosols is strongly surface correlated[5,6]; measured surface distributions for environmental aerosols usually peak at size fractions with particle diameters ≤0.4 μm (refs 7,8). We therefore conclude that the size distribution observed for ^{131}I does not reflect the primary particles released at Chernobyl but rather the surface distribution of the aerosols at the sampling site.

By contrast, ^{137}Cs, ^{131}Te and ^{103}Ru were presumably ejected as particles or attached very early to aerosols and grew by coagulation with other particles during transport. It is therefore reasonable that their size distribution resembles that of the main inorganic ions (sulphate, nitrate and ammonium) which may also be transported over long distances[9].

In contrast to the findings of Bondietti and Brantley[10], we found no increase of the activity median aerodynamic diameter during the measurement period. We think that this increase may not reflect the original release at Chernobyl, but be due to transport effects. Note that the size distribution of ^{137}Cs, for example, from the Chernobyl fallout is very similar to the size distribution in the fallout of nuclear weapons tests[11], in contrast to the size distribution found in the stratosphere, which is shifted towards smaller particles[12].

We have also measured fission products in sequential samples of the first rain at Zurich after 29 April. The activity distributions of the radionuclides were very similar to the concentration distributions of the ions, from which we conclude that the depletion mechanisms are quite similar for both groups. The activity ratio of ^{131}I to the other radioisotopes, such as ^{131}I/^{103}Ru in rain is about 5, whereas in the impactor samples it is near to one (integrated values from Fig. 1 or 2). This observation also indicates that in the atmosphere ^{131}I was mainly present as gaseous species and is depleted with high efficiency by rain.

Alimentary restrictions and ^{131}I in human thyroids

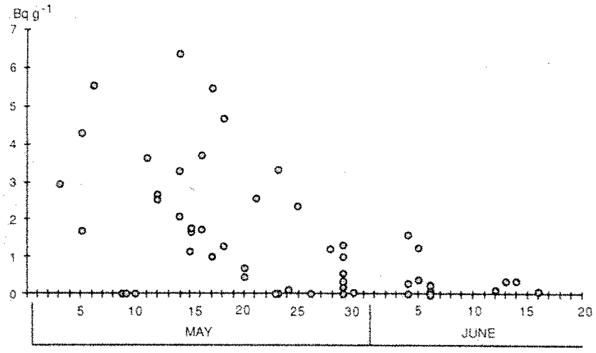

Fig. 1 ^{131}I activity as measured in 51 thyroid specimens in the period following the Chernobyl accident.

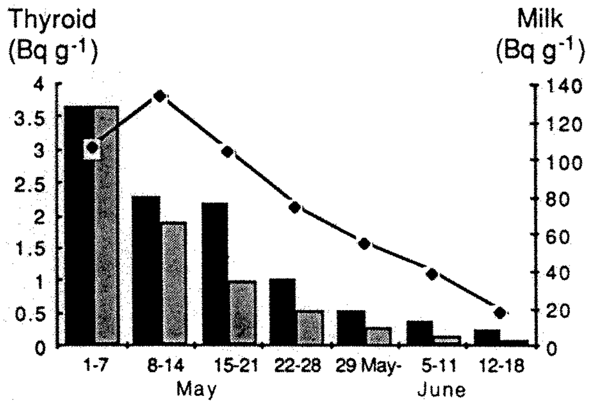

Fig. 2 Mean weekly ^{131}I activity in milk (continuous line) and in thyroid (black columns) during the 7 weeks following arrival of the radioactive plume. Stipled columns indicate the theoretically expected decay of radioactivity, starting from the levels detected in thyroid during the first week of monitoring.

SIR—Hill *et al.*[1] have reported measurements of ^{131}I during the period following the Chernobyl reactor accident. We have directly determined ^{131}I activity in specimens of thyroid gland obtained at autopsy from 51 adult individuals dying of accidental causes in the area of Genoa. Sampling started on 3 May 1986, 2 days after arrival of the radioactive plume over the area and one day before an abundant rainfall.

Each thyroid specimen was placed in the central well of a shielded NaI(T1) detector connected with a 1,024-channel spectrometer; radioactivity was measured against a ^{131}I standard having the same geometry.

Differences between individuals (Fig. 1) presumably reflect variable exposure. High levels of ^{131}I were detected from the beginning of radioactive fall-out. The decay of radioactivity in the following weeks was less pronounced than expected on the basis of the effective half-life of ^{131}I in thyroid (7.55 days) (Fig. 2), inferred from its biological (120 days) and physical (8.05 days) half-life.

Although these data are consistent with some persistence of the exposure to ^{131}I, the progressive decrease of radioactivity in the thyroid contrasts with the initial increase of ^{131}I in milk samples from the same area (Fig. 2), presumably reflecting the efficacy of alimentary restrictions introduced in Italy on 3 May. It is also significant that, on withdrawal of restrictions (16 May), the trend towards the loss of radioactivity in the thyroid was temporarily discontinued (Fig. 2).

The mean absorbed β dose was inferred from the ^{131}I activity measured in thyroid specimens, using an *ad hoc* conversion factor[2]. During the first 7 weeks following arrival of the radioactive plume, the mean (± SD) weekly absorbed doses were 3.66 ± 1.68, 2.31 ± 2.12, 2.20 ± 1.61, 1.02 ± 1.37, 0.55 ± 0.58, 0.38 ± 0.51, and 0.24 ± 0.17 μSv g^{-1} respectively. Assuming an average weight of 20 g per thyroid, it can be estimated that the cumulative load absorbed during that period accounted for a mean value of 207 μSv per individual. These estimates are higher than those made for adult individuals in southern United Kingdom, where the environmental contamination, as deduced from milk ^{131}I activity, was substantially lower than in our region[1].

Radioactive fallout swipe samples from Chernobyl

SIR—Significant quantities of radioactive fallout from Chernobyl were detected in aircraft swipe samples throughout the month of May, initially on flights from Moscow and, later, from London, New York and Tokyo. Swipe samples have provided valuable information on atmospheric nuclear weapon tests[1,2] in the past. The fallout from Chernobyl was measured in the swipe samples collected at Bombay from 2 May onwards. Though the radioactive plume rise at the accident site has been estimated[3] to be around a kilometre, atmospheric dispersion with time could carry the activity to higher altitudes which enabled its detection.

In all, 20 isotopes; ^{95}Zr, ^{95}Nb, ^{99}Mo, ^{103}Ru, ^{106}Ru, ^{110m}Ag, ^{111}Ag, ^{125}Sb, ^{127}Sb, ^{132}Te, ^{131}I, ^{134}Cs, ^{136}Cs, ^{137}Cs, ^{140}Ba, ^{140}La, ^{141}Ce, ^{144}Ce, ^{147}Nd and ^{239}Np were measured by high resolution gamma spectroscopy. Although the nature of the sampling does not permit quantification with respect to volume of air, useful information could be obtained by studying suitable radioisotope ratios.

Our results are generally similar to those reported by others[3-6]. Different isotopes of caesium, iodine, ^{132}Te, ^{140}Ba, ^{140}La, ^{103}Ru and ^{99}Mo were the major contributors to the activities measured in the samples. Comparisons with similar swipe samples collected after the last atmospheric test in 1980, which was a low altitude H-bomb explosion, show that in the present case the ^{137}Cs levels are about an order of magnitude higher and ^{103}Ru an order of magnitude lower. The levels of ^{132}Te and ^{99}Mo, are 10–100 times lower. The other major difference is that the ^{95}Zr concentration is 1000 times less, than from the samples after the last nuclear test.

Table 1 Activity Ratios (on 26.4.86) of fission products and ^{239}Np to ^{137}Cs in 5 swipe samples

	Origin of flight and the date of collection at Bombay				
Ratio of element to ^{137}Cs	Moscow 2.5.86	New York 5.5.86	New York 11.5.86	Tokyo 11.5.86	Tokyo 29.5.86

^{137}Cs activity (becquerels)	116	152	315	1241	427

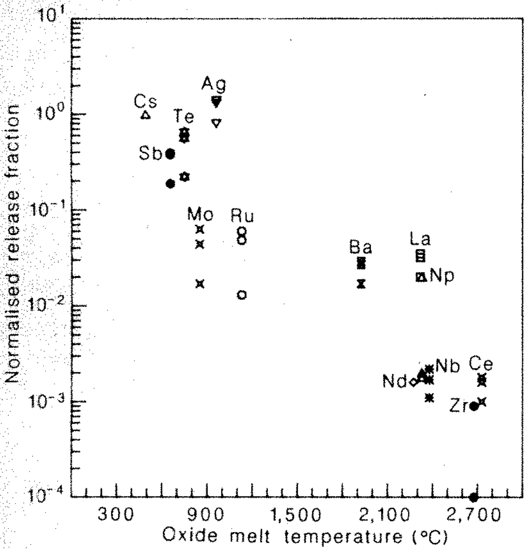

Fig. 1 Activity ratios of selected fission products with respect to ^{137}Cs. The activity of ^{137}Cs in the samples are also shown.

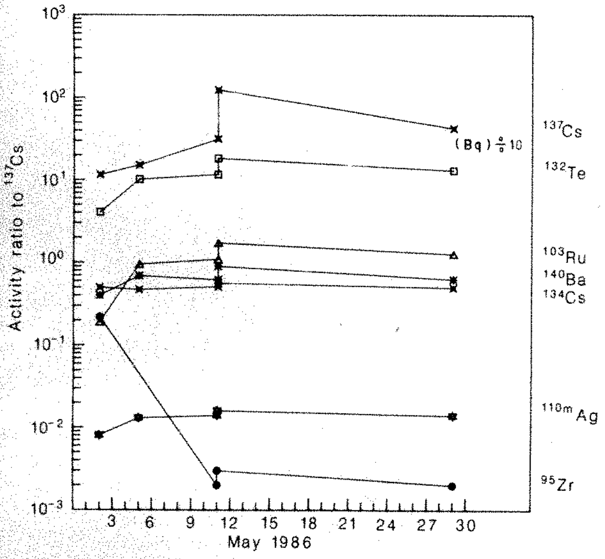

Fig. 2 Release fraction with respect to Cs plotted against fission product oxide's melting point.

The isotope activity ratios to ^{137}Cs (as on 26 April) in 5 of the samples collected during May are given in Table 1 and a few selected ratios are plotted in Fig.1. The ratios of elements whose oxides have high melting temperatures (for example Zr, Nb and Ce) with respect to ^{137}Cs were higher in the first sample collected on 2 May, probably representing the initial release from the reactor. Subsequent samples show higher relative concentrations of Ru, Te, Mo and Sb and, to a lesser extent, of Ba, La and Ag. The ^{131}I/^{137}Cs ratio variations in these samples did not show any set pattern, perhaps because much of the ^{131}I may be in vapour form[4].

Two estimates of the reactor fuel burn up have been reported[4,6], based on ^{134}Cs/^{137}Cs and ^{103}Ru/^{106}Ru ratio values of 0.5 and 4.5 respectively; we observed similar values for the ratios. We also obtained other ratios from the isotope pairs of the same elements such as ^{127}Sb/^{125}Sb, ^{136}Cs/^{134}Cs and ^{141}Ce/^{144}Ce, the last of which varied somewhat from sample to sample. We obtained reactor core inventories from the ORIGEN 2 code[7] for 1.8% enriched uranium Candu type reactor and compared them with the observed activity ratios. They correspond to a fuel exposure of around 650 d (700 d if 2.0% enriched U was used) though our ^{134}Cs/^{137}Cs also gave fuel exposure of 400d.

The release fractions, normalized to ^{137}Cs, vary with the melting point of the oxides of the fission products for the first three samples. The fractions for Sb and Te agree well with those documented for the PWR reactor core melt accident[8] while for other elements marked differences are observed. Deviations start from Mo onwards and increase with increasing oxide melting point, suggesting that there may have been only a partial core melt (Fig.2).

We thank V.K. Sundaram, Health Physics Division, for the ORIGEN 2 results and Dr V.K. Shukla, G.N. Shaikh and T.N. Mahadevan for help in sample collection.

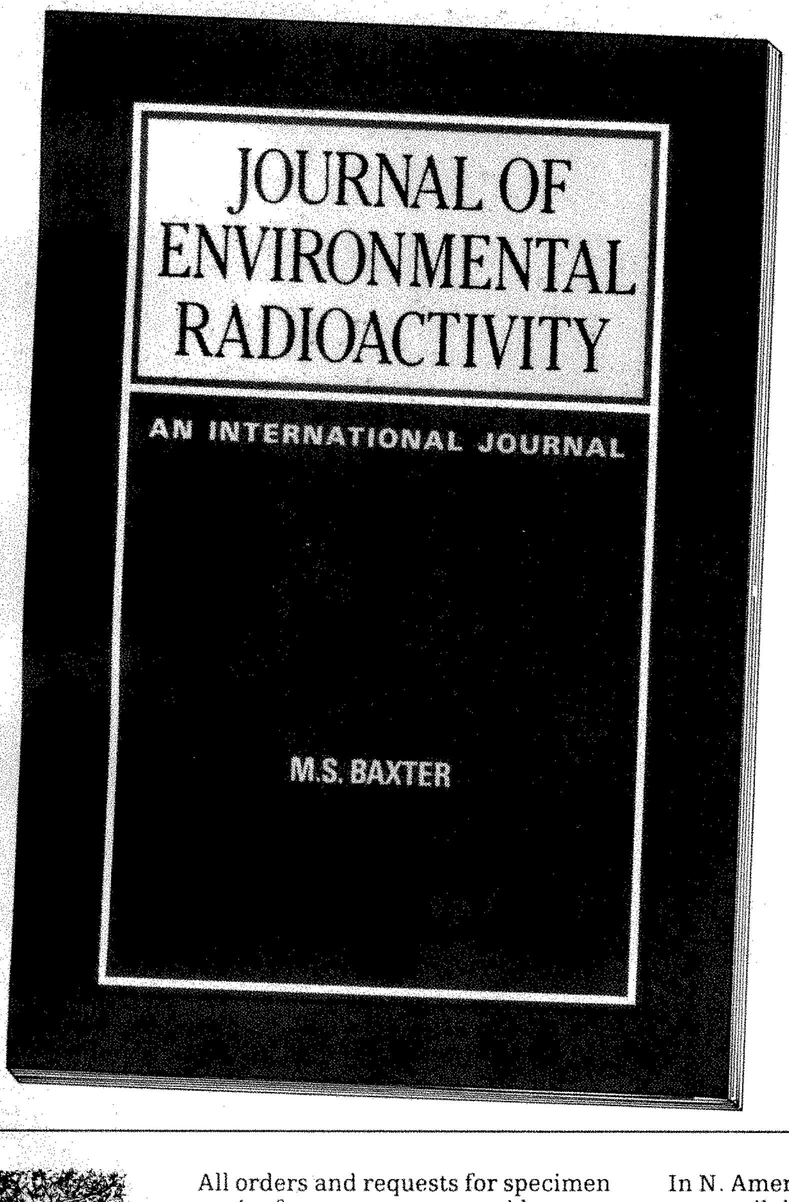
For research papers on Chernobyl

JOURNAL OF ENVIRONMENTAL RADIOACTIVITY



Editor:
M.S. Baxter, *Scottish Universities Research and Reactor Centre, East Kilbride, Glasgow G75 0QU, Scotland*

"Although many periodicals will take articles on environmental aspects of radioactivity, there is a good case for a journal specifically concerned with the subject. Now we have one, Journal of Environmental Radioactivity. Most of the papers published to date are naturally concerned with radioactive pollution from materials arising from nuclear bomb tests or from nuclear industry."

John Fremlin
Nature, September 1985

This review was, of course, written before the incident at Chernobyl. Many journals have already published "immediate" papers on its effects. However, there are and will be "long-term effect" papers which will be published continuously over the next few years.

Journal of Environmental Radioactivity is the obvious medium for these papers which will be featured regularly.

The journal accepts original contributions of 2,000 to 4,500 words (plus tables and figures); review articles, notes and conference reports are also accepted. There are no page charges.

For further information write to the publisher or the Editor.

Subscription Information
Frequency: 6 issues in 1 volume.
Volume 5 1987

Price: U.K. delivery £95.00.
Overseas delivery £105.00/$174.00
The £ sterling price is definitive.
US$ prices are subject to exchange rate fluctuations.

All subscriptions are airspeeded at no extra cost.

ELSEVIER APPLIED SCIENCE PUBLISHERS

ANNOUNCING TWO NEW JOURNALS FOR 1987

Journal of Chemical Neuroanatomy

Editor: H.W.M. STEINBUSCH

Laboratorium Voor Farmacologie,
Vrije Universiteit, Amsterdam, The Netherlands

Advances in investigative techniques and methods have led to vastly-improved microscopic resolution of the structure and function of neural cells, and especially information about receptor and transmitter localisations and their mechanisms of action. This major new publication in the neurosciences will specialize in original research papers specifically relating to transmitter-characterized systems in the central and peripheral nervous tissue, with a special emphasis on methodological papers. Inter-disciplinary, developmental, evolutionary, ageing and behavioural investigations relating to one or more neuronal systems will also be encouraged.

To be published bi-monthly. Prices to be announced.

Microbial Ecology in Health and Disease

Editors-in-Chief

P. BORRIELLO
Division of Communicable Diseases
Clinical Research Centre, Harrow UK

C. RUSSEL
Department of Oral Medicine
University of Manchester, UK

The journal will consider manuscripts primarily on the human microbial flora, but also that of other animals, and its developments and interactions.

Topics will include

★ investigative methods ★ animal and *in vitro* models ★ the effect of anti-microbials or diet on the commensal flora or its development ★ the role of immunological and other mechanisms which help maintain a stable flora ★ the clinical applications of the commensal flora in the treatment and prevention of disease ★ alterations in the host environment (eg. colostomy, dental treatment).

To be published quarterly. Prices to be announced.

Pragmatism in public health

Alan Glynn

Inventing the NIH: Federal Biomedical Research Policy, 1887–1937.
By Victoria A. Harden.
The Johns Hopkins University Press:1986. Pp.274. $32.50, £25.50.

DAVID Smyth, the physiologist, once said "If primitive man had something on his mind it was probably because he had nothing in his stomach". The primitive hunger which led eventually to the founding of the National Institute of Health was simply for public health. The NIH's forerunner was the Laboratory of Hygiene set up in 1878 on Staten Island, New York, to detect infections among immigrants by using the new science of bacteriology. The Laboratory was part of the Marine Hospital Service, itself founded in 1798 to provide medical care for seamen.

Victoria Harden has drawn on numerous primary and secondary sources for her analysis of the forces which led to the establishment of the NIH in 1930. The author is not a scientist and her book is not a history of bench science or laboratory medicine. It is a history of the pressures, scientific and political, private and public, which shaped United States federal policy on biomedical research. In the end it was this policy which, after 50 years of struggle, allowed the change from a one-man, one-room laboratory to the first National Institute of Health. Development of federal policies over 50 years produced eleven Institutes spread over 317 acres at Bethesda in Maryland, employing 14,000 people and using or distributing 30 per cent of all American health research funds.

There was a false start early on. The value of "sanitary science" had become apparent during the Civil War and after the War attempts were made to enlarge and reform the Marine Hospital Service by, among others, John Shaw Billings, now best known as the initiator of the *Index Medicus*. Billings failed at first but an epidemic of yellow fever in the Mississippi valley led to the formation of a new National Health Board with him in charge. The Marine Hospital Service fought back and, starved of funds, the Board soon withered away. This set a recurring pattern. Reformers, and there were many, came up against not only the natural inertia of a conservative Congress or President but the opposition, open or covert, of the grandees of the Marine Hospital Service who were determined that whatever change had to come they were going to remain in charge.

Harden has, rightly, followed through particular lines of development rather than given a strictly chronological account. There is a list of the principal advances made by workers in the Laboratory of Hygiene, but for those who lack a detailed knowledge of American history a table of the main political events would have been more useful. The Laboratory flourished during the "progressive era" before the First World War. The War, and the work it demanded, stimulated scientists to think of major collaborative research projects embracing many disciplines, though there was still an instinctive distrust of the institutionalization of science.

The book outlines the uneasy and shifting alliances between scientists, health workers and reforming politicians, and helps us to understand an apparent paradox: how a country with a strong philosophy of self-help and freedom from government interference managed to create the largest and most successful laboratory ever devoted to biomedical research almost entirely on government money. Except for one or two brief references, for Harden Europe does not seem to exist. This is a pity, because it is fascinating to compare the events and philosophies she discusses with what was happening at roughly the same time on the other side of the Atlantic.

For example, in its early days the Laboratory of Hygiene was only authorized to deal with practical matters of infectious disease. Its early researches into pellagra or even water pollution were, strictly speaking, illegal uses of government money; indeed a separate appropriation for research was not made until 1907. Sir John Simon in England had faced similar problems 40 years before, when he imposed his own ideas on a vague remit from the Privy Council and eventually persuaded them to authorize, as he put it, "investigations, not necessarily connected with our practical business at the moment . . .". That was in 1865, and because governments everywhere "respond to pestilences" Simon was no doubt helped by the spread of cholera and cerebro-spinal fever in Europe and the arrival of yellow fever in Swansea. As a distinguished pathologist and surgeon, Simon received much help and backing from his professional colleagues whereas the early proponents of the NIH were sometimes in conflict with the American Medical Association.

Perhaps the closest parallel in Britain is the setting up of the Medical Research

The National Institutes of Health in the 1980s, showing only part of the Bethesda complex. On the right is Senator Joseph E. Ransdell, sponsor of the bill that transformed the Laboratory of Hygiene into the NIH. (*Pictures respectively courtesy of the NIH and from the book under review.*)

Council, the origins of which go back to the Local Government Board of 1871 and more immediately to the Medical Research Committee of 1913. Perhaps because of the tradition of Chadwick, Simon and Farr there seems to have been less worry in Britain than in the United States about the state getting mixed up in health and research, and the MRC was protected from direct ministerial interference at least until the Rothschild era. Although the NIH also achieved considerable scientific independence, Congress continues to try to influence its projects — as in the bill to set up an Institute of Nursing, vetoed last year by the President.

Despite the prosperity of the 1920s, progress in public health was difficult under the "new era" politics of Coolidge. Coolidge never mentioned the subject in a speech, and though treasury secretary Mellon was more favourably inclined he could rely on the director of the budget, Herbert Lord, to keep the purse strings tightly drawn. Lord combined a professional dislike of spending money, especially on research, with the Christian Scientist's belief in its futility.

By the late 1920s, the story takes on some of the inevitability of a Greek tragedy. Harden describes in detail the negotiations through which, after many years of struggle, Congress was persuaded to pass the Parker bill giving more freedom to the Public Health Service. Eight days later Coolidge vetoed it. Again there is a detailed but lively account of the haggling and manoeuvering in Congress. This time the Ransdell bill, which specifically set up the National Institute of Health, failed partly because of opposition from Parker who was smarting at his own defeat. At last Coolidge went and Lord retired. After more hectic activity, both bills passed both houses and were signed by President Hoover. It was 1930 and the Great Depression had already started.

Throughout this story there are many colourful and interesting characters. Yet I have the impression that the colour and the passion have been carefully filtered out in the interests of analytical clarity. This is unfortunate for the amateur historian or the general reader, but for those who want to influence public health policy the message comes through clearly. They must educate the public, the legislators and the administrators. And education here means both short- and long-term campaigns. It means using every effort to win over pressure groups, influencing the influential and converting the doubtful. Well-timed epidemics are always a help. In short this is an excellent, though rather dry, textbook for wets. □

Signal studies in psychology

D. Aled Jeffreys

Human Brainwaves: The Psychological Significance of the Electroencephalogram. By Jacob Empson. *Macmillan, London/Stockton, New York:1986. Pp.126. Hbk £25, $50; pbk £7.95.*

In 1934, Adrian and Mathews confirmed and extended Berger's earlier but largely ignored discovery that small, continually varying, electrical signals could be recorded from the human scalp. These electroencephalograms (EEGs) have been extensively studied over the past 50 years but, even so, relatively little is known about their origins and significance. In contrast to their well-proven clinical applications, therefore, the "spontaneous" EEG signals have had only limited uses in research into normal brain function. They have nevertheless proved to be useful indicators of the level of consciousness and, in particular, of the different stages of sleep. There have also been encouraging results from experiments in which stimulus-induced changes in the EEG — the so-called event-related or evoked potentials (ERPs or EPs) — have been used to investigate cognitive and, to a lesser extent, sensory aspects of brain function.

Newcomers to such electrophysiological studies of the human brain are unfortunately confronted with a vast and specialized literature, often with a high technical content. Jacob Empson has tried to alleviate the problem by providing a simple, non-technical introduction to the use of the EEG and ERPs in cognitive psychology. The first two chapters include brief accounts of the history of the EEG and of modern encephalographic practice; descriptions of the typical characteristics of the EEG and their use in the assessment of states of consciousness; and discussion of various theories on the origins of the alpha rhythm. There are also individual chapters on event-related (and slow) potential studies of psychological processes, and on the EEG and localization of function in the brain. Two final chapters are devoted to the author's particular interests of normal and abnormal aspects of sleep.

As expected, the book does not provide detailed reviews of the literature but instead contains selective summaries of what the author judges to be the most important experimental findings. One can, in several cases, argue with some of his particular choices or omissions; and also perhaps complain that a short summary similar to that given in the section on event-related potentials was not provided in every chapter. But such shortcomings must be judged against the difficulty of the author's task. The quality of production is quite good except that the print on several pages of my review copy was slightly smudged.

The book is written in a simple and clear style, although occasional sentences have uncertain meaning and, in two cases (pp. 17 and 31), do not make sense at all, presumably because of missing lines or words. On the whole, however, it is easy to read and meets its main objective of providing a coherent and non-technical survey of the topic. *Human Brainwaves* will serve as a useful primer for psychology students and others who need a general introduction to non-clinical, psychological aspects of the EEG. For those who wish to progress further, each chapter has a selected bibliography of more comprehensive review papers. □

Material success

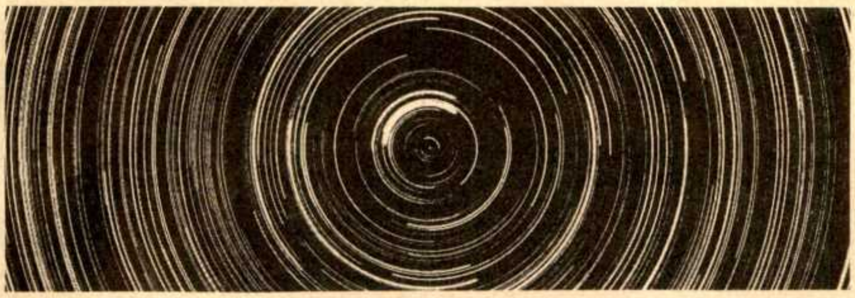
Charles Newey and colleagues

Encyclopedia of Materials Science and Engineering. Editor-in-chief Michael B. Bever. *Pergamon:1986. Eight volumes, pp. 6,015. £1,350, $1,950.*

The *Encyclopedia of Materials Science and Engineering* (EMSE) contains some five million words in seven volumes, plus a volume of indexes. How could a single reviewer possibly do justice to such a massive effort?

Depending on their stance inside or outside the "materials community", different users will look for different things from this encyclopaedia and one person could not hope to have a representative view. Further, review of EMSE requires assessment of a project planned by about 50 people and implemented by nearly 1,300 contributors writing over 1,500 entries. So, in keeping with the traditions of The Open University, we adopted a team approach. What follows is the essence of our corporate appraisal.

A good test of the usefulness of any encyclopaedia is to see how it performs against a list of topics you would expect or like to see covered. Our list included topics as diverse as Kyropoulos crystal growth, zeolites, charged dislocations, bubble memories, pyrometry, mercury reserves, globular proteins and value analysis. EMSE passed with flying colours, only failing on design for recycling (but recycling is well covered) and charged disloca-



The Earth moved — star tracks on an 8-hour exposure taken by a fixed camera pointed towards the North Pole; the boldest trail near the centre was made by Polaris. The picture is taken from the new paperback edition of Orbiting the Sun: Planets and Satellites of the Solar System *by Fred Whipple (reviewed in* Nature *294, 21; 1981). Publisher is Harvard University Press, price is $9.25, £6.75.*

tions (hardly surprising). In fact, the coverage is much more diverse than this with treatments of topics not conventionally associated with the books' title, for instance design, safety and health, materials and machines in antiquity, materials economics and management, art materials, newsprint and many materials of biological origin.

The Systematic Outline of EMSE (see Vols 1 and 8) groups the article titles under the 45 main subject headings used in the commissioning; they cover the production of materials, their nature and applications, property and structure assessment techniques, surface phenomena and processes, and more general topics such as mineral resources and management, and economics. These are further subdivided "as each subject dictates". The Introduction states that the space devoted to each of these sub-sections is in relation to its scientific, technical and industrial importance but we are given little insight into how this was assessed. The basis of selection must, in the end, be subjective and the updating policy will show whether the editors have met their goals.

The 1,570 articles are arranged alphabetically, which is a rather mixed blessing. This format should force users to look outside their specialities and, one hopes, help the editors to achieve their aim of cross-fertilization. The juxtaposition of "Titanium Alloys" with "Timbers from Various Geographical Locations" and "The Effect of Tax Upon Materials Policy" demonstrates this amply. On the other hand, the scheme puts a lot of stress on the cross-referencing system and it doesn't hold up too well, especially in terms of alternative titles (for example, "glassy" and "amorphous"). In addition, because the articles are not grouped under, say, specific materials, properties, processes or artefacts, the subject index — which is in Vol. 8 and very thorough — is an absolute must if you are looking for something specific.

Basically, EMSE consists of two types of entry: specific articles on particular topics in the science and engineering of materials, and articles of a more general kind. By and large the specific articles are authoritative, if succinct, treatments of their subjects but there is considerable variation in the level and approach. Perhaps this is inevitable, given the need to involve so many different authors each with their own ideas about the task, but there does seem to have been a certain unwillingness either to give clear briefing or to wield the editorial pen in the quest for consistency.

It is with the general articles that EMSE is clearly trying to be more than a conventional encyclopaedia. These are either reviews (for example "Electrical Materials — An Overview" and "Energy Considerations in Metals Production") or articles of an integrative nature ("Ceramics: Relation of Microstructure to Processing History", "Product Liability and Materials" and "Design and Materials Selection and Processing", for instance). The integrative articles are particularly informative and stimulating; they are good illustrations of the way to link aspects of materials that are often treated in isolation and, therefore, inadequately. Their inclusion is a clear manifestation of the editors' laudable desire to lower the barriers between disciplines. But beware, you will not find these gems in the subject index — for these you will need to use the Systematic Outline (Vol. 8).

In addition to unevenness in the level of the articles, the work can also be criticized for its slight bias towards the United States, and for a hint of partisanship. However, at this early stage in what should be an evolutionary process for EMSE, we will call this carping and trust that the balance is adjusted in the next edition.

The editors have tackled an enormous challenge and have met with considerable success. These volumes will be an important reference source for all scientists and engineers involved with the properties, processing and uses of materials, and especially for teachers of courses in the materials field. ☐

Charles Newey, Mark Endean, Peter Lewis, Nick Reid, Graham Weaver, George Weidmann and John Wood are members of the Materials Discipline, The Open University, Walton Hall, Milton Keynes MK7 6AA, UK.

Living for physics

Michael Holwill

Introductory Biophysics. By M. Cerdonio and R.W. Noble. *World Scientific:1986. Pp.216. £20.25, $25.30.*

For those who browse among the shelves of libraries or bookshops, the title of this book and the attractive seascape on the dust-jacket will provide little indication of the contents. It is not an introductory text for students embarking on a course in biophysics; rather, it is aimed at scientists with a reasonable background in physics, particularly in thermodynamics, and it is intended to demonstrate that the basis of living systems can be understood and explained by the application of physical principles. This is not a new concept, but recent developments in both molecular cell biology and irreversible thermodynamics make it appropriate to present a modern account of the ideas concerned.

After a brief description of the characteristics by which living systems can be identified, and a chapter dealing with the structure and organization of those systems, from viroids through bacteria to multicellular organisms, the authors apply physical ideas to a number of biological areas before discussing, in the final chapter, the origins of life. The chapters are essentially independent, each containing some interesting features but having little direct relationship to the others. There is, in fact, much of importance and value in the book, but the rather dated diagrams (which vary considerably in style and quality) and the use of old-fashioned units (for example, "entropy units" instead of $J\ K^{-1}\ mol^{-1}$ and "calories" for joules) detract from the modern scientific approach.

It is convenient to have, collected together in a single volume, accounts of the essentials of various physico-chemical processes and techniques relevant to a comprehensive examination of the nature and development of living systems. By reducing the space occupied by some of the diagrams, however, a little more introductory material could have been added without the need for additional pages, and this would have increased the appeal of the work to the great number of scientists who have a general interest in this controversial topic. In the final chapter the authors provide some pertinent insights into how thermodynamics, chemical kinetics and fundamental particle physics may be of importance in specifying evolutionary processes, but they have not capitalized on the material earlier in the book by giving a clear summary of the current status of this analytical study. ☐

That certain time in history

W.H. Brock

The Age of Science. By David Knight. *Basil Blackwell: 1986. Pp.251. £17.50, $24.95.*

THE reappraisal of the Victorians began in the 1940s. Much derided in the 1920s, today even politicians are reminting a specially-selected set of their "values" for the 1980s. Notwithstanding the material and cultural gaps between 1986 and 1886 or 1836, much of our present world can be clearly seen as derived from the Victorians — notably because of the vigorous export, through travel and emigration, of Victorian institutions and attitudes overseas, including parliamentary government, schools and universities, and the civil service, and religion and attitudes towards women and the family. Arguably, even the harmonies of contemporary popular music are those of Victorian church music. And, outside the relativistic and quantum boundaries of atomic physics and astrophysics, our vaunted twentieth-century science is essentially Victorian in origin.

In *The Age of Science,* David Knight, the most prolific of contemporary English historians of science (this is his eighth book), examines the scientific world-view in the nineteenth century. Although we may well believe that our present era is unprecedented in its domination by science, the reader will be persuaded by Knight that science equally dominated nineteenth-century thought and debates on religion, education, literature and the economic viability of the nation, though in a very different manner to our own. Here was a period before disciplines became so specialized that their practitioners became alienated from one another, when scientist, clergyman, writer and artist still spoke a common cultural language, and when science was ambitious, cocksure of progress and in its hegemonic role as the Church Scientific. As Knight points out, whereas historians may (wrongly) ignore the impact of science on earlier centuries, science cannot be left out of the narrative of Victorian history or of the historians' repertoire of explanations of what happened in history.

Knight writes deftly and entertainingly. Whether examining Anglo-French scientific rivalry, the challenge of German science, Victorian criteria for science and pseudoscience, the use and significance of scientific illustrations, symbols and jargon, the symbiosis of Victorian science and religion, or the slow erosion of scientific certitude, he wears his learning lightly. *The Age of Science,* a summary of the specialized reading Knight has done during the past 20 years, is a *tour de force.* It not only succeeds in making the history of science popular, but restores its 1950s role as a bridge between the cultures and disciplines which are the consequence of the Victorians' age of science. □

Cold comforts

Beverly Halstead

How to Deep-Freeze a Mammoth. By Björn Kurtén. *Columbia University Press:1986. Pp.121. $16.96.*

A SCIENTIST'S general musings in a series of light essays on his subject are the dread of reviewers; few ever rise to the riveting heights of a Stephen Jay Gould. Björn Kurtén's slim volume, however, is well above the average. Kurtén specializes in the study of mammals of the Ice Age, and he has written fictional accounts of the life and times of the period.

Most of the essays deal with aspects of the Pleistocene, but also cover such topics as the third early bird *Archaeopteryx,* the early history of continental drift and the great Messinian salinity crisis when the Mediterranean dried out. This last event came to light when salt deposits 1.5–2 km in depth were discovered during the deep-sea drilling prograamme; after the drought came the flood, as the Atlantic poured in through the Straits of Gibraltar — the largest waterfall in Earth history.

It is, however, in writing about the Pleistocene that Kurtén has the surest touch — he does in fact explain how to deep-freeze a mammoth. It has happened but rarely. Normally the outer layers freeze but the deeper parts putrefy and all that remain are bones and bacteria. However, on a southern-facing slope in winter, it is possible for an entire animal to be freeze-dried, and Kurtén describes the discovery of a 30,000-year-old bison from Alaska which made a palatable stew.

There is, too, an essay on Piltdown Man; here, being a Finn Kurtén misses some of the subtlety of English humour. He refers to the "elephant club" from Piltdown that had been carved with a steel knife, but this unique artefact was seen by all, even the duped Sir Arthur Smith-Woodward in his book *The First Englishman,* as akin to a cricket bat. What else would the first Englishman require? The first European in the form of the now-notorious Petralona skull from Greece is featured, but in this case the discussion verges on the technical as Kurtén has been personally involved. In general, though, he has a light touch. Most of the essays are very readable, and the first and last of them are outstanding.

In the first, entitled "The Two Cultures", Kurtén contrasts the fundamental difference between physics and chemistry on the one hand, and biology on the other, expressing with great clarity the attitudes of many practitioners of the "woolly" sciences:

> But the world of physics is no more than a corner of the world of science. A man is greater than a star. A bacterium is greater than a star. A star cannot become very much else than a star — but bacteria have evolved into men .... Biology is the study of individuals, all of them unique, in inexpressible multiplicity and richness. And so the world of biology is something very different from the world of physics and calls for a different approach and different concepts.

The last essay is on cave art. It may be wondered if there could possibly be anything more to say that has not already been said many times before, but one surprising fact is that it appears that the Ice Age was a Golden Age: there was an abundance of food and the lifespan of human beings was not paralleled until virtually the present day. Furthermore, when cave art is examined from the standpoint of a zoologist an unusual perspective emerges: a male reindeer on heat or seals swimming upside down, there is a remarkable precision of observation. Kurtén suggests that many of the paintings may have been for children, in fact for their education. Interestingly, children's footprints are common on the floors of these caves. It would be important for them to recognize the animal's state and hence predict its behaviour.

When it comes to the portrayal of the human form, Kurtén points out that here too there is great accuracy of observation. He notes that many examples of cave art portray sexually inviting attitudes and are not dissimilar to photographs in pornographic magazines of the present day. The vulva is seen frontally, inverted and also from the back, open for penetration. Kurtén sees "unabashed sensual joy and tenderness" in all this. One has the distinct impression that palaeolithic man had a very great interest in and knowledge of sex, and he seems to have portrayed many species including his own in states of sexual arousal. Kurtén must surely be right; it must have been a Golden Age. □

Cost-effectiveness of short-term tests for carcinogenicity

Lester B. Lave & Gilbert S. Omenn

Most chemicals to which we are exposed are not properly tested for carcinogenicity. The latest methods of* in vitro *testing provide a way of screening with sufficient accuracy to remedy this situation.

CONCERN about the dangers to health from exposure to toxic chemicals is increasing and all Western nations have developed elaborate schemes for regulating their production and use[1-6]. At present, decisions are made based primarily on long-term animal bioassays[1] which cost more than $1 million for each chemical and take 2-4 years. Here we present a framework for assessing the effective and efficient regulatory use of inexpensive, short-term *in vitro* tests and illustrate its application with data from an international collaborative testing programme[7].

The framework

Even though scientific data are rarely conclusive they provide the foundation for regulatory decisions[8] on whether a chemical should be regarded as carcinogenic or not at a particular exposure level. Carcinogenicity is particularly difficult to investigate because the causal mechanisms are far from fully understood, the period between exposure and onset of the disease may be decades, data on levels, routes, and time of exposure are generally poor, and susceptibility may vary due to predisposing genetic traits, pre-existing illnesses, personal habits such as cigarette smoking, and exposures to other chemicals that interact with the chemical of interest[9,10]. Ideally, current data would correctly classify all chemicals into true positives (TP) and true negatives (TN); unfortunately, it is inevitable that some misclassifications, false positives (FP) and false negatives (FN), will occur. Society should attempt to minimize the sum of the costs of testing and of misclassification.

In Fig. 1 we assume that either 2% or 10% of all chemicals are carcinogens. Measuring the cost of additional testing is straightforward, but what are the social costs of misclassification? It is not easy to generalize about the social costs of continued exposure to a carcinogen (FN). For example, lax standards for asbestos have resulted in hundreds of additional cancer cases each year. In contrast, lowering the benzene standard in the US from 10 to 1 p.p.m. in air was estimated to save less than one cancer per year. Respecting society's deep concern, we put a value of $10 million on a FN.

Estimating the social cost of a FP may be even harder, since it involves regulating a chemical needlessly. Capital and operating costs of exposure control equipment vary. If chemical production is discontinued, there is loss to the economy and substitutes have to be found. Cyclamates and the detergent nitrilotriacetic acid, both of which have been banned, are probably good examples of FPs. Substitutes may also turn out to have health risks, perhaps even greater ones. We put a cost of $1 million on a FP. For our purposes, the

a, Assume 2% (1,000) of 50,000 chemicals are carcinogenic

True biological activity

		Carcinogenic	Non-carcinogenic
In vitro test results	Potentially carcinogenic	TP 900	FP 4,900
	Not potentially carcinogenic	FN 100	TN 44,100

Social costs ($000 million)		
of false positives		
4,900 × $1 million	=	$4.9
of false negatives		
100 × $10 million	=	$1.0
Total	=	$5.9
Cost of testing		$0.4
Total social cost		**$6.3**
Social cost no testing, 1,000 FNs		
1,000 × $10 million		**$10.0**

b, Assume 10% (5,000) of 50,000 chemicals are carcinogenic

True biological activity

		Carcinogenic	Non-carcinogenic
In vitro test results	Potentially carcinogenic	TP 4,500	FP 4,500
	Not potentially carcinogenic	FN 500	TN 40,500

Social costs ($000 million)		
of false positives		
4,500 × $1 million	=	$4.5
of false negatives		
500 × $10 million		$5.0
Total	=	$9.5
Cost of testing		$0.4
Total social cost		**$9.9**
Social cost no testing, 5,000 FNs		
5,000 × $10 million	=	**$50.0**

Fig. 1 Social costs of testing chemicals for carcinogenicity. Illustrative analysis of consequences of FP (false positive) and FN (false negative) results, assuming that either *a*, 2% or *b*, 10% of chemicals are true carcinogens for humans, that the *in vitro* tests have a specificity and sensitivity of 90%, and that the cost of testing is $8,000 per chemical (test set 6).

critical assumption is that an FN costs ten times as much as an FP

As shown in Fig 1, there may be 1,000 or 5,000 unrecognized carcinogens among the 50,000 chemicals in widespread use The International Agency for Research on Cancer and the US National Toxicology Program list fewer than two dozen recognized human carcinogens[11,12] The current cost to society of FNs, therefore, may be $10,000 million to $50,000 million (at $10 million per carcinogen) These figures are disconcerting They are the hidden costs of an industrial society using chemicals with little knowledge about their potential carcinogenicity (or other adverse effects)

With a test system 90% accurate for both carcinogens and non-carcinogens and costing $8,000 per chemical, social cost would be $4,900 million for FP plus $1,000 million for FN (Fig 1*a*) Adding a testing cost of $400 million, social cost would be $6,300 million But if 2% of the 50,000 chemicals in use really are carcinogens, they have a social cost of $10,000 million The test system would lower this to $6,300 million If 10% are carcinogens, the test system would lower social cost from $50,000 million to $9,900 million

How high could misclassification be and still make the testing worthwhile, under these assumptions? If 2% of chemicals are carcinogens, the classification accuracy must not be lower than 84% for testing to be better than no testing If 10% are carcinogens, the classification accuracy need only be 52% Alternatively, if a slightly better test was available, one with 91% accuracy, it would be worth $11,800 or $19,000 more per chemical tested, assuming 2% or 10% of chemicals are carcinogens respectively

The above framework highlights the data required to make better social decisions about toxic chemicals the cost and accuracy of various carcinogenicity tests, the number of chemicals and proportion that are carcinogenic, and the social costs of false positives and false negatives Testing 50,000 chemicals in long-term animal bioassays is neither feasible nor cost-effective It is thus not surprising that increasing effort is being invested in the development and validation of many inexpensive, short-term tests *in vitro*[7,13–17] But misunderstandings remain about how accurate these tests would have to be to prove useful for regulatory decision making even though the 'gold standard', the long-term animal bioassay, itself has major limitations, both statistical and biological To be useful, a single short-term test need not be completely accurate, and the tests need not be useful for all classes of chemicals Short-term tests are inexpensive to replicate and provide information about dose-response relationships and mechanisms of action of chemicals, rather than simply counting the numbers of tumours in exposed animals

Table 1 Test chemicals carcinogen classification based on animal bioassay data[7]

Carcinogens	**Non-carcinogens**
4-dimethylaminoazobenzene (butter yellow)*	3,3′,5,5′-tetramethylbenzidine
chloroform*	4-dimethylaminoazobenzene-4-sulphonic acid Na salt
urethane*	pyrene
DL-ethionine*	α-butyrolactone
hexamethylphosphoramide (HMPA)*	anthracene
ethylenethiourea*	1,1,1-trichloroethane
diethylstilbestrol* (DES)	dimethylformamide
safrole*	diphenylnitrosamine‡
3-aminotriazole*	dinitrosopentamethylene tetramine
o-toluidine hydrochloride*	isopropyl-*N*-(3-chlorophenyl)carbamate

N-nitrosomorpholine	
methylazoxymethanol acetate	
hydrazine sulphate	
cyclophosphamide	
epichlorhydrine	
4,4′-methylenebis-(2-chloroaniline)(MOCA)	
2-acetylamino-fluorene	

* 'Problem carcinogens'

† Classification changed from non-carcinogen to carcinogen as a result of the testing and excluded from the analysis

‡ Diphenylnitrosamine was re-classified when animal bioassay data became available, and is now included as a carcinogen

Test data

The short-term test framework can be illustrated with available test results The International Program for the Evaluation of Short-Term Tests for Carcinogenicity[7] was a collaborative study undertaken by the UK Medical Research Council/Health and Safety Executive, the US National Institute of Environmental Health Sciences and Environmental Protection Agency, and the Japanese National Cancer Center Research Institute We were not involved in the study and gratefully acknowledge the assistance of the program organizers

Test chemicals were selected to include examples from the major classes of widely used organic compounds Based on previous animal bioassay results, the 42 chemicals shown in Table 1 were classified as 25 carcinogens and 17 noncarcinogens, including 14 structurally similar carcinogen–noncarcinogen pairs and 11 'problem carcinogens' (reported to be difficult or impossible to detect in standard bacterial mutation assays) The chemicals certainly do not represent a random sample of all chemicals or all widely used chemicals After changes in classification during testing, a final analysis was based on 38 chemicals, 26 carcinogens and 12 non-carcinogens Compared with the US Environmental Protection Agency's Gene-tox data base, this base has proportionally more non-carcinogens[18], it excludes fibres, heavy metals, and some other agents known to cause problems in short- or long-term bioassays

Thirty assay systems (Table 2) were selected to represent a wide variety of biological endpoints and mechanisms of action but cytogenetic methods may have been under-represented Some investigators were funded by the study, while other investigators financed their own testing The investigators were not informed of the identity of the chemicals until after submission of their results Results were reported as positive, negative, or inconclusive[7] Unfortunately, quantitative results and data on strength of evidence were generally not reported Of the chemicals in Table 1, four (*o*-toluidine hydrochloride, HMPA, safrole, DES) are included in the *in vitro* assays and another four (benzo(a)pyrene, pyrene, 2-acetylamino-fluorene, 4-acetylamino-fluorene) are being subjected to intensive *in vivo* assays in collaborative follow-up studies[18]

Statistical method

We begin by deriving an estimate of the probability that a chemical is carcinogenic from the results of the short-term tests We define the dependent variable as taking the value of 0 when the chemical is believed to be a noncarcinogen and a value of 1 when it is believed to be a carcinogen Each independent variable is the report of a test on the chemical, it assumes a value of 0 for negative test results and 1 for positive tests Inconclusive results and chemicals not tested are excluded from the analysis

The relationship between dependent variable (presumed carcinogenicity) and

Table 2 Test classification accuracy based on collaborative test results

Test number	Type of test	Cost* ($)	$N^\dagger$	Accuracy

* Estimated 1981 costs

† Number of chemicals tested in the international programme

independent variables is fitted to the testing results using logit analysis[19] The result is an estimated probability, P, that a chemical is carcinogenic If the analysis assigned $P=0$ to all noncarcinogens and $P=1$ to all carcinogens, the classification would be perfect With real data, a 'cut-point', P', is needed to classify all chemicals with $P<P'$ as noncarcinogens and all chemicals with $P>P'$ as carcinogens[20] As P' is increased, the number of FPs fall, but FNs appear The goal is to choose P' to minimize social costs $k\mathrm{FN}+\mathrm{FP}$, where k is the cost of an FN relative to that of an FP If the average social costs of FN and FP were identical ($k=1$), social cost would be minimized by having the smallest number of misclassifications However, if FN is valued higher than FP ($k=10$, as in Figs 1 and 2), then the cut-point is shifted to lower values (from B to A in Fig 2) In general P' is significantly greater than zero

In sum, the statistical procedure has two stages First, the probability of a chemical being a carcinogen is estimated by using observed short-term test results Second, a cut-point is sought that minimizes social cost in classifying chemicals

Reproducibility

Many of the short-term tests employed are relatively new and have not been standardized In the International Program, twelve investigators used versions of the *Salmonella*/microsome plate assay Eleven of the 38 chemicals were chosen because previous results in this type of assay system were unclear No two investigators reported identical results across the 38 chemicals, agreement between investigators ranging from 54% to 97%, even though the assay is standard Such discrepancies complicate interpretation and analysis[21,22]

Test batteries

Thirty short-term tests were examined in the International Program They comprise most (but certainly not all) of the short-term tests currently used or proposed for carcinogenicity testing Notably absent are DNA repair in cultured hepatocytes[23] and various bone marrow cytogenetic tests Every test was found to be of value in predicting carcinogenicity, with classification accuracies up to 81%, as shown in Table 2 Long-term bioassays may well offer no greater predictive accuracy, among 245 National Cancer Institute bioassays, 55 (22%) were judged inconclusive or equivocal[24]

While some tests show impressive

accuracy of classification, a battery of tests should be able to attain even greater accuracy, in large part because a variety of mechanisms can be screened Several proposals have been made concerning what combination would be best and these are discussed in Tables 2 and 3 Five previous proposals[25–28] as well as a set we drew from this data base are shown in Table 3 and the results of fitting the data to each test battery are shown in Table 4

Predicted probabilities of carcinogenicity for each of the 38 chemicals as estimated by test set 6 are shown in Fig 2 The estimated cut probability for $k=1$ would be between 0 42 and 0 81, for $k=10$, P' would be less than 0 05 The apparent superiority of test set 6 can be ascribed to our method of selecting tests These results indicate that test 21 (*Bacillus subtilis* Rec-assay) may deserve more attention than it has been given, despite current uncertainties about its mode of action

Value of testing

How much should society spend to acquire data before making a decision that a particular chemical should be treated as a potential carcinogen in humans? The more nearly complete and the more accurate the data, the lower the chance of an

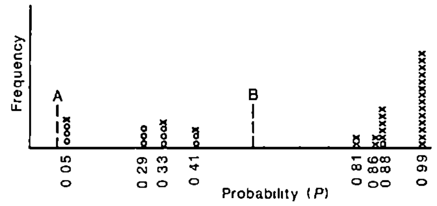

Fig 2 Predicted probability (P) of carcinogenicity This histogram for test set 6 shows the frequency of chemicals with P for the set of 38 chemicals in the International Collaborative Program Cut points corresponding to FN/FP values of 10(A) and 1(B) are indicated by dashed lines This cut point must be greater than zero to accommodate false positive test results × indicates a carcinogen while O indicates a noncarcinogen The three FN (from left to right) are chloroform, auramine, and DL-ethionine, the FP is α-butyrolactone

FN or FP The general principle is that data should be gathered until the time and dollar costs of acquiring more data approximate the additional savings to society from lowering the number of FP and FN Of course, the costs and savings are borne by different parties

The direct cost of additional data is the price of running more tests Each test has an associated accuracy and price Some tests are 'best buys' in the sense that no

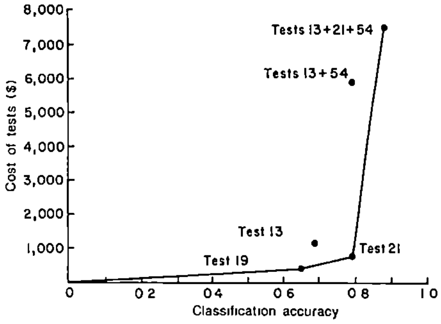

Fig. 3 Cost-effectiveness of *in vitro* testing The costs of tests are plotted against the estimate of test accuracy listed in Table 1 Tests 13, 21, and 54 correspond to set 6 in Table 2

test offers the same accuracy for a lower price Accuracy depends on the sample of chemicals tested Additional helpful tests give more information, especially when carcinogenic chemicals have heterogeneous mechanisms, but costs rise

The process of 'buying' additional classification accuracy can be represented schematically in Fig 3, where the vertical axis represents the cost of testing and the horizontal axis the classification accuracy of the tests in the International Program In this example, test 13 is both more expensive and less informative than test

Table 3 Test sets analysed

The short-term tests in Table 2 are grouped into five categories by the mechanisms tested From the 3 to 13 available assays that represented each category, we constructed a new battery (set 6) by choosing the tests whose results in the International Program data set had explained the highest proportion of variance in the dependent variable (presumptive carcinogenicity) For all batteries except set 3, at least one test had to be omitted

* Assays included in International Program, but tested on too few chemicals

† Assay not included in International Program

Table 4 Logit regression equations

	Test set equation	No of chemicals	R^2	χ^2	Predictive accuracy C	Predictive accuracy NC
1	$A=-3\ 1+3\ 1T_{13}+2\ 8T_{33}+2\ 8T_{54}$	29	51 9	17 3	4/9	20/20
2	$A=-4\ 0+3\ 4T_{13}+2\ 8T_{33}+1\ 8T_{42}+2\ 8T_{54}$	29	55 3	19 3	5/9	20/20
3 & 5	$A=-2\ 8+2\ 3T_{13}+2\ 6T_{42}+3\ 2T_{54}$	38	48 1	22 6	5/12	26/26
4	$A=-1\ 8+43\ 9T_{13}+-0\ 7T_{29}+2\ 3T_{54}$	30	44 7	9 6	6/9	20/21
6	$A=-3\ 1+2\ 2T_{13}+2\ 4T_{21}+2\ 7T_{54}$	38	56 2	22 9	11/12	23/26

The general logit equation is $P=1$, where P is the estimated probability that a chemical is a carcinogen and A is a linear equation of estimated coefficients multiplied by test results[17] For example, in set 6, A is calculated as −3 1 plus 2 2 times the result of test 13 (either 0 or 1) plus 2 4 times the result of test 21 (0 or 1) plus 2 7 times the result of test 54 (0 or 1) These coefficients are estimated to give the best fit between the dependent variable, presumptive carcinogenicity, and the P calculated from this logit equation The coefficient of test 54 (2 7) indicates that this test is more important in predicting carcinogenicity than the other two tests (coefficients 2 2 and 2 4) The omission of some chemicals from the data set and the relatively small size of the sample appear to have led to the nonsense result that test 29 in set 4 should be interpreted as the opposite of the test results R^2 should be interpreted as the proportion of the variation in the dependent variable accounted for by the regression, the χ^2 statistic shows that the test sets were all statistically significant Also shown are the proportions of carcinogens (C) and noncarcinogens (NC) (actually tested) that were classified correctly All the sets perform well, giving classification accuracies up to 89%, although the test batteries selected to be useful in predicting carcinogens are notably less successful in predicting noncarcinogens Test set 6 correctly predicts 10 of the 11 problem carcinogens known to be difficult for some of these tests to handle '

21 The combination of tests 13 and 54 gives more information at greater cost than 21 alone, the combination of tests 13, 21, and 54 provides more information at only a slight increase in cost The solid line shows the tests and combinations of tests that provide classification accuracy at lowest cost For this sample of chemicals, if only about $1,000 per chemical were available, test 21 would provide 79% classification accuracy If about $7,400 per chemical were available, tests 13, 21, and 54 could provide 89% classification accuracy

Because the classification accuracy of the various test batteries is about 90% and the total cost of testing 50,000 chemicals, with these batteries estimated at $8,000 per chemical, would be $400 million, our Fig 1 is not purely hypothetical It seems clear that society is making a serious mistake in failing to test most chemicals

Testing all chemicals immediately is neither feasible nor intelligent A better approach is a sequential testing policy with orderly selection of priority chemicals for testing (based on production, exposures, and structural similarity to known carcinogens) and use of information on metabolism and mechanisms of action to select tests and interpret results[29-32] Evaluation of initial test results will lead to modifications of the test regime and classification criteria Tier-testing systems can address inconclusive or conflicting results The above discussion is simplistic in dichotomizing chemicals as carcinogenic or harmless, rather than estimating the quantitative toxicity or potency, as testing becomes more sophisticated, it may be possible to estimate potential risks quantitatively

Conclusion

We have presented a decision analysis framework for the testing and classification of toxic chemicals, using an extraordinary set of published data The available set of tests and chemicals is small and difficult to interpret, but it is the best available and illustrates the framework The set of tests that together predicted the carcinogenicity of the 38 chemicals tested most successfully may not be appropriate for other chemicals, much less the entire population of 50,000 chemicals in use While the specific results strictly hold only for this limited data set, several general conclusions can be stated

First, short-term tests can be accurate predictors of the carcinogenicity of chemicals Sets of tests provided classification accuracy of 89% even when 11 of the 38 chemicals were known to be difficult to detect as mutagenic in the *Salmonella*/microsome assay

Second, decision analysis modelling of classification problems in terms of the social costs of false positives and false negatives can be instructive If the social costs are equal, classification accuracy should be maximized When the social costs of a false negative are greater than those of a false positive, the cut-point should be lowered to classify more chemicals with intermediate probability estimates as carcinogens

Finally, it may be cheaper for society to test all chemicals in common use with batteries of short-term tests, despite the resulting false positives and false negatives, rather than to continue tolerating thousands of unregulated carcinogens because there are no animal bioassay test results Several sets of short-term tests appear to be sufficiently accurate and inexpensive to warrant expanded use in testing However, a more intelligent procedure than routinely testing all 50,000 chemicals would be to test first the highest priority chemicals, based on production and exposures, and to evaluate the test batteries and classification criteria as testing progresses The US Environmental Protection Agency has authority under the Toxic Substances Control Act to demand a regime of tests for new chemicals that meet one of two Section 4 criteria (1) an unreasonable risk of injury to health or the environment based on its physical or biochemical characteristics, or (2) expected production in substantial quantities, giving rise to significant human or environmental exposures.

We recommend that the development and validation of short-term tests for application in screening new and existing chemicals should be accelerated

Introduction of homologous DNA sequences into mammalian cells induces mutations in the cognate gene

Kirk R. Thomas & Mario R. Capecchi

Department of Biology, University of Utah, Salt Lake City, Utah 84112, USA

Injection of homologous DNA sequences into nuclei of cultured mammalian cells induces mutations in the cognate chromosomal gene It appears that these mutations result from incorrect repair of a heteroduplex formed between the introduced and the chromosomal sequence This phenomenon is termed 'heteroduplex induced mutagenesis' The high frequency of these events suggests that this method may prove useful for introducing mutations into specific mammalian genes

GENE-TARGETING (homologous recombination between DNA sequences residing in the chromosome and newly introduced DNA sequences) allows the specific alteration of genes in the mammalian genome[1-4] Recently, Smithies *et al*[1] introduced a DNA sequence into the chromosomal β-globin locus by homologous recombination We have corrected mutant neomycin resistance genes (*neo*) in the host genome via homologous recombination with an injected plasmid DNA carrying a different mutation in the *neo* gene[2] In the process of analysing these gene-targeting events, we uncovered an unexpected class of 'corrected' chromosomal *neo*^{r} genes, which retained the original mutation but had acquired a second mutation that restored gene function The acquisition of the compensating mutation apparently occurred as a result of incorrect repair of a heteroduplex formed between the *neo* gene in the chromosome and the newly introduced *neo* gene These reactions occur at a surprisingly high frequency In addition, we show that the *neo*^{r} genes containing the compensating mutations function in mammalian cells and in *Escherischia coli* as a result of a novel translation reinitiation mechanism

Recombinant plasmids and recipient cell lines

We first established cell lines containing an amber mutant *neo* gene integrated into the genome of the mouse fibroblast line LMtk$^-$ We then corrected this mutation by injecting plasmid DNA carrying a non-overlapping deletion mutation in the *neo* gene Cell lines containing a corrected *neo*^{r} gene were identified by selecting for cells resistant to the drug G418

Figure 1*a* shows the recombinant plasmids, pRH4-14/TK and pRH140ΔNae/TK, used for these experiments These plasmids were derived from the parental plasmid pRH140[5], which contains sequences from the bacterial plasmid pBR322 and the *neo*^{r} gene coded by the bacterial Tn*5* transposon The pBR322 sequences supply an ampicillin resistance gene (*amp*^{r}) and an origin of DNA replication which functions in bacteria The *neo*^{r} gene was engineered to be functional both in bacteria and in mammalian cells[5] In bacteria, the *neo*^{r} gene confers kanamycin resistance, in mammalian cells the *neo*^{r} gene confers resistance to the drug G418 (G418^r) The herpes simplex virus thymidine kinase gene, HSV-*tk*, was introduced into the above plasmid at the unique *Bam*HI site to generate the plasmid pRH140/TK

pRH4-14/TK contains an amber codon near the 5′ end of the *neo* gene[5,6] This premature polypeptide chain termination signal renders the gene product defective in both bacteria and mammalian cells, the mutation also creates a new *Dde*I site which is used as a test for the presence of the amber mutation pRH140ΔNae/TK contains a deletion of 284 bp at the 3′ end of the *neo* gene which removes 52 amino acids from the carboxy-terminal end of the NEO protein, rendering it non-functional The plasmid pRH4-14-ΔNae/TK contains both the 4-14 amber mutation and the ΔNae deletion

We used two recipient mouse cell lines derived from LMtk$^-$ fibroblasts Both cell lines habour the plasmid pRH4-14/TK, but differ in the copy number and chromosomal location of the integrated plasmid[2] The cell line LM1 contains a single copy of the plasmid integrated into the host genome by its *Hin*dIII ends at a locus designated *J*-1 Cell line LM4 contains four copies of pRH-14/TK integrated at four independent chromosomal sites designated *J*-1-*J*-4

Generation of G418^r cell lines

Plasmid DNA, (~5 molecules per cell) was injected into nuclei of LM1 and LM4 cells, which were then selected with G418 Injection of linear pRH140ΔNae/TK molecules into LM1 or LM4 resulted in G418^r cell lines at a frequency of ~1 per 1,000 cells injected (Table 1) This frequency is five orders of magnitude greater than the spontaneous reversion frequency[2] (to G418^r of either cell line) No G418^r cell lines were obtained following injection of LM1 or LM4 with pBR322/TK, pRH4-

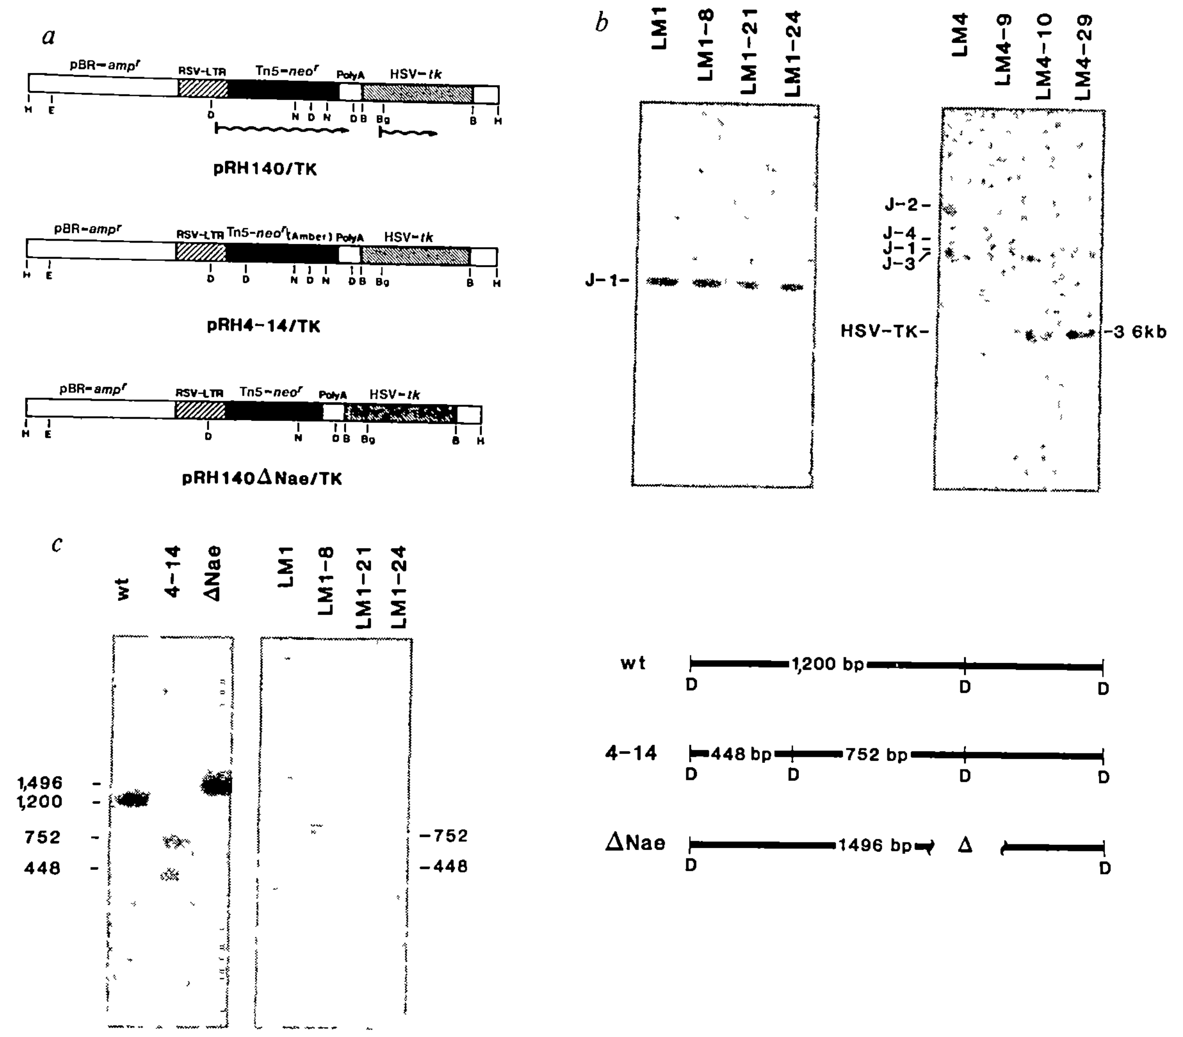

Fig 1 *a*, Maps of the plasmids pRH140/TK, pRH4-14/TK and pRH140ΔNae/TK *b*, *Bgl*II and *Bam*HI Southern transfer patterns of LM1, LM4 and their G418^r derivatives *c*, *Dde*I Southern transfer pattern of LM1, LM1-8, LM1-21 and LM1-24 *a*, The plasmids contain sequences derived from pBR322, the *neo*^{r} gene coded for by the bacterial Tn*5* transposon and the herpes simplex virus thymidine kinase gene (HSV-*tk*) The *neo*^{r} gene is expressed from a bifunctional promoter, RSV-LTR, which allows expression of the *neo*^{r} gene in *E coli* and in mammalian cells[5] pRH4-14/TK contains an amber mutation that also creates a new *Dde*I site pRH140ΔNae/TK contains a 284 base pair deletion at the 3′ end of the *neo* gene Each vector is represented in linear form from the unique *Hin*dIII site The restriction sites are designated H, *Hin*dIII, E, *Eco*RI, Bg, *Bgl*II, N, *Nae*I, B, *Bam*HI and D, *Dde*I Poly A, polyadenylation sequence from HSV-*tk*. For a more extensive restriction map of these plasmids see refs 2, 6 *b*, DNA was purified from each cell line and digested with either *Bgl*II (LM1, LM1-8, LM1-21, LM1-24) or *Bam*HI (LM4, LM4-9, LM4-10, LM4-29) Aliquots of DNA (5 μg) were electrophoresed through 0 75% agarose, transferred to nitrocellulose paper and probed with either ^{32}P labelled, nick-translated pRH140 (LM1) or pRH140/TK (LM4) kb, kilobases *c*, DNA (10 μg) from each cell line was digested with *Dde*I, electrophoresed through 0 75% agarose, transferred to nitrocellulose and probed with a ^{32}P-labelled, nick-translated, 1200-bp *Dde*I fragment from the *neo*^{r} gene of pRH140 The sizes (in base pairs) of restriction fragments generated by *Dde*I digestion of the three *neo*^{r} alleles (wild type, the 4-14 amber mutation and the ΔNae deletion mutation) are given

14/TK or pRH-14-ΔNae/TK (see Table 1)

Two classes of G418^r cell lines were obtained from LM1 and LM4 In the first class a wild type *neo*^{r} gene was generated by homologous recombination between the newly introduced pRH140ΔNae/TK plasmid sequence and the pRH4-14/TK chromosomal sequence This class has been described previously[2] The second class became resistant to G418^r by virtue of 'heteroduplex induced (het-induced) mutagenesis'

Fig 1*b* shows the Southern transfer patterns of LM1 and LM4 and several of their G418 derivatives Digestion of genomic DNA with either *Bam*HI or *Bgl*II will isolate the integrated *neo* genes onto single fragments linked to chromosomal sequences In the case of LM1, *Bgl*II digestion reveals a single hybridizing band representing the single *neo* locus, *J*-1 The *Bgl*II Southern transfer patterns of the G418^r derivative cell lines LM1-8, LM1-21 and LM1-24, are indistinguishable from the parental pattern Digestion of LM4 DNA with *Bam*HI reveals 4 bands which hybridize to pRH140 sequences *Bam*HI digestion of DNA from the G418^r derivatives LM4-9, LM4-10 and LM4-29 show identical patterns Thus conversion to G418^r was not the result of acquisition of new *neo* sequences or rearrangements of old ones

As shown in Fig 1*c*, digestion of genomic DNA with the restriction enzyme *Dde*I generates a series of fragments that allow the detection of the wild-type *neo*^{r} gene and each of the *neo* mutant alleles, the 4-14 amber mutation and the ΔNae deletion mutation The Southern transfer patterns of three G418^r cell lines derived from LM1 following digestion of genomic DNA with *Dde*I are also shown Only the *Dde*I fragments characteristic of the 4-14 amber mutation are seen Similar results were obtained when DNA from LM4 and its derivative G418^r cell lines, LM4-9, LM4-10 and LM4-29 were digested with *Dde*I These results were quite unexpected because all the derivative cell lines were G418^r

Fig 2 A summary of pertinent DNA sequences from plasmids rescued from LM1 and LM4 and their G418^r derivatives Plasmids were rescued from each cell line as described[2] 5′ fragments of the *neo*^{r} genes from these plasmids were subcloned into the M13 vector, mp8, and sequenced by the chain termination method[8] The sequences of the protein coding strands representing codons 12–22 are shown The amber mutations as well as the 6 base pair repeats are underlined

Plasmids were rescued from the genome of LM1, LM1-8, LM1-21 and LM1-24 For these experiments genomic DNA was digested with *Bam*HI or *Bgl*II and ligated under conditions that favoured intramolecular ligation This DNA was used to obtain ampicillin resistant bacteria by transfection[6] From each cell line we rescued a class of plasmids containing the same 5′ junction with chromosomal DNA Plasmids derived from LM1, as expected, do not provide resistance to kanamycin, but the plasmids rescued from the G418^r cell lines do When we examined the *Dde*I polymorphism present in these rescued plasmids, all had the 4–14 *Dde*I polymorphism including the plasmids rescued from LM1-8, LM1-21 and LM1-24 Thus all the plasmids retained the amber mutation, yet those rescued from the G418^r cell lines conferred kanamycin resistance on bacteria

Plasmids were also rescued from LM4, LM4-9, LM4-10 and LM4-29 after digestion of genomic DNA with either *Bam*HI or *Bgl*II One plasmid from each G418r line was found to confer kanamycin resistance on *E coli* When these plasmids were reintroduced into LMtk$^-$ cells G418^r colonies were obtained at a frequency similar to that resulting from injection of the wild-type *neo*^{r} gene Thus these plasmids contain a *neo*^{r} gene that functions in both bacteria and mammalian cells The rescued plasmids all had the 4-14 *Dde*I polymorphism, including those that conferred drug resistance (*J*-1 from LM4-9 and LM4-10 and *J*-4 from LM4-29)

Table 1 Transformation frequencies to G418^r by injecting LM1 and LM4 cells with plasmid DNAs

DNA injected	Frequency of G418^r cell lines generated by hetero-duplex induced mutagenesis	Number of cells injected
pBR/TK	0	2×10^4
pRH140ΔNae/TK	$1\ 2\times10^{-3}$	10^4
pRH4-14/TK	0	3×10^4
pRH4-14-ΔNae/TK	0	2×10^4

LM1 or LM4 cells were grown on glass cover slips (10 mm × 10 mm) in 35 mm Petri dishes Twenty-five cells per dish received nuclear injections of ~5 plasmid molecules per cell[7] Plasmid molecules were linearized with *Hin*dIII (pBR/TK) or *Bcl*I (pRH140ΔNae/TK, pRH-14/TK, pRH4-14-ΔNae/TK) After the injection, the cells were incubated for 24 h in nonselective medium at 37° in a 5% CO_2 incubator and then switched to minimum essential medium supplemented with 400 μg ml^{-1} G418 The dishes were scored for colonies after 3 weeks pBR/TK contains the 3 6 kb *Bam*HI fragment of the herpes *tk* gene inserted at the *Bam*HI site of pBR322 pRH4-14/TK and pRH140ΔNae/TK are described in Fig 1 legend pRH4-14-ΔNae/TK was created by the deletion of the 284 bp *Nae* fragment from the *neo*^{r} gene in pRH4-14/TK

Fig 3 The amino-terminal sequences of wild-type and pseudo-wild-type *neo*^{r} proteins are shown with the DNA sequence of the 5′ end of the *neo*^{r} gene To facilitate protein purification, hybrid proteins were made by in-frame fusions of the 5′ ends of *neo*^{r} genes with the *lacZ* gene Wild-type fusions were made with the *neo*^{r} gene from the plasmid *p*RH140 (ref 5), pseudo-wild-type fusions were made with the *neo*^{r} gene from pLM1-1-J1 Both fusions were constructed by inserting a blunt-ended *Bcl*I–*Pvu*II restriction fragment, containing nucleotides −31 to +233 of *neo*^{r}, into a blunt-ended *Apa*I site in the 8th codon of the *lacZ* gene in p93 94 (R Weiss, unpublished) *E coli* cells containing the hybrid genes were grown to stationary phase, lysed in a French Press, and the extract clarified by centrifugation at 280,000*g* for one h The β-galactosidase activity was purified either by adhesion to antibodies (mouse anti- β-galactosidase, Promega Biotech), followed by acrylamide gel electrophoresis, or by affinity chromatography[9] The sequence of the first seven amino acids of each protein was determined on an ABI microprotein sequenator

The compensating mutations are insertions

We sequenced ~300 bp at the 5′ ends of the *neo*^{r} genes isolated from the G418^r cell lines These were compared with the corresponding sequences from the plasmids isolated from the parental cell lines LM1 and LM4 As illustrated in Fig 2, the only changes found in the *neo*^{r} genes were the insertion of a thymidine residue 11 bp downstream from the amber mutation in pLM1-8-J1 and pLM4-9-J1, the insertion of four bases, GGCT, in pLM1-1-J1, pLM1-21-J1, pLM1-24-J1, pLM4-10-J1 and pLM4-29-J4, and the insertion of a guanosine residue 8 or 9 bp downstream from the amber mutation in pLM1-36-J1

Reinitiation of translation

To determine how *neo*^{r} genes containing both an amber mutation and a frameshift mutation confer *neo*^{r} activity in both bacteria and mammalian cells, we analysed the amino-terminal sequence of the *neo*^{r} gene products We will refer to the gene containing both the amber mutation and an insertion mutation as the pseudo-wild-type gene To facilitate analysis, the 5′ 200 nucleotides of the *neo* genes were fused to the *lacZ* gene Hybrid β-galactosidase containing the amino termini from the wild-type and pseudo-wild-type NEO protein containing the amber mutation and the GGCT insertion were purified from transformed *E coli* and subjected to amino-terminal sequencing The fusion protein from wild-type *neo*^{r}-*lacZ* gene has the sequence Met-Ile-Glu-Gln-Asp-Gly as predicted (Fig 3) However, the protein from the pseudo-wild-type *lacZ* gene fusion began with the sequence Met-Asp-Cys-Thr-Gln This protein was initiated from an AUG codon 14 bp downstream from the normal AUG codon in the −1 translation reading frame (see Fig 3) It now becomes clear how the insertion mutations reverse the amber mutation After initiation of protein synthesis in the −1 frame, the ribosome passes through the amber mutation, which is in the 0 reading frame and therefore not read, and regains proper phase when it reaches the +1 frameshift mutation (insertion of a T, G or GGCT) Although this alters the amino-terminal amino acid sequence of the NEO protein, this portion of the protein has been shown to be dispensable[10]

Figure 4*a* shows two models that could explain how translation of the pseudo-wild-type gene begins at the −1 AUG codon

In model I we assume that the ribosome can enter at two sites, AUG codons in the 0 and −1 reading frame Model II uses a single entry point followed by translation reinitiation In this model the ribosome enters at the AUG codon in the 0 reading frame and translates the messenger RNA until it reaches the amber codon There it terminates and releases the polypeptide fragment The ribosome then scans back until it reaches the −1 AUG codon, where it reinitiates protein synthesis

We performed two sets of experiments to distinguish between these models First, the amber mutation was removed, by *in vitro* site-directed mutagenesis, from the pseudo-wild-type gene Second, a four bp insertion mutation was created *in vitro* in the wild-type *neo*^{r} gene just downstream from the −1 AUG codon Plasmids containing these altered pseudo-wild-type and wild-type genes were introduced into *E coli* and cultured mammalian cells to evaluate their ability to confer kanamycin and G418 resistance (see Fig 4*b*) The two models make opposite predictions of the resultant phenotypes If the ribosome can enter at either AUG then both the above plasmids should be functional, the ribosomes entering at the −1 AUG codon would regain proper phase on reaching either of the +1 frameshift mutations However, neither set of plasmids would be functional if only the initial entry site is used because (1) after entering the pseudo-wild-type mRNA lacking the amber mutation, the ribosome would be unable to terminate and therefore unable to reinitiate protein synthesis, (2) after entering a wild type mRNA containing a four base-pair insertion, the ribosome would encounter a +1 frameshift and generate a mutant gene product As shown in Fig 4*b*, neither of these *neo* genes is functional in either bacteria or mammalian cells These results strongly support the single entry-termination-reinitiation model

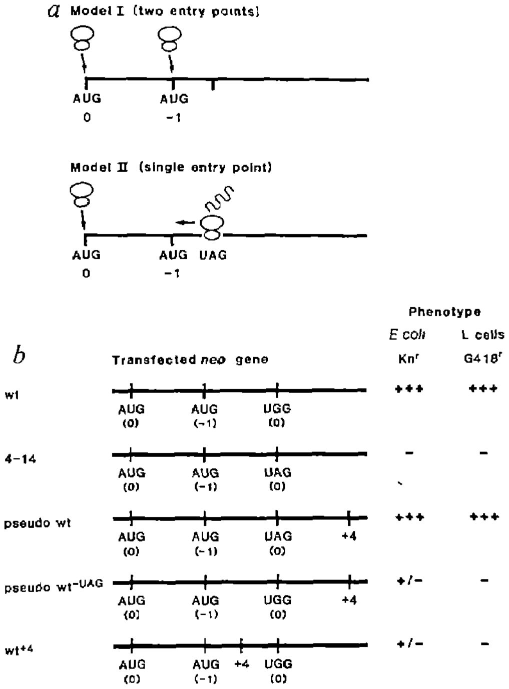

Fig 4 *a* Two models explaining the synthesis of pseudo-wild-type protein *b*, Phenotypic analysis of transfected *neo*^{r} genes *a*, In model I, ribosomes entering *neo*^{r} messenger RNA bind at two binding sites, one on the 0 reading frame at nucleotide 1, the other on the −1 reading frame at nucleotide 14 Proteins made from the latter site would be shifted onto the appropriate reading frame by downstream +1 frameshifts Model II proposes a single ribosome entry site in the 0 reading frame at nucleotide 1 To use the −1 AUG codon at position 14, the ribosome must first translate in the 0 reading frame up to the UAG (amber) codon At this point, the ribosome will release the newly synthesized peptide and then scan the message until it locates the alternative AUG codon in the −1 reading frame *b*, Plasmids containing various *neo*^{r} genes were assayed for the ability to confer drug resistance to *E coli* or to mouse L cells The wild type *neo*^{r} gene (wt) from pRH140 contains a tryptophan codon, UGG, at codon 15 4–14 is the amber mutation from the plasmid pRH4–14 and contains UAG at codon 15 Pseudo-wt is a sequence containing both the 4-14 amber mutation and a downstream, four base-pair insertion of GGCT, following nucleotide 56 Pseudo-wt$^{(-UAG)}$ was derived from the pseudo-wt gene, by removal of the UAG codon by site-directed mutagenesis[11] The mutant wt^{+4} was derived from the wild-type gene following the insertion of four base pairs at position 35 GGCC was inserted at this position by filling in the ends of an *Xma*III restriction site The figure depicts the 5′ end of the *neo*^{r} mRNA from each plasmid AUG (0), the translational initiation codon in the 0 reading frame, AUG (−1), the proposed initiation codon in the −1 reading frame at nucleotide 14, the sites of insertional mutagenesis of GGCC following base 35 or GGCT following base 56 are indicated (+4), UGG and UAG are the alternative states of the fifteenth codon Plasmids containing these mutations were introduced into *E coli* strain MH1 by CaCl$_2$-mediated transformation or into mouse L cells by nuclear microinjection Sensitivity of *E coli* to kanamycin or of L cells to G418, was determined as previously described[6] +/−, Resistance to low levels of kanamycin We believe that this low level of resistance was again due to reinitiation of the −1 AUG as these +1 frameshift mutations generate a new nonsense mutation in the +1 reading frame much further downstream from the − AUG (a UGA codon 53 bp downstream from the −1 AUG codon)

Discussion

The unexpected finding that correction of the pRH4–14/TK sequences in the host genome of LM1 and LM4 often results from insertion of a few base pairs downstream from the amber mutation raises a number of questions How did the insertions of these base pairs occur? How did injection of pRH140ΔNae/TK into either LM1 or LM4 mediate these events? The DNA sequence surrounding the position of the base-pair insertions contains the six bp direct repeat GGCTAT (see Fig 2) The fact that each of the insertions, T, G or GGCT is a tandem repeat of part of this sequence suggests a duplication-generating mechanism

A number of observations argue that the insertion or duplication events at this site were induced by the initiation of recombination between the pRH4–14/TK sequence residing in the chromosome and the incoming pRH140ΔNae/TK sequence First, the frequency of generating this class of G418^r cell lines was comparable to the frequency of generating cell lines by legitimate gene replacement or gene conversion[2] Second, this frequency is five orders of magnitude greater than the spontaneous reversion frequency of LM1 or LM4 to G418^r Third, we previously isolated a cell line in which both a homologous recombination event and a het-induced mutagenic event occurred[2] Because the homologous recombination events and the mutagenic events each occur at a frequency of ~1 per 1000 cells injected, the predicted frequency of both events occurring independently in the same cell line is 1 per 10^6 injected cells As we obtained such a cell line after a few thousand injections, it is tempting to postulate that the two events occurred as a result of a concerted reaction Fourth, we did not obtain G418^r cells from LM1 or LM4 following injection of a plasmid DNA, pBR322/TK, that does not contain sequences similar to the *neo* gene, so injection of DNA does not *per se* induce rampant mutagenesis Similarly, we did not obtain G418^r cells from LM1 or LM4 following injection of pRH4–14/TK or pRH4–14ΔNae/TK These experiments demonstrate the specificity of the reaction Because injection of the pRH4–14/TK vector does not induce the mutations, an important factor for triggering the mutagenic response may be the single base-pair mismatches at the amber mutation and/or the large mismatch at the ΔNae deletion The observation that injection of the double mutant, pRH4-14-ΔNae/TK, also does not induce mutations argues that at least the single base-pair mismatch is required The only mechanism that we can envision by which single base-pair mismatches between a chromosomal sequence and an exogeneous sequence can influence the mutation process requires formation of a heteroduplex

A number of models can be drawn in which the strands in the heteroduplex transiently misalign at the direct repeats leading to partial duplication of this sequence as a consequence of DNA repair A model mechanism for the insertions found in the LM1 and LM4 G418^r cell lines is given in Fig 5 A misaligned heteroduplex between the *neo* gene in the chromosome and the injected *neo* gene is formed, a nick is then introduced near one of the loops, generating a primer for strand extension The condition that the insertion mutation produces a functional gene restricts both the position of the nicks and the number of nucleotides that can be incorporated at the nick We have shown that insertions that generate a frameshift mutation in the +1 translation reading frame will compensate for the upstream amber mutation This condition limits the number of bases incorporated at the nick to one base, 4 bases, 7 bases etc The position of the nicks is also restricted Nicks at some positions followed by insertion of one or four bp introduce new nonsense mutations Thus, only a limited set of possible mutations exist which generate a functional *neo*^{r} gene After primer extension, the DNA strands are ligated and the insertion fixed into the genome by a round of DNA replication In prokaryotic recombination and/or DNA repair, reactions homologous to the ligation depicted in the model may not occur, however, such reactions do occur in mammalian cells[12]

We stress that all the insertion mutations that we analysed resulted from independent events They involve insertions of different bases, in different cell lines, at different chromosomal loci and were generated at different times It is interesting that all eight insertions occurred in the first repeat The proximity and/or the nature of the mismatch at the amber mutation may account for this polarity

The translation reinitiation mechanism described in this paper could be a general mechanism for translating polycistronic messenger RNAs in eukaryotic cells After the termination of the first protein, the ribosome could scan, forward or backwards, for the AUG codon used to initiate translation of the second protein Recent reports[13,14] support such a model for translation of a polycistronic messenger Further, the *src* mRNA of the Rous sarcoma virus and some genes of the cauliflower mosaic virus may be translated by such a mechanism[15,16] A similar mechanism can also explain the observation[17,18] made with *in vitro* engineered templates, that translation-initiation at an internal AUG codon is stimulated by the presence of a termination codon in frame with the upstream AUG codon

Conclusion

As a consequence of correcting a gene residing in the host genome by 'gene-targeting', we uncovered an unexpected class of corrected genes These genes still retained the original mutation but acquired a compensating mutation The frequency of this event was surprising and was shown to depend not only on homology but also on mismatched base pairs between the newly introduced DNA sequence and the corresponding sequence residing in the genome All the insertion mutations occurred in a small direct repeat proximal to the base-pair mismatch, suggesting that the direct repeat is also an important component for generating high frequency 'het-induced mutagenesis' The actual frequency of mutagenesis may be much higher than the observed frequency of 1 per 1000 cells receiving an injection because we imposed the condition that only mutations that converted the amber mutant into a functional gene will be identified Most such mutations would not be expected to restore gene activity

Fig. 5 A model for the mechanism of inserting GGCT into the chromosomal pRH-14/TK sequence The first step features the formation of a misaligned heteroduplex at the six base-pair direct repeat, between the *neo*^{r} gene in the chromosome and the injected *neo*^{r} gene In the second step a nick is introduced near one of the displaced loops to generate a primer for strand extension Following extension, the strands are ligated and the insertion fixed into the genome by a round of DNA replication The positions of the nicks were chosen to account for the insertions isolated nick 1 would generate either the +T or the +GGCT insertions, nick 2 would generate the +G insertion The site of the nick and the length of strand extension is limited by the requirement to produce a functional gene Bold letters, the bases involved in the six base-pair repeats, *, the bases added during strand extension

In future, we will examine 'het-induced mutagenesis' that directs the loss of gene function rather than the correction of gene function These events should occur at a higher frequency and reveal a wider spectrum of changes at the DNA sequence level The only apparent requirements for a 'hot spot' for het-induced mutagenesis are small direct repeats proximal to base-pair mismatches between the newly introduced plasmid sequence and the homologous sequence in the genome Comparable small direct repeats are encountered in the DNA coding sequence of most genes, making them susceptible to this type of mutagenesis Permutations of this methodology should provide the means for efficiently introducing mutations into specific mammalian cellular genes

We thank Laurie Fraser for assistance with tissue culture and Regina Zeikus, Robert Weiss and Diane Dunn for assistance with protein sequencing

Outbursts of Cygnus X-3 observed at 1.3 and 3.3 mm wavelengths

J. W. M. Baars*, W. J. Altenhoff*, H. Hein† & H. Steppe†

* Max-Planck-Institut fur Radioastronomie, D-5300 Bonn 1, FRG
† Instituto de Radioastronomia Millimetrica, Aven divina Pastora 7, 18012, Granada, Spain

The X-ray source Cyg X-3 is associated with a radio source which shows irregular, fast and extremely strong outbursts of radiation. The first such event was seen in September 1972 by many observers over a wide frequency range[1]; several more events have occurred since then. The main characteristics of the outbursts have been described by the behaviour of an expanding synchrotron source, which undergoes adiabatic and synchrotron losses[1,8]. However, the detailed physics of the outbursts remains to be understood, in spite of a growing set of observational data. Here we report observations of Cyg X-3 made simultaneously at wavelengths of 1.3 and 3.3 mm, showing outbursts with an intensity of several Janskys and a duration of only a few hours.

Cyg X-3 is a binary object with a 4.8-h periodicity in both X-ray and infrared emission[10]. This periodicity may also be visible in low-level radio flares[2], but was not observed in several outbursts at a level above 50 mJy (ref. 3). Following a suggestion by K. Johnston that a flare was imminent, we included Cyg X-3 as a test object for continuum observations, during the commissioning of the new 30-m-diameter Millimetre Radio Telescope[4] of the French–German Institute for Radioastronomy in the Millimetre Range (IRAM).

Apart from an observation during the September 1972 outburst at 3.3 mm (ref. 5), no data are available on the development of a burst at millimetre wavelengths. Our observations made simultaneously at two wavelengths (1.3 and 3.3 mm) enable us to study the time dependence of the spectral index. We observed Cyg X-3 from 1 to 11 October 1985. On 1/2 October we barely detected Cyg X-3, whereas on 5/6 October it was easily seen. Subsequently, we followed the object on two consecutive days, from 17.00 UT on 6 October until 02.00 UT on 7 October, and from 16.00 UT on 7 October until 02.45 UT on 8 October. On 11 October a single observation at 3.3 mm was obtained.

The IRAM 30-m telescope is located at 2,850 m altitude on Pico Veleta in the Sierra Nevada near Granada, Spain. The telescope has an altazimuth mounting with a Nasmyth focus in a spacious instrument cabin. During our observations, the beams of the two receivers were coincident to within 2 arc s on the sky. The receivers were equipped with cooled Schottky-mixers and had a double-sideband system temperature (excluding noise from the antenna and the atmosphere) of 360 K and 200 K at the wavelengths of 1.3 and 3.3 mm (frequencies of 226 and 90 GHz), respectively, and a bandwidth of 500 MHz. Calibration of the system sensitivity is achieved with the aid of loads at ambient and liquid-nitrogen temperatures, introduced in the plane between the quaternary Nasmyth mirror and the receiver input.

At millimetre wavelengths the sensitivity is usually limited by fluctuations in the lower atmosphere. These can be effectively suppressed by quickly moving the antenna beam on and off the source and measuring the difference in the signal received from the two directions. In the lower region of the atmosphere, the two beams have an almost perfect overlap, so that the fluctuations are nearly cancelled in the difference signal[6].

For these 'beam-switched' observations we installed a focal-plane chopper. A vane in the form of a butterfly with a diameter of 1.5 m, rotated parallel to and in front of the quaternary mirror, moved the beam through an angle of 82 arc s on the sky at a rate of 6 Hz. Excellent suppression of atmospheric fluctuations was achieved. The half-power width of the antenna beam is 26 arc s at 3.3 mm wavelength and 12.3 arc s at 1.3 mm, and during our observing period, the aperture efficiencies at these wavelengths were 0.53 and 0.24, respectively.

Our method of observation consisted of measuring the ratio of the intensities of Cyg X-3 and the planetary nebula NGC7027. The angular distance between these two sources is only a few degrees, so that any dependence on the atmospheric extinction and antenna efficiency is eliminated from the ratio. NGC7027 is strong enough to be used for measuring pointing corrections, and, moreover, does not show any time variations in its flux density. We used Mars as a flux density calibrator. On 9 November 1985 we determined the ratio NGC7027/Mars, when Mars was near aphelion and had an apparent diameter of 4.04 arc s. We assumed a black-body brightness temperature of 198 K with an absolute error of probably <5% (ref. 7), and derived flux densities of 93.8 and 14.9 Jy, leading to observed peak flux densities for NGC7027 of 4.27 and 4.80 Jy at 1.3 and 3.3 mm, respectively.

Following a pointing check on NGC7027, its intensity was determined by a set of five on-off pairs, in which the on- and off-axis beams were alternately placed on the source for an integration time of 10 s each. Then a similar set of ten on-off pairs was obtained for Cyg X-3. Such a cycle lasted for 30 min, after which it was repeated.

Figure 1 shows the derived flux densities of Cyg X-3 as a function of time. The noise in a set of ten on-off measurements (200 s of integration time) is ~0.1–0.2 and 0.04 Jy at 1.3 and

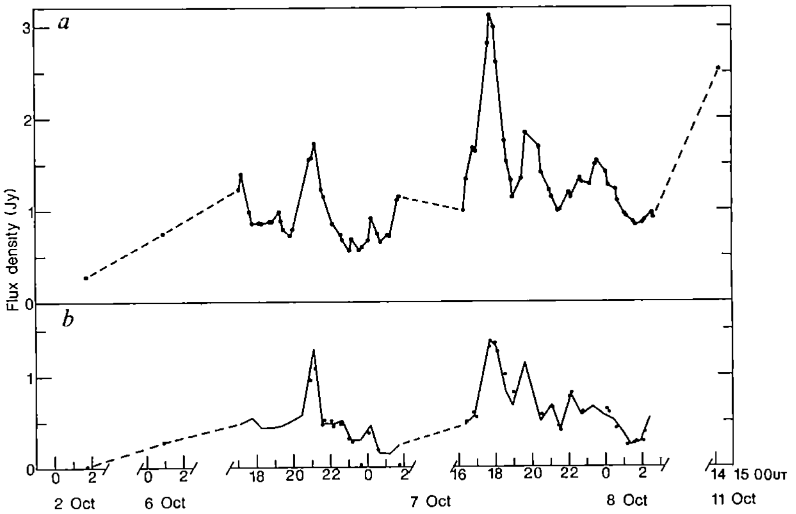

Fig. 1 Flux density of Cyg X-3 during 2–11 October 1985 at wavelengths of 3.3 (*a*) and 1.3 (*b*) mm, observed with the IRAM 30-m telescope. In *b* the line connects the averages of two adjacent measurements, which are shown individually as dots.

3 3 mm, respectively By combining pairs of data points the 1 3 mm results were smoothed considerably

During our observations three strong outbursts occurred almost simultaneously at both wavelengths The first and last are nearly equally strong at both frequencies (spectral index $\alpha = -0\ 2$, where $S \propto \nu^{\alpha}$ for flux density S and frequency ν), whereas the middle outburst is twice as strong at 3 3 mm ($\alpha = -0\ 7$) The average plateau-level flux density also has $\alpha = -0\ 7$ on both days

During the observation period the flux density of Cyg X-3 was monitored at 11 cm wavelength with the Green Bank interferometer (K. J Johnston, personal communication) Our first observation on 1/2 October coincides with the beginning of the precursor burst at 11 cm, and the main flare at 11 cm rose from 2 0 Jy at 00 00 UT on 6 October to 9 0 Jy at 00 00 UT on 8 October Our millimetre-wavelength observations show only a slow increase of the plateau level during this interval

The time development of the 11 cm flare is similar to earlier outbursts observed at wavelengths between 2 and 21 cm The first widely observed flare of September 1972 has been well described by a model of an expanding cloud of relativistic particles, mixed with an ionized thermal gas[8], in which the flare reaches its maximum earlier at shorter wavelengths

This model is clearly not appropriate for the character of the flare at millimetre wavelengths The duration of the millimetre-wavelength bursts is only ~1 h between the half-power points, with a suggestion of a broadening at 3 3 mm This could explain why these single, short outbursts are not seen at the longer centimetre wavelengths

The millimetre-wavelength bursts are probably related to a repeated injection of relativistic particles Such a scheme is necessary to adequately describe the early phase of the centimetre-wavelength flares[9] At injection the electrons will have the highest energy, and in losing their energy during the expansion, they will radiate first at the shortest wavelengths The millimetre-wavelength flares of short duration may be manifestations of separate bursts of injected particles, in which case differences in the optical depth of the medium could cause the observed differences in spectral index To understand how these short bursts build up to the observed centimetre-wavelength flare will require the analysis of detailed, simultaneous observations at millimetre and short centimetre wavelengths

We have looked in these data for the 4 8-h periodicity present in the X-ray and infrared emission of Cyg X-3 A spectral analysis indicates a possible periodicity of ~5 h in the 3 3-mm data on 6/7 October, which can be seen also in Fig 1 There is a suggestion of a 2 5-h periodicity in the 1 3-mm data on 7/8 October Because our observations on 7 October started almost exactly 3×4 8 h after we stopped observing on 6/7 October, we also combined the data and searched the total 20 h of data for a 4 8-h periodicity without finding a significant result We conclude that our data do not produce evidence for a 4 8-h periodicity in the millimetre-wavelength outbursts on 6–8 October 1985, similar to the result in ref 3 for centimetre-wavelength outbursts above 50 mJy Our noise level is too high to detect a possible periodicity in the low-level radiation[2]

We thank K J Johnston for a timely warning of a possible outburst and for data before publication The observation on 11 October was made by A Baudry

Io plasma torus and the source of jovian kilometric radiation (bKOM)

Dyfrig Jones

Space Plasma Physics Group, British Antarctic Survey, NERC,
Madingley Road, Cambridge CB3 0ET, UK

One of the many discoveries by Voyagers 1 and 2 during their flyby of Jupiter was the detection of radio emission at kilometric wavelengths[1,2] in the frequency range 20–500 kHz. Broadband jovian kilometric radiation bKOM was observed to be beamed away from the zenomagnetic equatorial plane, the beaming angle increasing with increasing frequency[1–3]. It was suggested that bKOM is created by the linear conversion of electrostatic upper hybrid waves to electromagnetic waves in the density gradients at the Io torus[4]. The beaming is inherent to the conversion mechanism and depends on the characteristic frequencies of the source plasma Here I present results, based on this theory, of remote sensing of the Io torus using bKOM observed by Voyager 2 when inbound towards Jupiter. The density profiles obtained are in remarkable agreement with measurements of the torus densities obtained *in situ* by Voyager 1. This seems to provide very strong evidence that bKOM is produced at the Io torus by the linear mode-conversion mechanism and indicates that the technique used for remote sensing could be a powerful method of determining the torus characteristics when no *in situ* measurements are available.

bKOM first appeared in the planetary radio astronomy (PRA) data when Voyagers were >2 AU from the planet[1,2] Figure 1 shows a PRA wave spectrogram[5] in which bKOM is the tapered emission recorded when Jupiter's north magnetic pole (located at central meridian longitude, CML = 202°) is tilted towards the spacecraft The leading edges of the tapered emissions occur when Voyager 2 is at CML <202° and the trailing edges when Voyager's CML is >202° Voyager 2's jovicentric latitude when inbound (at 09 30 h jovian local time, LT), was 7 2° and, because Jupiter's magnetic dipole axis is tilted at 9 6° to its rotation axis, the spacecraft's excursion in magnetic latitude during one jovian rotation was −2 4° to 16 8° Spectrograms such as that in Fig 1 show that bKOM was generally observed when Voyager was at magnetic latitudes >10 °N Voyager 1, whose magnetic latitude varied between −6 5° and 12 7° when inbound (at 10 30 LT), and which therefore went to more southerly latitudes than Voyager 2, occasionally observed a similar beaming in the southern hemisphere[6] This would indicate approximate symmetry about the magnetic equator with a wedge-shaped region of no illumination near the equatorial plane, the width of the region depending on frequency Contrary to earlier reports[5] the radiation is right-hand polarized in the northern hemisphere and left-hand polarized in the south[6] The tapered form of the emisson evident in Fig 1 clearly shows that the higher frequencies are beamed to higher latitudes

The linear conversion theory[4] proposed for the production of bKOM invoked electrostatic upper hybrid (ESUH) waves as the source, with their propagation in the Io plasma torus ultimately resulting in the emission of the electromagnetic O mode radiation Intense ESUH waves were observed within 23 R_J of the planet which were confined to within 1 9° of the magnetic equatorial plane[7] In the theory, it is proposed that these waves propagate in the torus density gradient which is assumed to be normal to the magnetic field The ESUH waves first become electromagnetic Z mode waves[8] which, in turn, after further propagation, convert into electromagnetic O mode radiation through a radio window[9] which exists where the wave frequency equals the plasma frequency $f_p = 9 \times 10^{-3} N_e^{1/2}$ kHz, N_e m^{-3} being the electron density On passing through the radio window into the low-density region outside the torus the O mode radiation emanates as two beams at angle $\beta = \arctan\ (f_p/f_c)^{1/2}$ to

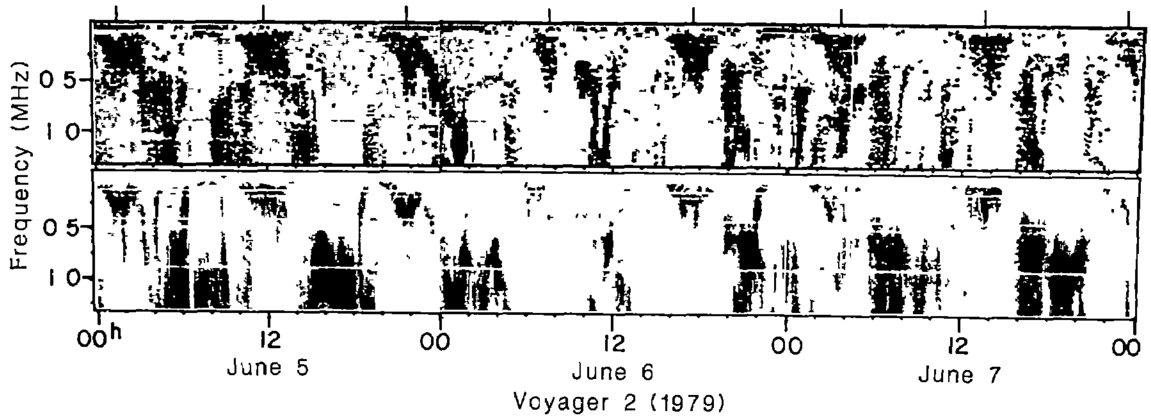

Fig. 1 Voyager 2 spectrogram[5] of jovian radio emissions in the range 20 kHz–1.3 MHz. Total power is shown in bottom panel, increasing darkness being proportional to increasing intensity. Upper panel shows polarization information on the same emissions. In the 72-h period shown, eight consecutive bKOM events are visible as the V shaped emissions extending up to ~500–600 kHz and coincident with the north dipole tip passage: their polarization is right-handed[6]. The events are anticoincident with the hectometric radiation seen at higher frequencies.

the magnetic field line[4], $f_c = 0.028\ B$ kHz being the electron cyclotron frequency for a magnetic field strength of B nT. Thus for a source at the equatorial plane in a dipole magnetic field, the radiation is beamed at angles $\alpha = (\pi/2 - \beta)$ to the equatorial plane, one beam to the north and one to the south. If the emitting region is distributed about the equatorial plane by ~±2° as would be the case if the jovian ESUH waves are the source, then the southern edge of the northern beam would be expected to derive from the most southerly source, that is from −2° magnetic latitude. Typical ray paths derived from ray-tracing calculations in a realistic Io torus model which clearly illustrate this configuration have been presented in Fig. 2 of ref. 10, a simplified sketch is included here in Fig. 2. Had Voyager's excursions in latitude about the equatorial plane been greater, then, according to the theory, they would have observed the high-latitude edges of the beams which, in the case of the northern hemisphere beam, would have derived from the most northerly source, that is from +2° magnetic latitude (see Fig. 2). This effect, where Voyagers appeared to pass right through the beams, has been observed on both Voyager 1 and 2 when outbound at 04.00 and 03.00 LT respectively[6] despite their being at lower jovicentric latitudes (~5°) than when inbound, indicating that at these local times the beams make smaller angles to the magnetic equatorial plane and have a smaller width, possibly due to a smaller source dimension. These sources of bKOM observed by Voyagers when outbound are under study and will be reported separately.

The theory predicts emission of bKOM at the plasma frequency f_p at angles $\beta = \arctan(f_p/f_c)^{1/2}$ with respect to the magnetic field line. Thus assuming a source position at radial distance R_S and magnetic latitude λ_{ms}, the magnetic field magnitude and direction at that point can be computed[11]. Furthermore, assuming a value for f_p within the range of bKOM frequencies observed by Voyager, the theoretical direction of the beam at this frequency can also be computed. If the beam does not pass through the position at which the spacecraft lies when that particular frequency is observed, then the assumed source location is incorrect and another value of R_S is tried until one iterates onto a location that fits. If this technique is applied for all the bKOM frequencies using the corresponding positions of Voyager when they are observed, a radial profile of f_p and therefore of N_e in the Io torus can be constructed. This technique has been applied to terrestrial[12–15] and saturnian[16] myriametric radiations where it could be assumed that the magnetic fields are dipolar, and the source positions could be determined analytically. Jupiter's magnetic field near the equatorial plane at the Io torus and beyond is complicated by the presence of the equatorial current sheet[11] and hence the need for numerical iteration to locate the sources. Voyager 2 inbound data are used because the spacecraft's highest latitude resulted in excursions in and out of the beam during a relatively large number of consecutive jovian rotations. Results from Voyager 1 inbound and Voyagers 1 and 2 outbound will form the basis of a study whose results will be reported separately.

It is assumed, as stated above, that the southern edge of the northern bKOM beam derives from a source at $\lambda_{ms} = -2°$. The positions of Voyager 2 are determined when the leading edge of bKOM at different frequencies is observed. The longitude of Voyager 2 at this time is <202° CML. This is measured for the nine consecutive jovian rotations when the spacecraft was inbound from 95 R_J to 55 R_J. The Io torus plasma density profiles obtained by the remote-sensing technique described above are shown in Fig. 3. Also shown, for comparison, are the profiles determined *in situ* by two experiments[7,17] on Voyager 1 which

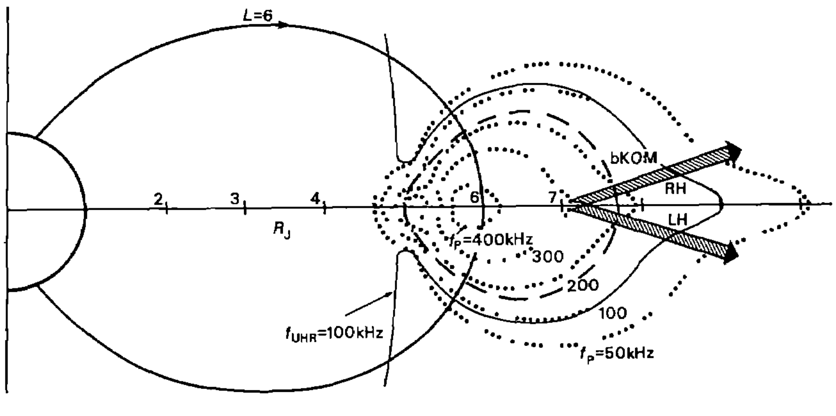

Fig. 2 Schematic of bKOM beaming from the Io plasma torus. Dotted lines represent isoionic contours labelled by plasma frequency f_p. Dotted-dashed line is approximate $f_p = 200$ kHz contour determined *in situ*[1] by Voyager 1. Solid line depicts where upper hybrid resonance frequency $f_{UHR} = 100$ kHz.

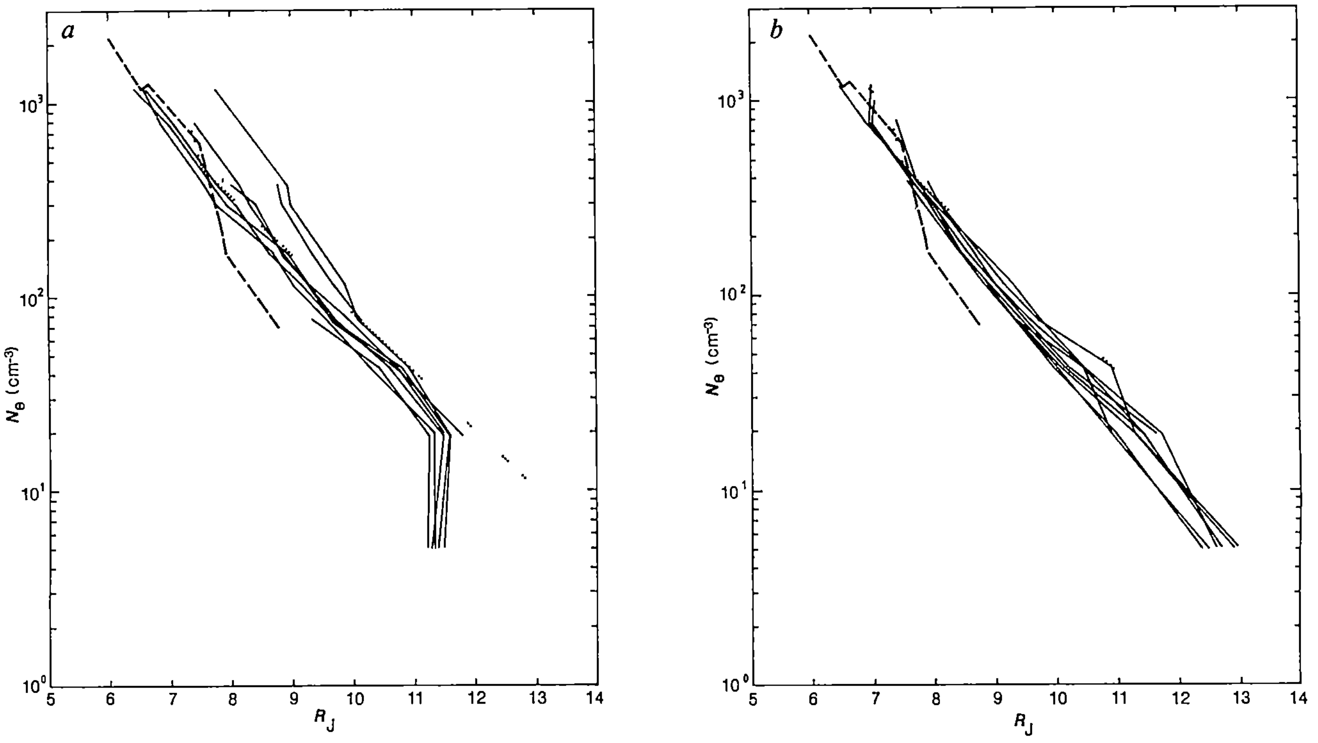

Fig. 3 *a*, Plasma density profiles of the Io torus obtained by remote sensing using the start times of bKOM observed during nine jovian rotations when Voyager 2 was inbound from 95 R_J to 55 R_J. All sources are assumed to be at magnetic latitude $\lambda_{ms} = -2°$. The dashed line represents the profile determined from *in situ* Voyager 1 measurements by the plasma science PLS experiment[17] and the dotted line is derived from measurements of the upper hybrid frequency by the planetary radio astronomy PRA and plasma wave science PWS experiments[7]. *b*, As for *a*, but using the end times of bKOM and assuming all sources are at magnetic latitude $\lambda_{ms} = -1°$.

had traversed the torus 4 months previously. The remotely-sensed profiles are remarkably consistent within themselves considering that there were temporal variations in the torus over the 5 days involved, during which Io made nearly three rotations around Jupiter. The anomalous results at the lowest frequency are possibly due to a wave refraction effect between the source and spacecraft and this is under investigation. The agreement with the Voyager 1 *in situ* profiles is also remarkable considering the time and CML differences between the two sets of measurements. The same remote-sensing exercise has been performed using the trailing edge of the bKOM emissions, again observed in the northern hemisphere but with Voyager 2 moving down in latitude towards the equatorial plane. Figure 4 shows the profiles obtained for a source latitude of $\lambda_{ms} = -1°$ which was found to give better agreement with the *in situ* profiles than $\lambda_{ms} = -2°$. This difference may be due to small differences in the widths or positions of the source regions with CML since these results correspond to longitudes >202° CML, no *in situ* results exist for the variation with CML of the latitudinal width of the source ESUH waves, although certain asymmetries with respect to the equatorial plane have been observed[18]. The difference may also arise from the fact that the centrifugal equator, which is the symmetry plane for the Io torus plasma, has a magnetic latitude which differs by ~1° between the two cases due to their CML differences[19].

Note that the slopes of the remotely-sensed profiles differ only slightly from that of the *in situ* profile determined from the observations of upper hybrid waves (dotted line). If one had assumed that the source latitude decreased by $\simeq 0.5°$ with increasing distance from 8 R_J to 13 R_J the slopes would be identical. Such a decrease in the width of the ESUH emission regions with distance has been observed[18].

Because the beam widths depend to a first approximation on the latitudinal dimensions of the source, further computations show that for Voyager 2 to have observed the top edge of the northern beam when inbound on the dayside, the source ESUH waves would have had to be restricted to within $\sim\lambda_{ms} \simeq 0.5°$ of the equatorial plane and even then the effect would only have been visible at the higher frequencies. Alternatively, had Voyager 2's excursion into the northern hemisphere been $>\lambda_m \simeq 20$-$25°$ it would have observed the whole beam at all frequencies.

In conclusion, bearing in mind the temporal and longitudinal variations of the torus plasma density and of the current sheet magnetic field which has been assumed constant in the model used, it is difficult to imagine that the remotely-sensed profiles obtained using data from a spacecraft $>3\times10^6$ km from the source could be so consistently similar to the *in situ* profiles unless the linear theory proposed is valid.

I thank Yolande Leblanc, Observatoire de Paris, for providing the PRA data and for much advice and information, Jack Connerney, NASA Goddard Space Flight Center, for supplying the magnetic field program and Fran Bagenal, Imperial College, London, for helpful discussions.

An icy-glue model of cometary nuclei

Tamas I. Gombosi* & Harry L. F. Houpis*

Central Research Institute for Physics, Hungarian Academy of Sciences, H-1525 Budapest 114, POB 49, Hungary

Since 1950 a number of models have been proposed to explain the observations of comets. For the most part, the icy conglomerate model of Whipple[1] has been the standard which others have followed. In light of the recent images made of comet Halley, by the Vega and Giotto spacecraft, we suggest here that the nucleus is composed of rather large (tens of centimetres to hundreds of metres) porous refractory boulders, 'cemented' together with an ice–dust grain mix of the icy conglomerate type. This model retains the advantages of the icy conglomerate formalism on a local level, and also introduces a new global framework. We discuss the model in terms of the improving knowledge about comets, the creation of the nucleus in the cosmogonic sense, and expectations of the future analysis of data and observations.

As well as explaining the production rate of various chemical species in the cometary coma, previous nucleus modelling has been constrained by the following observational facts: the light-curve of a comet is asymmetric with respect to perihelion; most short- and intermediate-period comets ($P < 200$ yr) 'turn on' inside ~ 3 AU; some new comets show gas activity at very large heliocentric distances (5–10 AU); and comets have been known to split. In the past few years, a number of important observations have been made which further constrain a nucleus model. Radar observations of comet IRAS–Araki–Alcock[2] have shown that the nucleus is highly non-spherical, that the surface is rough on a scale larger than the radar wavelength (3.54 and 12.9 cm), and that there is an expanding 'skirt' of non-gravitationally bound material with individual radii larger than a few centimetres. The clumpy nature of OH emissions in the atmosphere of comet Halley[3] is suggestive of extended sublimation sources.

These most recent observations, together with an assortment of other evidence, led Weissmann[4] to postulate a primordial rubble pile of small icy conglomerates. Although this model, and similarly that of Donn *et al.*[5], can also explain the splitting of comets as the 'breaking free of weakly bonded fragments', the recent images of the comet Halley nucleus by the Vega and Giotto spacecraft[6–8] suggest another way of looking at this process as well as the nucleus as a whole. The shape of the Halley nucleus is quite non-spherical ($\sim 7.5 \times 7.5 \times 15\ \text{km}^3$) with altitude variations of ~ 100 m. About seven major jets, some of them grouped into bundles (the source diameter of each bundle being ~ 3 km, whereas that of the single dust jets appears to be ~ 500 m) indicate an origin on the sunlit side of the nucleus and point in the general direction of the Sun. The source area of all the active jets is estimated to be $\sim 10\%$ of the total surface area. The rest of the surface appears to be inactive, although a low, undetected dust activity cannot be dismissed. Furthermore, the surface has a rather uniform albedo of a few per cent, indicative of a porous dust coating with little or no ice; this is also consistent with the infrared measurements of an average surface temperature over 300 K.

These latest results from the spacecraft encounters with comet Halley lead us to propose a new model of the nucleus. We suggest that the nucleus is composed of rather large (tens of centimetres to hundreds of metres) porous refractory boulders (similar in composition to the outer asteroid belt objects and the irregular outer satellites of the giant planets; that is, hydrous silicates containing complex carbon compounds) 'cemented' together with an ice–dust grain mix of the icy conglomerate type ('Whipple glue'). As the nucleus evolves with repeated passages close to the Sun, those regions above the largest boulders, which may be only a few metres thick, become depleted in their volatile ices and hence inactive. We call these regions dust plates, and they may be only a few centimetres thick. On the other hand, the regions between the largest boulders, where there are the smaller boulders and the ice–dust mix, may penetrate quite deep into the nucleus (50–100 m) and hence are not likely to become inactive for several (perhaps 50–100) orbits around the Sun. We call these regions macropores to distinguish them from the micropores in the Whipple glue. It is from here that the jets originate. Figure 1 shows conceptual drawing of such a nucleus.

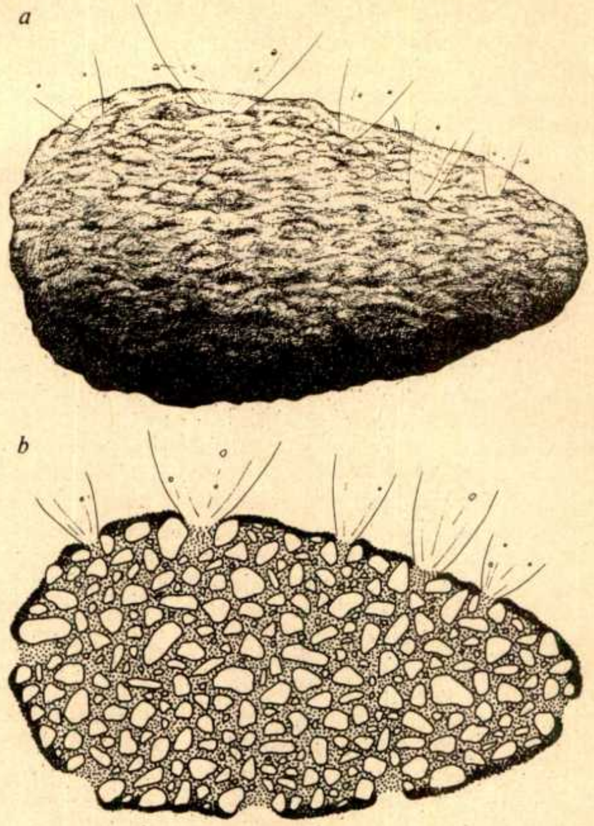

Fig. 1 *a*, Three-dimensional perspective of a comet-Halley-shaped icy-glue cometary nucleus showing active and inactive macropores, release of small boulders, surface altitude variations of porous refractory framework imbedded in Whipple glue, outer dust covering, and penetrations of the form surface by potentially active macropores.

This model explains in a natural way the above observations. The general shape of the nucleus and its surface altitude variations are a direct consequence of the low self-gravity and the large boulder framework, whereas the uniform porous dust covering is a result of the volatile ices receding below the surface and the creation of dust plates.

Jets, as the major sources of cometary activity, are the result of a group of macropores coming into view of the Sun. Depending on the placement of the boulders, the jets may appear as line sources delineating the shape of the large boulders near the surface or as point sources for a more evolved surface topology. These appearances are reminiscent of the surface regions sketched by Sekanina and Larson[9,10]. Furthermore, the latest analysis of the Vega images indicates the existence of both linear and point sources on comet Halley (B. A. Smith, personal communication).

The percentage of comet Halley's surface capable of significant dust emission can be estimated from the observed jet activity. Using a total active area of $\sim 50\ \text{km}^2$ as seen by Keller *et al.*[6] for the Halley nucleus, one can conclude that as much as 44% of the entire surface is capable of jet activity.

Typically, we expect the width of the smallest dimension of a jet at the surface to be no more than a few hundred metres. However, a few hundred metres from the surface the jet will have expanded laterally due to the existence of a gas-pressure gradient between the site above the macropore and that of the surrounding dust plates[11].

---

* Present address: Space Physics Research Laboratory, Space Research Building, University of Michigan, Ann Arbor, Michigan 48109, USA (T.I.G.); Centre of Astrophysics and Space Science, University of California, San Diego, California 92093, USA (H.L.F.H.).

The literature often suggests that jets may originate from fissures due to thermal stress, which have opened on the surface. The freshly exposed ice then provides the source for the jets. Our contention is that although the surface may crack, the resulting excess production will be of an outburst nature rather than a steady jet. The reason is that exposed ice will quickly recede to form a dust mantle (only a few tenths of a centimetre are needed) and return the excessively active surface to that of a diffusion process. Thus, although fissures and unglued small boulders may account for outbursts, the macropores are responsible for the steady jet activity.

Splitting of comets is now explained by pieces of the framework becoming unglued; that is, the Whipple glue around a particular boulder has been sublimed and entrained to such a point, that the boulder eventually breaks free. This process which is obviously random with respect to the comet's orbital parameters and heliocentric distance, explains why more splitting fragments are a small fraction of the original nucleus, separating with a small relative velocity and disappearing visually in ~100 days, and allows for 'flaring' activity as the new uncovered Whipple glue is exposed to the solar environment. The decrease in splitting frequency as a comet spends more time in the inner Solar System may be due to such processes as densification of the ice-dust grain mix[12], and the recondensation near the surface of volatile ices which have sublimed from the comet interior[13]. We also suggest that outbursts from comets may be in part the result of the much smaller boulders becoming unglued. We note that a major difference between our mechanism and that of the rubble-pile model is that splitting of the icy glue nucleus is a natural consequence of the structural make-up, whereas the rubble-pile theory must invoke 'weakly bonded fragments' and the necessity for a heat wave to have some *ad hoc* preference to propagate along the interfaces between them.

The activity of some 'new' comets at large heliocentric distance may also be partially explained by postulating that these comets are indeed new to the inner Solar System, with the entire surface capable of dust and ice production, and that comets are probably significantly larger than previously thought. Thus, it is not until the inactive dust plates begin to predominate after a few orbits that activity at large heliocentric distances begins to subside. This idea may of course be used in conjunction with the chemical differentiation model[14] to account for the 'tapering off' of activity at smaller heliocentric distances. The asymmetric behaviour of cometary light curves about perihelion can be explained in part by the location of the active macropores.

For the creation of an icy-glue nucleus we suggest the following model. The large porous boulders first agglomerated in the pre-Jupiter region. The growing Jupiter and Saturn protoplanets caused the diffusion of a substantial amount of this material through the pre-Uranus-Neptune zone. Because agglomeration of the original influx of material into this outer zone was quite slow, as suggested by a number of theories[15], the boulders arrived to find the ice and dust still in the small-grain phase and somewhat extended about the ecliptic plane. The boulders and grains then came together to form the icy-glue nuclei described previously, with the Uranus and Neptune protoplanets ejecting them to the Oort cloud.

Although this model is only illustrative and needs to be subjected to a proper dynamical analysis, we point out an important difference between the icy-glue complex and the icy conglomerate models. On the one hand, the icy conglomerate model has its basic building blocks constructed from both dust and ice grains, although the mixture may be heterogeneous relative to the centre of the nucleus or the individual building blocks. On the other hand the icy-glue model is built from two different types of basic units: porous refractory boulders with little or no initial volatile content, and grains of dust and ice. This fundamental difference may prove useful in constructing a cosmogonic theory of the Solar System.

We thank Drs Bradford Smith, Akos Körösmezey, Steven M. Larson and Károly Szegõ for useful discussions, Carole Turner for the careful editing of this manuscript and Diane McGregor for the artwork of Fig. 1. Part of this work was supported by NSF grant AST-8605994.

Distribution of energetic particles near interplanetary shocks

A. Hewish* & S. Bravo†

* Mullard Radio Astronomy Observatory, Cavendish Laboratory,
Madingley Road, Cambridge CB3 0HE, UK
† Instituto de Geofisica, Ciudad Universitaria, Codigo 04510,
Mexico D.F.

The acceleration of charged particles by collisionless shocks is a process of considerable importance in astrophysics, but the physical mechanism is not yet understood in detail. Energetic particles near interplanetary shocks may be studied *in situ* by spacecraft, but little is known about their distribution across the shock surface because of inadequate knowledge of the location of the sampling point in relation to the whole disturbance. A ground-based method has been developed[2] which enables shock-associated disturbances to be mapped in three dimensions, and we have used it, in combination with near-Earth spacecraft measurements, to study how the particle flux varies for shocks travelling at different angles to the Sun-Earth line. We have observed a pronounced east-west asymmetry which indicates that the inclination of the interplanetary magnetic field to the shock surface must be a potent factor in the acceleration process.

The method of mapping the disturbances was based on daily observations of a large grid of radio sources, the scintillation of which was related to the mean plasma density along many different lines of sight[1]. Examples of the structures of large-scale disturbances revealed by this method have been described previously[2-4]. It was found that strong shocks typically occurred at the front of enhanced density shells which subtended a solid angle of $\sim\pi/2$ sr at the Sun. The shells were compression zones, caused by sudden eruptions of fast solar wind which lasted for several days, and they could always be traced back to sources coincident with coronal holes[5]. Among the 96 disturbances detected during August 1978-September 1979, 73 were classified as 'erupting streams'; the remainder were co-rotating interaction regions of longer duration[6]. All significant shocks (shock strength $\geqslant 1.5$) recorded by near-Earth spacecraft were accompanied by compression zones that were mapped by our method.

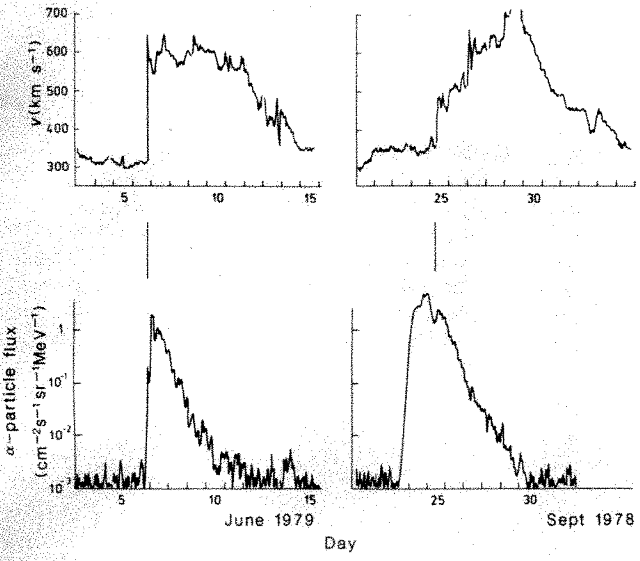

Fig. 1 Temporal variations of solar wind speed (v) and α-particle flux in the range 9–70 MeV associated with two strong interplanetary shocks. Vertical line, time of shock passage at the Earth.

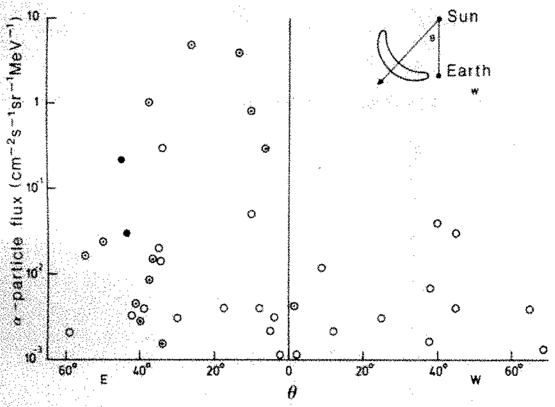

Fig. 2 Peak α-particle flux observed for shocks travelling at different angles, θ, to the Sun–Earth line. Shock strengths: ●, ⩾3; ⊙, ⩾2; ○, <2.

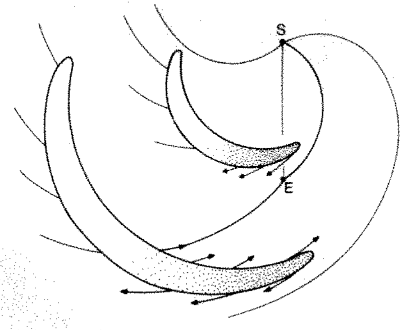

Fig. 3 Schematic diagram showing the regions of greatest particle acceleration when the shock disturbance has reached distances from the Sun (S) 1 and 2 AU. The spiral magnetic field lines correspond to a solar wind speed of 350 km s^{-1}. Arrows denote the directions of particles moving away from the shock. The field line through the Earth (E) beyond 1 AU is calculated for a speed of 600 km s^{-1}, appropriate to the high-speed flow behind the shock.

However, we sometimes detected eruptions unaccompanied by shocks, either because the shocks were too weak or because they did not strike the Earth.

All the disturbances that were classed as erupting streams, and that also caused sudden geomagnetic storms, are listed in Table 1 together with spacecraft measurements of the shock strength. Also given are the estimated directions of travel (θ), relative to the Sun–Earth line, obtained by our method. As described previously, the angles were obtained by comparison with theoretical maps computed for simple models[6]. The accuracy of ($\sim\pm20°$) is not high, but there was usually no difficulty in placing disturbances to the east or west of the Sun–Earth line.

For the energetic particle data we used the α-particle flux in the range 9–70 MeV from the GMS/SEM satellites[7]. During the largest particle events the flux increased by a factor of $\sim10^3$ (Fig. 1). Table 1 gives the peak flux associated with each shock, smoothed over a few hours. When the particle fluxes are plotted against the directions of travel (Fig. 2), a pronounced asymmetry is evident. Only shock disturbances centred on directions to the east of the Sun–Earth line produced the largest enhancements of flux. The background flux was typically $\sim2\times10^{-3}$ cm^{-2} s^{-1} sr^{-1} MeV^{-1}, and enhancements greater than four times this value occurred on average only once or twice per month. At this level there were 16 events associated with shocks passing on the east, compared with 3 in the west. Above 5×10^{-2} cm^{-2} s^{-1} sr^{-1} MeV^{-1}, there were 8 shocks in the east and none in the west.

The shock strengths (downstream/upstream density) were taken from refs 13, 14. The α-particle flux is in units of cm^{-2} s^{-1} sr^{-1} MeV^{-1}.

Assuming that all the shocks are similar, it follows that the particle flux at the shock surface follows the distribution shown in Fig. 2, but in the opposite sense. Thus, a shock travelling directly towards the Earth would generate a flux which peaked at 20-30° west of the Sun-Earth line.

The asymmetry can be understood if the acceleration depends on the angle between the magnetic field and the shock surface. Figure 3 shows the geometry for an idealized interplanetary field, assuming an ambient solar wind of 350 km s^{-1}. For co-rotating shocks beyond 1 AU caused by a stable high-speed stream, the maximum particle flux occurs when the shock surface is nearly parallel to the field[8] (the 'quasi-perpendicular' case). For a spherical shock front appropriate to an erupting stream, it is clear from Fig. 3 that this condition can occur on one side of the disturbance only, and the asymmetry is in the correct sense to explain our observations. Another factor favouring the parallel field condition is the co-rotation of the stream following its sudden eruption. This will tend to increase the curvature of the shock front on the same side of the disturbance.

In addition to the asymmetry, the characteristic sharp rise and slow decay of the flux (see Fig. 1) is readily explained. Recent evidence[9,10] supports a model in which particles are accelerated continuously near the shock and then diffuse away in both directions along the field lines. From the geometry in Fig. 3 it may be seen that for a shock passing to the east, the field line through the Earth makes connection only shortly before the shock arrives, but thereafter remains connected for several days as the disturbance propagates beyond 1 AU. The systematic eastward movement of the point of contact as the shock recedes from the Earth effectively scans the particle distribution in a different way.

In previous studies of energetic particle events, associations with solar flares have been assumed and conflicting results have been obtained. It has been deduced, for example, that flares are most effective when they occur on the west of the disk, which supports the theory that energetic particles are released at the flare site and channeled along 'well-connected' field lines to the Earth[11]. By contrast, more recent work has suggested that the flux is greatest for shocks associated with flares on the east of the disk[12]. These discrepancies are not surprising in the light of our observations that shocks are caused by eruptions generated by coronal holes and not by flares[6]. Our present conclusions are qualitatively similar to those of ref. 12, but differ in showing a larger and more sharply defined east-west asymmetry for the particle flux.

Searching potential energy surfaces by simulated annealing

L. T. Wille

SERC Daresbury Laboratory, Daresbury, Warrington WA4 4AD, UK

Many problems in physics[1], chemistry, biology[2] and mathematics[3] involve the determination of the absolute minimum of a certain multidimensional function. In most cases of practical interest this is a complicated matter, owing to the presence of local minima, and even more so because the number of local minima often increases exponentially with the problem size. Standard techniques apply local optimizers to many random initial configurations, but soon become intractable as the dimensionality increases. Here I show how the simulated annealing method can be used to guide a search towards the absolute minimum. The method is illustrated on a problem recently discussed in this journal, namely the minimum-energy configuration of equal charges confined to a sphere. This problem, although easy to visualize, can be used to simulate much of the complexity of the above problems by considering a large number of particles. In this limit several minima have been found that have previously been missed by other authors using classical techniques.

To determine the ground-state configuration of a system of interacting particles one needs to find the absolute minimum on the potential-energy surface (strictly speaking it is the free energy that has to be minimized, but one usually assumes the system to be at zero temperature). A local minimum can be found by one of many possible search techniques[4], most of which are based on a gradient method. Starting from a certain point on the potential energy surface one takes a step in a direction determined by the line of steepest descent and repeats this process until a minimum is reached, to within a certain accuracy. The collection of all points from which the same (local) minimum is obtained by this algorithm is called the catchment region of the minimum. This whole procedure is repeated a number of times starting from random initial configurations and produces a list of local minima, the smallest of which is taken to be the global minimum. Obviously there is no guarantee that the global minimum will be found in this way, especially if the catchment region is narrow. Alternatively, instead of taking random initial configurations one tries to deduce growth schemes from low-dimensional systems. The algorithm is then applied to configurations obtained from a set of growth rules. This procedure often produces highly symmetric configurations; the previous remarks are then even more pertinent.

Obviously a method that avoids getting trapped in local minima would increase the likelihood of detecting the global minimum. It has been shown[5,6] that a continuous version of the simulated annealing method proposed by Kirkpatrick *et al.*[7] for discrete problems can be used for this purpose. An overview of simulated annealing and its applications has been presented elsewhere[8] and only a brief description will be given here. Consider the potential energy to be minimized as $E(\mathbf{r}_1, \ldots, \mathbf{r}_N)$, where the $\mathbf{r}_i$, $i = 1, \ldots, N$ are the positions of the particles. The simulated annealing method uses the Metropolis prescription[9] to decide whether or not to accept a random step $\Delta\mathbf{r}_i$, $i = 1, \ldots, N$. If the associated energy change $\Delta E = E(\mathbf{r}_1, \ldots \mathbf{r}_i + \Delta\mathbf{r}_i, \ldots, \mathbf{r}_N) - E(\mathbf{r}_1, \ldots, \mathbf{r}_i, \ldots, \mathbf{r}_N)$ is negative, the step is accepted, otherwise it is accepted with a probability $P = \exp(-\Delta E/T)$, where T is the temperature (in reduced units). Obviously this corresponds to a random walk on the potential energy surface, where the walker feels attracted to minima. In the process of annealing the system is started in a random initial configuration at a sufficiently high temperature. Several series of steps are attempted and the temperature is then reduced by a certain factor (typically 0.75-0.9). This process is repeated until no further improvements have been made over a number of iterations. This scheme is similar to the way a crystal is grown from the melt. If the fluid is cooled too quickly (or quenched) a

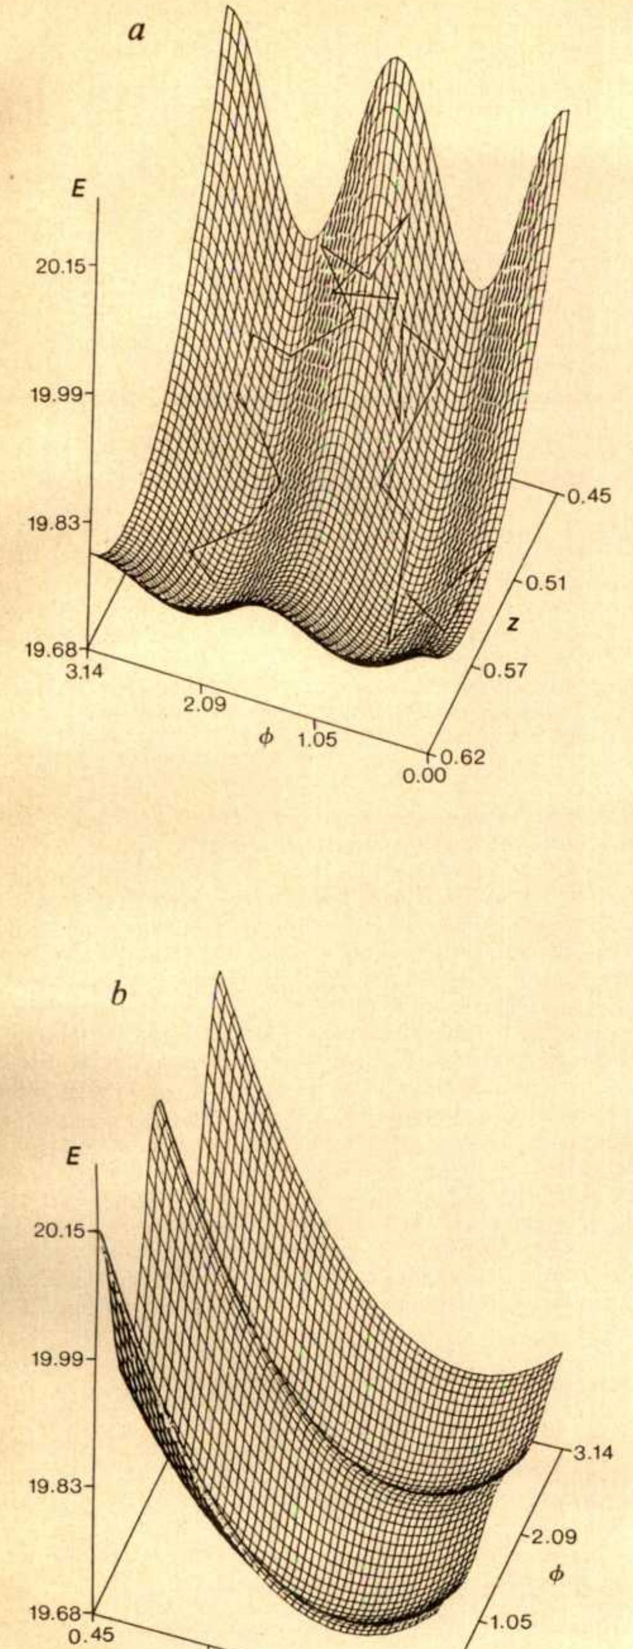

Fig. 1 The potential energy surface for an antiprismal arrangement of charges: z is the distance of the planes from the equator and ϕ is the relative rotation angle. *a*, The random walk towards the minimum. *b*, A cubical arrangement $\phi = \frac{1}{2}\pi$, $z = 0.577$ corresponding to a saddle point on the potential energy surface.

disordered structure with many defects results. This would correspond to a local minimum. On the other hand, the true crystalline ground state can be obtained by a process of slow annealing. It was this powerful analogy which motivated Kirkpatrick *et al.* to develop the simulated annealing method[7].

In the calculations presented here the initial temperature was taken from a short preliminary simulation and the step length was adjusted so that 25–50% of the steps were accepted. Typically 100 moves for each particle were attempted before the temperature was reduced by a factor of 0.9. However, it was found that in many cases a much faster cooling produced the same results. As soon as the energy dropped below a certain value (also taken from a preliminary simulation) a steepest-descent optimizer was called. Finally the whole process was repeated ten times for each number of particles. This precaution was taken because it was found previously[6] that, in spite of slow cooling, trapping in a low-lying local minimum can still occur. The use of a local optimizer in the later stages of the simulation is also an innovation and gives rise to a great reduction in computation time.

Recently there has been renewed interest in the minimum-energy configurations of systems of charged particles confined to a circle or a sphere[10–17]. The problem of the distribution of equal point charges on a sphere is long standing; it was investigated at the beginning of this century by J. J. Thomson and D. Hilbert and later by many mathematicians (for a historical review see ref. 18). Very little analytical progress has been made and most of the later work[19–21] uses numerical methods to find the global minimum for this and other extremal problems over a spherical surface. It has been shown[22] that if the configuration possesses rotational symmetry about the diameter through every particle, this configuration is in equilibrium whatever the force law is, provided that it depends only on the distance between the particles. In this work the charges are assumed to interact via a Coulomb potential $V = 1/r$. It is then known that there are no minimum-energy configurations with charges inside the sphere because the potential is harmonic, that is, it satisfies the Laplace equation[23,24]. Hence the particles can be restricted to move on the surface of the sphere during the simulation, a simplification that would no longer be possible for a potential of the form $1/r^n (n > 1)$.

Table 1 shows the minimum-energy configurations for N unit charges ($5 \leq N \leq 20$) confined to a sphere with unit radius, determined by the simulated annealing method. These configurations have been rotated so that the major symmetry axis lies along the north–south direction. The charges are grouped in planes parallel to the equator. In the planes the charges form polygons which are rotated relative to one another. A notation such as $15^3 1$ (height 0.610) means that there is one charge at the north pole, 5 charges at a height 0.610 (in units of the sphere radius), 5 in the equator plane, 5 at a height −0.610 and one at the south pole. The surprising fact that the charges tend to form parallel polygons has been noticed by previous authors. However, this is not a universal feature as is illustrated by the low-symmetry solution for $N = 11$, missed in ref. 17, but found by other authors[19,21]. Other improvements over the results in ref. 17 for $N = 13$ and 15 have also been given before[21]. However, the present results disagree with published results for $N = 14$, which according to ref. 21 should form a $14^3 1$ configuration (with an energy of 69.496), but which is found here and in ref. 17 to form a $16^2 1$ configuration. Finally, in the range $N \leq$ 17–20 which was investigated for the first time in ref. 17, improvements have been found for $N = 19$ and $N = 20$.

Figure 1 illustrates visually how simulated annealing works, by showing the results of an actual simulation for $N = 8$. It is known that when $N = 8$ the charges do not occupy the corners of a cube, and in general the Platonic solids do not necessarily produce the minimum-energy configuration. Although Leech's analysis[12] shows that charges placed on the corners of a regular polyhedron are in equilibrium, this is not in general a stable

Table 1 Minimum energy configuration for N charges confined to a sphere, interacting via a Coulomb potential

Results obtained by the simulated annealing method that are believed to correspond to the global minima on the potential energy surface.

equilibrium. A cubical arrangement, for example, corresponds to a saddle-point on the potential energy surface. Consequently it is possible to deform the cube continuously to the true ground state[20], a case of spontaneous symmetry breaking. To show how the method works, I use the following simulation. Consider the restricted problem where two squares of charges lie in parallel planes a distance z above and below the equator and with relative rotation angle ϕ. The cube corresponds to $z = 1/\sqrt{3}$ $(= 0.577)$ and $\phi = 0$, and the true ground state is $z = 0.560$, $\phi = \pi/4$. Figure 1 shows the potential energy surface $E(z, \phi)$ for this constrained geometry, and the random walk towards the minimum (Fig. 1*a*). The potential energy $E(z, \phi)$ is a periodic function of ϕ, with period $\pi/2$; hence there are four equivalent minima, two of which are shown in Fig. 1. The simulation started in the right-hand side in Fig. 1*a*, at $T = 0.1$, attempted one move $(\Delta z, \Delta\phi)$ (Δz and $\Delta\phi$ are distributed uniformly in $[-0.1, 0.1]$ and $[-0.5, 0.5]$ respectively) after which the temperature was reduced by a factor of 0.9. Initially (at 'high' temperatures) almost all steps are accepted, then there is an intermediate regime where the walker is wandering on a 'ridge', and finally it walks down the 'valley' towards the minimum. Note that in a Monte Carlo simulated annealing the walker tunnels through barriers, rather than surmounting them as in a molecular dynamics simulation.

Simulated annealing is a powerful way of finding low-lying minima on a potential-energy surface, in particular for cases where steepest descent methods become too time-consuming. This has been illustrated by presenting several improvements over previous work for the three-dimensional charge-confinement problem, which is of mathematical interest[18] and may be relevant to several fields of physics[17]. Moreover, the method is very general and can easily be applied to similar problems. Results for clusters of atoms interacting under two-body Lennard-Jones forces[1] will be presented elsewhere. Even in cases where the interactions between particles cannot be expressed as a two-body force, as in quantum chemistry or solid state physics, a generalization of the method, following Car and Parrinello[25], may be possible.

Large AlCuLi single quasicrystals with triacontahedral solidification morphology

B. Dubost, J-M. Lang, M. Tanaka, P. Sainfort & M. Audier*

Cegedur-Pechiney, Centre de Recherche et Développement, B.P.27, 38340 Voreppe, France

* Permanent address: Laboratoire de Thermodynamique et Physico-Chimie Métallurgiques, UA CNRS 29, Domaine-Universitaire, B.P. 75, 38402 Saint Martin d'Hèref, France

The discovery of icosahedral symmetry in rapidly solidified Al-Mn alloys[1] has stimulated considerable research activity mainly because it appeared to violate the classical rules of crystallography. Hence, it left the field open for numerous reports on rapidly-solidified phases with icosahedral symmetry in aluminium based alloys. However, a challenging goal for materials scientists has always been the fabrication of large quasicrystals that would allow further investigation of the crystallographic and physical properties of this new form of material. This paper reports the first evidence of triacontahedral solidification morphology of large quasicrystalline dendrites within an as-cast Al-Cu-Li alloy with composition close to that of the Al_6CuLi_3 phase.

The first evidence of stable intermetallic phases with icosahedral symmetry, in the aluminium-lithium-copper-magnesium system[2], can be considered as an important step towards the fabrication of large quasicrystals. The intermetallic Al_6CuLi_3 compound, designated T2 (ref. 3) has been successfully cast into large dendrites surrounded by a residual eutectic, and nucleated and grown as a fine precipitate in an aluminium-rich matrix[4].

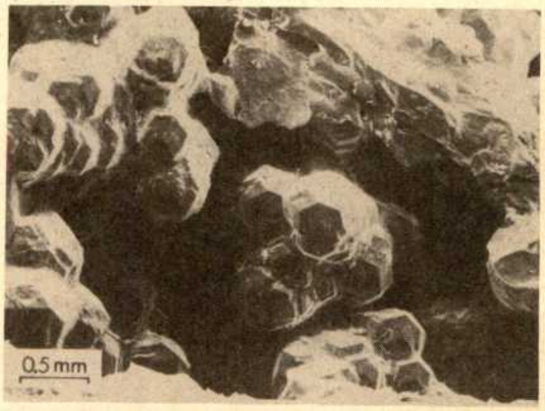

Fig. 1 Scanning electron micrograph in secondary electron mode showing the macroscopic morphology of the T2-Al_6CuLi_3 single quasicrystalline dendrites. Each dendrite consists of stacked triacontahedra with the same orientation.

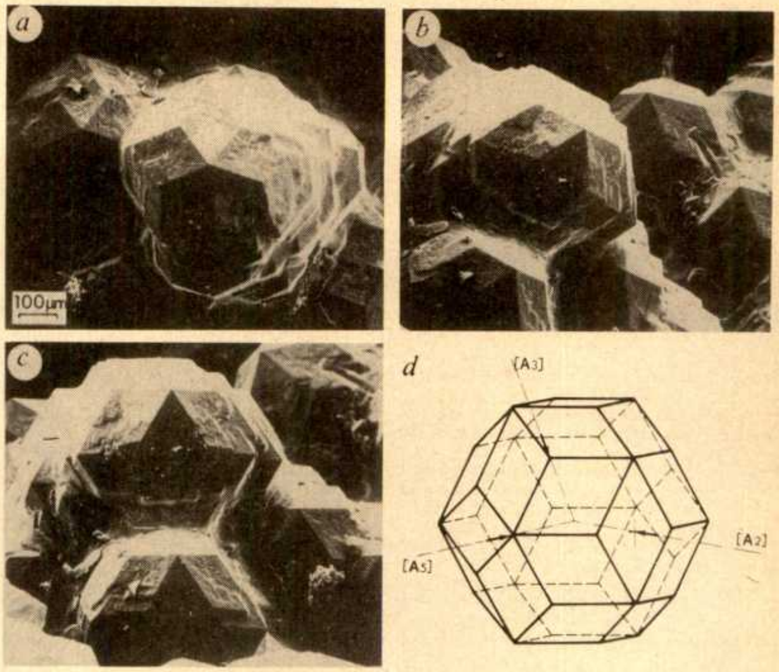

Fig. 2 Triacontahedral solidification morphology of a T2-Al_6CuLi_3 single quasicrystal viewed along a 5-fold axis (*a*), a 3-fold axis (*b*) and a 2-fold axis (*c*). These types of symmetry axes are noted on the drawing of a triacontahedron in (*d*).

These T2 phases revealed an icosahedral structure in orientation relationships with the face centred cubic matrix[4].

However, the direct production of single-phase intermetallic alloys with T2 composition proved difficult because of the occurrence of the cubic R-Al_5CuLi_3 intermetallic compound having a composition very close to that of T2-Al_6CuLi_3 (ref. 3). An inadequate alloy composition would then lead to a duplex matrix structure consisting of an R phase polyhedral core surrounded by a continuous layer of T2 (due to the non-congruent melting character of the latter phase) with orientation relationships between these 'cousin' phases[5]. We have made a major advance in this field, and detail the spectacular morphological features associated with it.

After careful weighing of very high purity aluminium, lithium and copper base metals, an alloy with chemical composition $Al_{6.4}Cu_{0.9}Li_{2.7}$ was cast at 690 °C under a controlled atmosphere in a graphite mould. The alloy was cooled slowly from 620 to 570 °C with a solidification time of 1 h, as recorded by thermal analysis. Following casting and slow cooling to room temperature, the ingot was broken open. It exhibited well defined primary dendrites along free internal surfaces, these dendrites consisting entirely of large T_2 quasicrystals to the exclusion of the other equilibrium phases.

The macroscopic solidification morphology of the T2 dendrites is of major interest: they clearly consist of stacked triacontahedra (the triacontahedron is a non-regular polyhedron with 30 rhombus-shaped faces, 32 vertices, 60 edges and icosahedral symmetry). These T2 dendrites, ~0.5 mm in diameter, can be seen in the low magnification scanning electron microscope images (Fig. 1). Their 2-, 3- and 5-fold symmetry axes, oriented perpendicularly to the picture plane, are shown in scanning electron micrographs in Fig. 2*a*, *b* and *c* respectively. They exhibit nearly perfect triacontahedral morphology (Fig. 2*d*), with the exception of a number of growth steps along some rhombic faces.

Such a triacontahedral morphology is a novel observation in crystallography and mineralogy. The triacontahedron is known to be the basic volume of the three-dimensional Penrose tiling[6,7]. This morphology can undoubtedly be attributed to the quasicrystalline nature of the primary dendrites. X-ray powder diffraction and selected area electron diffraction patterns obtained from crushed macroscopic triacontahedra (Fig. 3) reveal that the primary dendrites consist solely of T2-Al_6CuLi_3 (with no occurrence of R-Al_5CuLi_3 or other phases such as aluminium).

The striking similarity between the morphological features of these packed triacontahedra (macroscopic scale) and the atomic structure model for quasicrystals (ref. 8) recently proposed is also of great interest. This atomic structure model involves triacontahedral atomic decoration of the two rhombohedral tiles of the 3-dimensional Penrose tiling[6,7] (Fig. 4). On the other hand, the cubic Im3 structure of the R phase close to T2 (refs 9, 10) consists of a regular packing of triacontahedra[5].

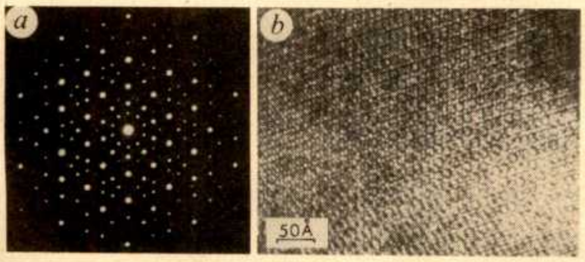

Fig. 3 *a*, Electron diffraction pattern and *b*, corresponding high resolution transmission electron microscopic image obtained along the five-fold axis from a fragment of crushed T2-Al_6CuLi_3 macroscopic triacontahedron.

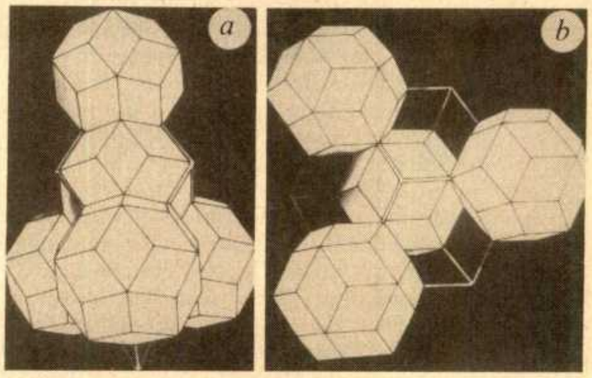

Fig. 4 Triacontahedra decorating the prolate (*a*) and oblate (*b*) rhombohedra of 3-dimensional Penrose tiling[5,8].

Using such samples, further work is now needed to describe more precisely the microscopic and geometrical features of this new morphology and to implement the structural models for quasicrystals. We propose that the results presented here on the icosahedral AlCuLi phase will lead to a better understanding and successful evaluation of the properties of this new type of material.

We thank R. Chamard, C. Bernard, P. Duroux, E. Janot and G. Duverneuil for their technical support and A. Dubus and F. X. Gilles for their contribution to previous steps of this study. Financial support of the Direction des Recherches Etudes et Techniques is gratefully acknowledged.

Evidence for carbonate in the mantle

G. W. Berg

Geology Department, University of Port Elizabeth, PO Box 1600,
Port Elizabeth 6000, South Africa

The presence of primary carbonate in kimberlite magmas, which erupt to the Earth's surface from depths of $\geq$150 km, carrying with them the rare elemental form of carbon, diamond, is evidence for a reservoir of carbon in the Earth's mantle. Hypotheses about the form in which this carbon is stored were largely speculative until laboratory experiments[1,2] established that at depths of $\geq$50 km carbon can be incorporated in the solid carbonates, dolomite ($CaMg(CO_3)_2$) and magnesite ($MgCO_3$). However, only one instance of minute inclusions of dolomite in a sample of rock from the mantle has ever been recorded[3], despite 25 years of intensive study of these rocks. Here I report the presence of hitherto undescribed brucite/calcite intergrowths ($Mg(OH)_2/CaCO_3$) in mantle-derived xenoliths which occur in the diamond-bearing volcanic kimberlite pipes of Kimberley, South Africa. These intergrowths could reflect the presence of relatively abundant dolomite in the mantle. They seem to have been overlooked to date because of their fine textures and susceptibility to replacement by secondary serpentine.

The brucite and calcite are finely intergrown on a 10–20-μm scale (Fig. 1). Together, they form black grains of up to ~4 mm which are sometimes described in hand specimens as 'graphite' or 'carbon'. The intergrowths or their alteration products have been studied in a coarse garnet lherzolite, a porphyroclastic lherzolite and a porphyroclastic wehrlite. In the porphyroclastic samples, deformation has affected the exterior form of the black grains containing brucite and calcite, but not their microtexture (Fig. 1). The wehrlite shows about eight grains of brucite/calcite intergrowth per thin section and also contains metasomatic phlogopite. The other two samples studied contain an average of one grain of intergrowth per thin section. The collection of 70 nodules which yielded the three samples studied here is probably biased against metasomatized specimens. Thus the intergrowths may be more widely distributed in peridotite nodules from the Kimberley area than the present sampling indicates.

The brucite/calcite intergrowths are interpreted as reflecting the decarbonation products of dolomite, by analogy with the general reaction

$$CaMg(CO_3)_2 \rightarrow CaCO_3 + MgO + CO_2$$

used to describe the formation of pencatite and predazzite marbles, the periclase being hydrated to brucite[4]. The reaction in peridotite xenoliths is thought to have proceeded in response to decompression resulting from the rapid emplacement of their kimberlite hosts from depths of >100 km. The exact path of the reaction is not certain. It is known to be complicated by solid-solution effects[5] and the mantle analogue of dolomite in the equation is likely to be a solid solution between dolomite and magnesite[6]. The term dolomite is used here in this broad sense.

According to experimental data recently reviewed in ref. 7, a decrease in pressure to ~20 kbar could result in the reaction of mantle dolomite with coexisting silicates, with the accompanying evolution of CO_2 vapour. Eggler[8] has suggested that these reactions may prevent dolomite from reaching the Earth's surface. However, the observations reported here suggest that the silicate–carbonate reactions are too slow to consume the dolomite, so that the metastable silicate–carbonate assemblages persist to $\leq$5 kbar, when dolomite decarbonates[5] independently of surrounding silicates.

A wide range of oxygen fugacities has been postulated for the upper mantle[9]. The lower ranges (iron–wüstite buffer) are incompatible with the presence of carbonate. The dolomite inferred here is consistent with the EMOG (enstatite–magnesite–olivine–graphite) buffer[10].

The preservation of the texture illustrated in Fig. 1 is probably dependent on the serpentinization of the host peridotite nodule being predominantly isochemical. An abundance of circulating water would remove both the brucite formed during the serpentinization of olivine in the nodule[11], and that thought to have formed from the decarbonation of dolomite. Fairly widespread serpentinization and removal of relatively soluble brucite from assemblages of the type illustrated in Fig. 1 may explain why the occurrence of these brucite/calcite intergrowths has not been reported before.

The dolomite inferred here to be reflected in the brucite/calcite assemblages probably represents carbonate from a shallower level in the mantle than the source of the kimberlite that brought the host peridotite nodule to the surface[12]. The dolomite may be a product of mantle metasomatism, and whether such meta-

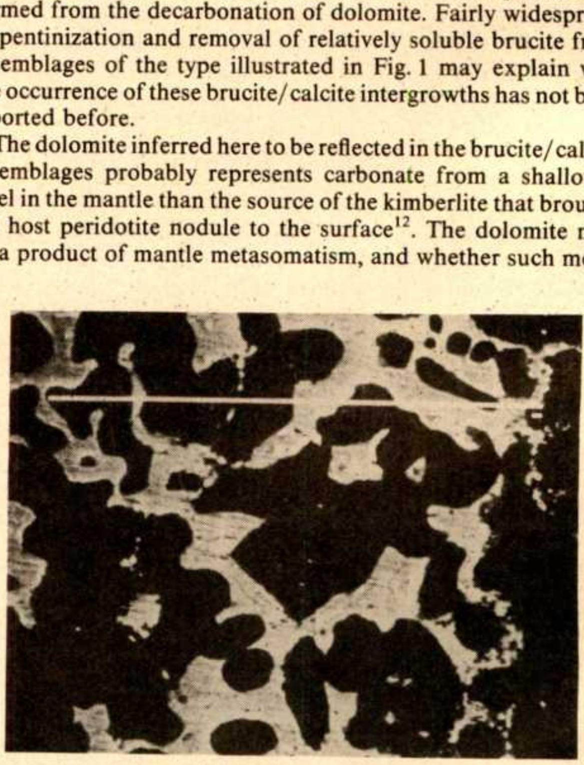

Fig. 1 Electron backscatter image of brucite/calcite intergrowth texture. Calcite (white) and brucite (black) were identified by microprobe analysis on polished thin sections and by X-ray diffraction of separated brucite/calcite grains. An X-ray raster image (not shown) shows traces of SiO_2 in the brucite which are thought to reflect incipient serpentinization. Serpentine was identified in more heavily altered brucite/calcite intergrowths by microprobe analysis. Scale bar, 100 μm.

somatism ultimately reflects plate tectonic processes or merely the interaction of magmas with wall-rock is subject to debate. However, it is suggested that the existence of the brucite/calcite assemblages described here resolves the contradiction of compelling experimental evidence for the presence of carbonate in the mantle with its apparent paucity in mantle xenoliths.

I thank R. S. Rickard and R. Moore for help with analyses on the Cameca microprobe of the Geochemistry Department at the University of Cape Town and the University of Port Elizabeth Research Committee for financial support.

Lahars initiated by the 13 November 1985 eruption of Nevado del Ruiz, Colombia

Donald R. Lowe*, Stanley N. Williams*, Henry Leigh*, Charles B. Connor†, J. Bruce Gemmell† & Richard E. Stoiber†

The eruption of Nevado del Ruiz in Colombia on 13 November 1985 was accompanied by the formation of four lahars (mud flows) triggered by the melting of glacial ice near the summit of the volcano. The lahars began as flows of water, sand and gravel, but they incorporated clay by eroding the soil along the steep valleys through which they passed. The largest flow was a cohesive debris flow, more than 45 m deep and moving at ~12 m s^{-1} when it debouched from the canyon of the Rio Lagunilla 2.5 km from Armero, where it killed 25,000 people. The continuing volcanic activity and abundant remaining glacial ice create an extremely high risk of future destructive flows.

At 5,400 m, Nevado del Ruiz is the highest of a cluster of five volcanic peaks in the Cordillera Central of north-central Colombia (Fig. 1) and is capped by a glacier 2–5 km wide. A major eruption of Ruiz occurred in 1595, and in 1845, Ruiz was the source of a lahar which killed more than 1,000 people at Ambalema (Fig. 1) on the Magdalena River (refs 1–3 and J. B. Tomblin, unpublished work). The recent activity of Ruiz began with earthquakes in November 1984, followed by a small phreatic eruption on 22 December (refs 4, 5, 6 and J. B. Tomblin, unpublished work). A second eruption occurred on 11 September 1985 (ref. 7).

On 13 November 1985, a minor eruption at ~15:00 local time produced a light ashfall north-east of the volcano[8]. Between 21:00 and 21:15 a larger eruption occurred, producing small pyroclastic flows and surges near the summit[9,10] and melting a small part of the summit glacier, which generated four major lahars[8] (Fig. 1). The two most destructive lahars moved eastwards down the Rio Lagunilla and its tributary, the Rio Azufrado, toward Armero; a third moved northeastwards down the Rio Guali toward Mariquita; and a fourth moved northwestwards down the Rio Molinos into the Rio Claro and thence to the Rio Chinchiná toward Chichiná (Fig. 1).

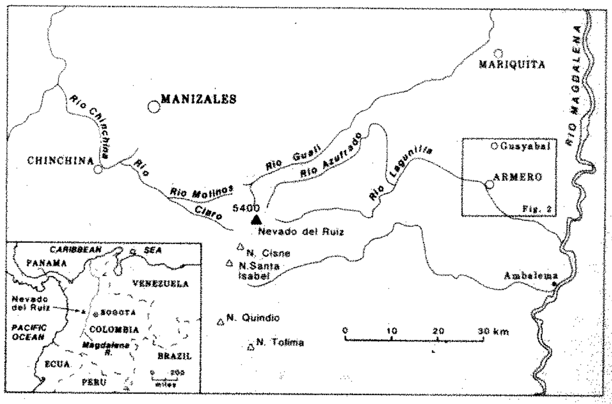

Fig. 1 Generalized location map of Nevado del Ruiz and vicinity, and (inset) Colombia.

Examination of the Rio Guali lahar deposits on the north-east slope of Ruiz, ~5 km from the summit, indicates that the initial flow was a mixture of sand, gravel, water and probably ice, but contained little clay. The main effects of the flow at this point were to strip away a 0.5–2-m-thick layer of vegetation, soil and older pumice overlying massive volcanic rock and to deposit units of coarse, moderately-to-poorly sorted, well-stratified gravel and sand. Most of the clay in the lahars that emerged from the canyons below was evidently derived by erosion of soils along the steep, V-shaped valleys through which the flows passed.

The valleys on the east and north-east side of Ruiz descend from elevations of ~5,300 m to only 400 m, where they enter the Magdalena River valley over river distances of 60–80 km. Headward slopes are generally 10–15°; slopes near the base are generally 3–4°. The lahars stripped vegetation and soil from the canyon walls to heights commonly exceeding 50 m and eroded many older alluvial deposits from the valley bottoms. The Rio Lagunilla flow travelled ~60 km before debouching just west of Armero. Based on a 2-h travel time (initiation at ~21:30 to passage through Armero at 23:30), the estimated mean flow velocity was 8.3 m s^{-1}. The course of the Rio Azufrado flow was 12 km longer than that down the Rio Lagunilla, giving a mean velocity of 10.0 m s^{-1}. Examination of the river valleys, as well as eye-witness reports, indicate that the Rio Azufrado flow was considerably more voluminous than the flow in the Rio Lagunilla, and that the former carried the bulk of the rocky debris. The differences in path-length and composition of these flows suggest that, downstream from the junction of the two rivers, the flows may have passed as a series of two or perhaps more discrete surges. Cross-cutting relationships at the junction of the Rio Lagunilla and Rio Azufrado indicate that the Azufrado flow reached the junction first[11], and may have formed the first surge to inundate Armero. The passage of a small lahar in the Azufrado in September 1985 (ref. 12) may have facilitated the movement of the later lahar.

About 1 km upstream from the canyon mouth, 2.5 km west of Armero, the Rio Lagunilla flows followed a sharp bend to the right, banking high onto the left (north) wall of the canyon (Fig. 2). The mean velocity (w) of debris flows at maximum discharge can be calculated indirectly from their superelevation around bends:

$$w = [g \cos \beta \tan \delta R]^{1/2} \qquad (1)$$

where g is the acceleration of gravity, β is the slope of the stream bed, δ is the slope of the banked flow surface (here measured from differential levels of scour on opposite sides of the river) and R is the radius of curvature of the bend[13,14].

Around this bend, $g = 9.8\ \mathrm{m\ s^{-2}}$, $\beta = 4°$, $\delta = 7.5°$ and $R = 110$ m, yielding a mean flow velocity of $11.9\ \mathrm{m\ s^{-1}}$. The flow was ~45 m deep at mid-channel and had a cross-sectional area of nearly $4{,}000\ \mathrm{m^2}$. The calculated discharge (Q) was $\sim 47{,}500\ \mathrm{m^3\ s^{-1}}$. Similar flows at Mt St Helens in the United States in 1980 had peak velocities of $3.2\text{–}40\ \mathrm{m\ s^{-1}}$ and peak discharges of 2,440 to $>190{,}000\ \mathrm{m^3\ s^{-1}}$ (ref. 15). Most lahars and debris flows attain their maximum depths near the flow fronts[13]. The conditions calculated above probably characterized the first surge of debris to leave the Rio Lagunilla canyon.

The difference between estimated mean flow velocities and that of the initial surge immediately upstream from Armero may reflect imprecise estimates of the times of flow initiation and arrival; down-slope changes in channel geometry and resistance; and down-slope flow evolution from friction-dominated gravel-sand-water slurries to cohesive gravel-sand-clay-water debris flows.

When the lahars left the canyon of the Rio Lagunilla, they emptied onto the gently sloping surface of the west side of the Magdalena River valley (Fig. 3). Within 2 km of the canyon mouth, the Rio Lagunilla is incised 10-15 m below this surface. The initial flow, however, was sufficiently deep that it spread radially from the canyon mouth and split into three main lobes. The northern lobe moved to the ENE, left the Rio Lagunilla, swept through northern Armero following a broad distributary valley, and then turned northward and flowed as a series of anastomosing lobes to within 1.5 km of Guayabal (Fig. 3).

Most of the debris flowed southeastwards, following the broad valley of the Rio Lagunilla. Because the present river lies along the southern edge of this valley, and was too small to accommodate the volume of the lahar, most of the southern lobe moved north of the river, inundating and obliterating the low-lying southern half of Armero. The only parts of the city not completely destroyed were the slightly elevated central and eastern areas between the two main flow lobes. The inertia of the flow carried all but a small part of the debris away from the present river to the south-east and east for nearly 16 km, along a broad alluvial valley which may be an abandoned river course or a route of previous lahars (Fig. 3). A much smaller amount of debris followed the course of the Lagunilla, forming a small third lahar lobe.

Early reports from Armero indicated that many victims were burned, suggesting the possibility that the lahars were hot. Although virtually everyone caught in the flow suffered extensive lacerations because of the abrasive power of the coarse debris, we saw no evidence that the flows were hot. One victim interviewed several weeks after the disaster states that the flows were cold but still burned. The high sulphate content of the flow deposits[16] suggests that the 'burning' was actually caused by the acidity of the flow.

The Lagunillas-Azufrado lahar deposits are generally between 1 and 2 m thick and mantle, rather than fill, pre-flow topography. They cover an area of nearly $32\ \mathrm{km^2}$, which, for an average depth of 1.5 m, implies a volume of $\sim 4.8 \times 10^7\ \mathrm{m^3}$. The deposits consist of grey, dense, massive, extremely poorly sorted clayey gravelly sand. Granulometric analysis of one sample from the upper part of the proximal flow deposits 0.5 km south-east of the canyon mouth shows (by weight) 47.9% sand, 27% gravel, 17.5% silt and 7.6% clay. All the coarser debris is composed of lithic volcanic rock types; fresh pumice was not identified. Clasts ≥ 50 cm in diameter are generally rounded and probably eroded from older alluvial deposits. Clasts <15 cm in diameter are commonly matrix-supported.

The grain-size structuring of the deposits indicates that, within the debris flows, the mixture of fluid and granular materials ≤ 10 cm in diameter behaved as a homogeneous phase in which there was no separation or differential settling of constituents. Clasts ≥ 15 cm across, locally reaching 10 m in diameter, occur only at the base of the lahar deposits. They were either transported at the bases of the flows or settled as the flows decelerated. As a result, many of the deposits show normal grading of the coarsest constituents.

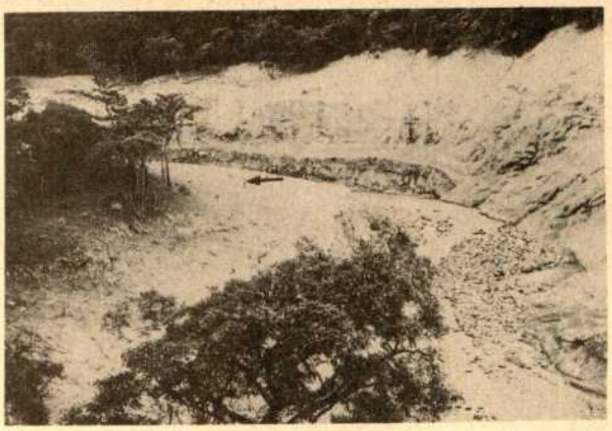

Fig. 2 Photograph of the Rio Lagunilla canyon looking upstream, ~2.5 km from Armero and 1.5 km upstream from the mountain front. Lahars generated by the 13 November 1985 eruption of Nevado del Ruiz have stripped vegetation and soil from the lower parts of the canyon walls and deposited a thin veneer of mud. A man (arrowed) gives the scale. The superelevation of the flow along the north bank (the right bank in the photograph) can be seen.

The observations that the flow deposits mantle, rather than fill, the topography and show differential settling of larger clasts suggest that the strength of the flow was relatively low. Flow strength (k) can be estimated by[13]:

$$k = T\rho_f g \sin\alpha \qquad (2)$$

where T is the deposit thickness, ρ_f is the flow density and α is the slope of the deposit surface[13]. Over broad areas, $T \simeq 100\text{–}150$ cm and $\alpha < 1.4°$, and ρ_f is taken as $2.2\ \mathrm{g\ cm^{-3}}$. For these deposits, $k \simeq (5.3\text{–}8.0) \times 10^3\ \mathrm{dyn\ cm^{-2}}$, which is comparable to that of many other debris flows[13,17].

The large volume of glacial ice remaining on Nevado del Ruiz after 13 November, the abundance of debris around the summit, and the precipitous, narrow gorges leading downward to river valleys around the volcano collectively represent ideal conditions for the formation and long-distance movement of lahars.

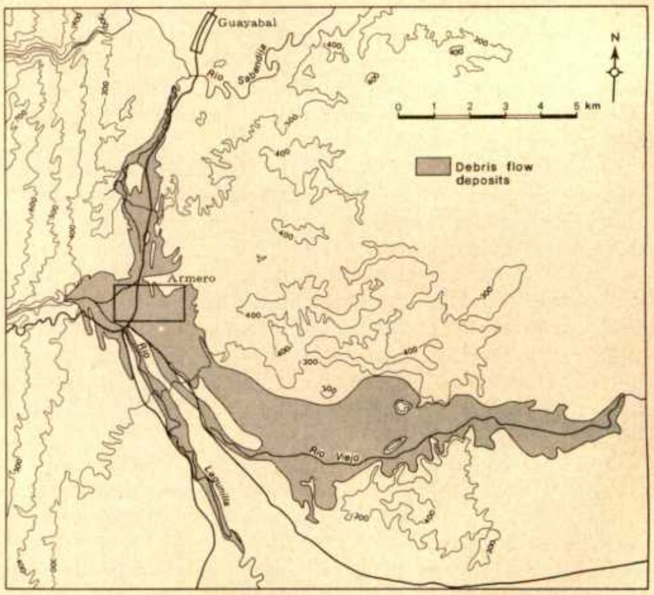

Fig. 3 Map of the Armero region (box in Fig. 1), showing the distribution of the deposits of the Rio Lagunilla lahar.

It is clear that the volcano is presently active and the probability of future eruptions is high. Even minor volcanic activity would inevitably trigger new lahars. Appropriate measures for early detection and hazard mitigation should be taken.

Sporadic shutdown of North Atlantic deep water production during the Glacial–Holocene transition?

W. H. Berger* & E. Vincent†

* Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, USA
† Scripps Institution of Oceanography and Département de Géologie Dynamique, Université Pierre et Marie Curie, 75005 Paris, France

Pulsations in the production of North Atlantic deep water (NADW) have been implicated in generating drastic climatic fluctuations during the Glacial–Holocene (G/H) transition[1–3]. The stable isotope record of benthic foraminifera in high-resolution cores from the Norwegian Sea suggests that such pulsations did occur[4]. Although the question of exact timing (and mechanism) is still open there is little doubt that NADW pulsations were important in climatic history because the rate of NADW production influences the rate of advection of heat to the northern North Atlantic[5]. Here we report that a sporadic shutdown of NADW may be recognizable in deep-sea carbonates with normal (low) sedimentation rates. Hence the possibility arises that relatively short-lived events (~1,000–2,000 yr) in deep circulation can be mapped over large areas of the sea floor, despite the detrimental effects of bioturbation on signal resolution.

The overall pattern of deep circulation in the present ocean is characterized by the asymmetry in deep-water properties of the Pacific and the Atlantic, which reflects the difference in age between sub-thermocline waters and, in essence, results from NADW production. We have chosen four cores to reconstruct the sequence of deep-water age difference in the two oceans since maximum glaciation (Fig. 1): ERDC 112 Bx, ERDC 123 Bx, INMD 113 Bx, and INMD 115 Bx. The ERDC box cores are from the Ontong Java Plateau in the western equatorial Pacific, from depths of 2,169 m and 2,948 m, respectively. Isotope stratigraphies and details on sedimentation rates and physical properties have been given elsewhere[6,7]. The INMD box cores are from the Mid-Atlantic Ridge, at 15.5 and 17.4° S, and from depths of 3,471 m and 3,427 m, respectively. Core data are given in ref. 8 and isotope data are listed in Table 1. Core ERDC 112 Bx and the INMD cores are close to the present two-degree potential temperature level[9]. The INMD sites are within the high-salinity-core layer of (lower) NADW. The ERDC sites sample general Pacific deep water with average salinity.

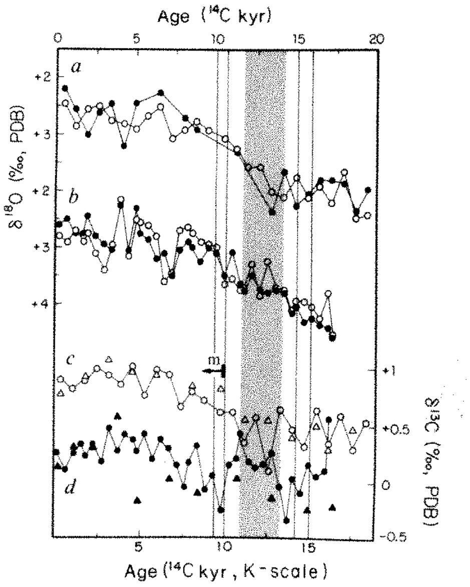

Fig. 1 Oxygen and carbon isotopes in the shells of benthic foraminifera from deep-sea sediments in the central Atlantic and western equatorial Pacific. Age scales are based on radiocarbon datings of bulk sediment (top-scale, refs 7, 8) and on correlation of planktonic oxygen isotope signals with the Norden (radiocarbon-) timescale (bottom scale, ref. 18). *a*, $\delta^{18}O$ values for *Cibicidoides wuellerstorfi* (○) and *Oridorsalis umbonatus*, adjusted by −0.6‰ (●), in core INMD 115 Bx, Atlantic. *b*, $\delta^{18}O$ values for *C. wuellerstorfi* (○) and *O. umbonatus*, adjusted by −0.75‰ (●) in core ERDC 112 Bx, Pacific. *c*, $\delta^{13}C$ values for *C. wuellerstorfi* in cores INMD 115 Bx (○) and INMD 113 Bx (△), Atlantic; m over arrow, appearance of *Globorotalia menardii*. *d*, $\delta^{13}C$ values for *C. wuellerstorfi* in cores ERDC 112 Bx (●) and ERDC 123 Bx (▲), Pacific. Atlantic data from Table 1, Pacific data from ref. 6.

The benthic foraminifera analysed are *Cibicidoides wuellerstorfi* and *Oridorsalis umbonatus*. Both species were used for plotting $\delta^{18}O$ values, but only *C. wuellerstorfi* was used for the carbon isotope record. We believe[10,11], as do others[12–16], that this species best reflects the $\delta^{13}C$ content of deep waters, with a minimum of interference from vital effects and contamination by interstitial values of $\delta^{13}C$. Analyses were carried out as described in ref. 17.

The oxygen isotope record in the deep Atlantic (INMD 115 Bx, Fig. 1*a*) shows the rise from heavy to light oxygen isotope values during the G/H transition, which is largely due to the addition of meltwater. The change occurs mostly between 14,000 and 8,000 yr BP; the G/H range is between 1.3 and 1.4‰. Of the two foraminifera, *C. wuellerstorfi* is plotted as measured, while the values for *O. umbonatus* are adjusted by −0.6‰ to make them congruent. Exact ages cannot be assigned because of the effects of resedimentation and bioturbation on radiocarbon dates; a measure of uncertainty is

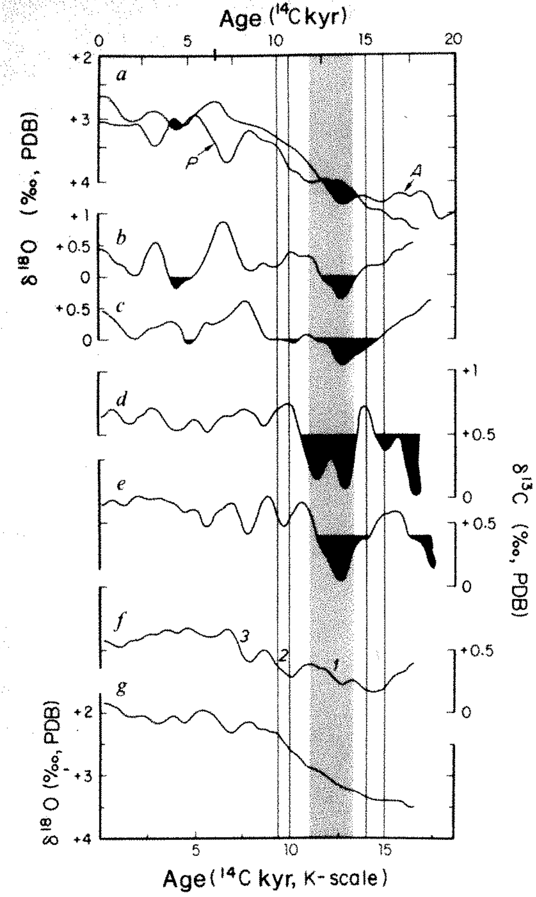

Fig. 2 Smoothed curved (triangle filter, 12321) derived from data in Fig. 1, *C. wuellerstorfi* in INMD 115 Bx (Atlantic) and in ERDC 112 Bx (Pacific). *a*, δ^{18}O values in Atlantic (A) and Pacific (P); black areas: P-values lighter than A-values. *b*, Difference in δ^{18}O values Atlantic – Pacific; black: difference negative. *c*, As *b*, after shifting Pacific curve to right by 1,000 yr. *d*, Difference in δ^{13}C values Atlantic – Pacific; black: difference $< +0.5$‰. *e*, As *d*, after shifting Pacific curve to right by 1,000 yr. *f*, Average of Atlantic and Pacific δ^{13}C curve. *g*, Average of Atlantic and Pacific δ^{18}O curve.

given by the alternative timescales shown. The timescale on top is the best-guess scale derived from bulk radiocarbon ages as listed in ref. 8. The timescale on the bottom[18] is derived from a correlation of the oxygen-isotope signal with the climate-stratigraphy of the Norden scale[19]. The stippled pattern denotes the timespan for which sporadic shutdown of NADW is proposed.

A similar oxygen isotope plot for the Pacific (ERDC 112 Bx, Fig. 1*b*) shows a noisier record (possibly because of lumpy bioturbation in this more productive area) but otherwise reflects the same transitional change. *Oridorsalis umbonatus* in this record was adjusted by −0.75‰. The greater difference between the two foraminiferal species may be a function of the higher productivity in the Pacific. The G/H range, here too, is ~1.4‰. If a range of 1.2‰ is accepted for the ice-effect[20] then the remaining 0.2‰ would suggest that glacial deep waters were roughly 1 °C colder than postglacial ones, in both oceans. The main conclusion from the oxygen isotope records is that fully glacial conditions were reached at the bottom of each of the box cores, and that the transition is well represented, apparently without hiatus.

The carbon isotope records show the Pacific/Atlantic asymmetry referred to above, with lighter δ^{13}C values in the deep Pacific, which reflects the older age of the water masses there (Fig. 1*c*,*d*). For the past several thousand years the difference in δ^{13}C is close to 0.6‰, as expected from direct measurement of water samples in the present ocean[21]. This corresponds to an age difference of ~600 yr (0.1‰ in δ^{13}C being equivalent to ~100 yr (ref. 11)). The difference persists back to ~10,000 yr BP, suggesting that there has been no major reorganization of deep circulation within this timespan. The records confirm the diminished importance of Atlantic deep-water production during glacial time, an hypothesis put forward previously on the basis of heat budget considerations[22] and benthic isotope data similar to ours[23-26].

Within a narrow time interval during deglaciation proper (the shaded zones in Figs 1 and 2) differences in δ^{13}C values sometimes disappear. We propose that this is the result of a shutdown of NADW. The decrease in Atlantic/Pacific δ^{13}C contrast during deglaciation owes as much to anomalously heavy values in the Pacific foraminifera as it does to anomalously light values in the Atlantic. It is conceivable therefore that an effect besides NADW production has to be considered in this context, namely North Pacific deep water production (see ref. 27). It is difficult to explain these anomalies as the result of bioturbation, because first, the δ-values in question are at the limit of the total range (how could mixing produce extremes?) and second, anomalous values in both Atlantic and Pacific coincide although correlation between the cores is independent of the δ^{13}C-stratigraphies.

The point at which NADW production sets in fully and permanently, at the beginning of the Holocene, is marked by the reappearance in the Atlantic of the previously regionally-extinct planktonic foraminiferan *Globorotalia menardii* (Fig. 1*c*). The coincidence between the two events may be more than fortuitous. The sinking of NADW in the Norwegian Sea implies transport of surface water across the Equator. According to Gordon[28] this water is mainly transported around the Cape of Good Hope, from the Indian Ocean, after southward flow through the Mozambique Channel. This southward flow carries tropical fauna. Thus, the beginning of NADW production favours the reseeding of the tropical foram *G. menardii* in the Atlantic, through the entrainment of tropical Indian Ocean fauna by a strengthened Agulhas Current. During glacial conditions the southward flowing current in the Indian Ocean was weakened, and colder[29,30] and was not effective in conveying *G. menardii* to the Cape. Also, entrainment around the Cape was diminished.

The δ^{13}C values show an overall Glacial to Holocene shift from light to heavy of between 0.4 and 0.5‰ (Fig. 1*c*,*d*). Such a shift is expected from the buildup of organic carbon in the terrestrial biosphere and in soils (Shackleton's 'rain forest' effect[31]). The biosphere build-up preferentially extracts isotopically-light carbon from the ocean/atmosphere system, leaving the ocean enriched in ^{13}C. A late Holocene shift towards lighter values is evident, which we ascribe to biomass destruction (desertification) following the climatic optimum.

As long as the NADW production takes place, the deep Atlantic should remain warmer than the deep Pacific[9]. If NADW production shuts off, the temperature in the deep Atlantic should fall and reach values more like those in the Pacific. To test this possibility we have superimposed the Pacific and Atlantic oxygen isotope data, after smoothing with a five-point triangle filter (Fig. 2*a*). For the past 10,000 yr the Pacific record shows the heavier (colder) values, although not the full difference expected, because of the shallower water depth of the sample cores in the Pacific (2,169 m versus 3,427 m in the Atlantic). The only time when this Atlantic/Pacific contrast reverses sign is in the early part of deglaciation, during the same interval in which the δ^{13}C difference tends to disappear sporadically. Thus, the hypothesis of NADW shutdown is supported by the oxygen isotope record.

The observed reversal of the oxygen isotope difference in the early stage of deglaciation is quite robust towards changes in timescale (that is, towards miscorrelation of the records)—see Fig. 2*b*,*c*. Figure 2*b* shows the record of the δ^{18}O difference seen

in Fig. 2*a*. If one assumes that the Pacific record should be shifted to the right by 1,000 yr to minimize the Pacific/Atlantic contrast, the reversal during early deglaciation still persists. A substantial (and unrealistic) shift of the Pacific record to the left, would be necessary to make this reversal disappear. The carbon isotope anomalies in the Pacific/Atlantic asymmetry are likewise quite robust towards miscorrelation (Fig. 2*d*,*e*).

When averaging the carbon isotope records (ERDC 112 Bx and INMD 115 Bx) an indication of stepwise change during deglaciation becomes apparent (steps labelled 1, 2, 3 on Fig. 2*f*). These steps may reflect abrupt changes in the deep-water carbon composition of the world ocean. It is interesting that they correspond to the major warming episodes proposed in the Norden scheme[19]. If these carbon shifts are due to storage of isotopically-light carbon in forests (and soils) one would then conclude that the deglacial growth of the biosphere proceeded in lockstep with the fluctuations in climate, each major warming episode producing a major increase in biosphere storage. The process would have started ~13,000 yr ago.

The average oxygen isotope record (Fig. 2*g*) shows a gradually accelerating change from the heavier glacial values to the Holocene ones, with a G/H range near 1.4‰. Substantial pre-13 kyr deglaciation[32,33] is not evident in this benthic signal. Instead, these data support a late-deglaciation model[18,34]. Such a model strengthens the case for sporadic shutdown of NADW because a high rate of meltwater influx and of warming tends to prevent the sinking and downward mixing of surface waters in the North Atlantic, during deglaciation[1].

This research was supported by NSF grant OCE85-01578. We acknowledge discussions with J.-C. Duplessy, L. Labeyrie, and N. Shackleton, on carbon isotope stratigraphy of the late Pleistocene ocean. Analyses of the $\delta^{18}O$ and $\delta^{13}C$ values were carried out at Scripps Institution of Oceanography under the supervision of J. S. Killingley.

Giant subtidal stromatolites forming in normal salinity waters

Robert F. Dill*, Eugene A. Shinn†, Anthony T. Jones‡, Kevin Kelly‡ & Randolph P. Steinen§

We report here the discovery of giant lithified subtidal columnar stromatolites (>2 m high) growing in 7–8 m of clear oceanic water in current-swept channels between the Exuma Islands on the eastern Bahama Bank. They grow by trapping ooid and pelletal carbonate sand and synsedimentary precipitation of carbonate cement within a field of giant megaripples. The discovery is important to geologists and biologists because similar organo-sedimentary structures built by a combination of cementation and the trapping of sediment by microbes were the dominant fossil types during the Precambrian. Stromatolites are thought to have been responsible for the production of free oxygen and thus the evolution of animal life[1,2]. Until the discovery of small lithified subtidal columnar stromatolites in the Bahamas[3], the only subtidal marine examples known to be living while undergoing lithification were

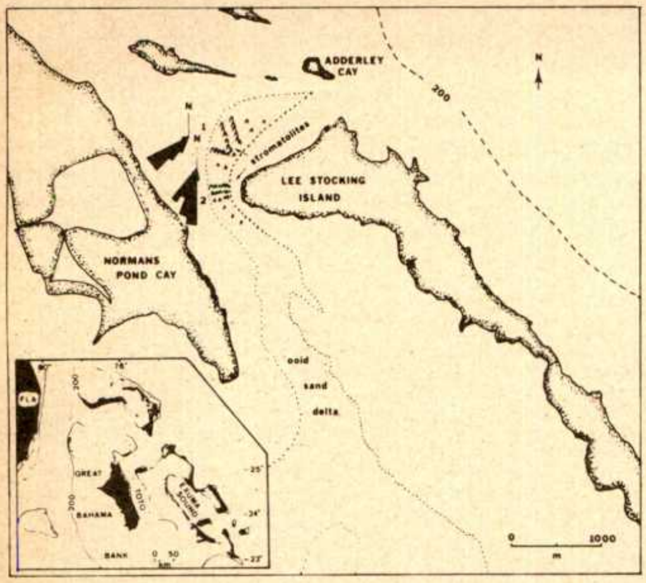

Fig. 1 Location of stromatolite-bearing tidal channel north and west of Lee Stocking Island, Exuma Cays, Bahamas. Rose diagrams are plots of the long axis of streamlined stromatolites that parallel the main axis of tidal flow in the channel: 1, 044–266° ($N=31$); 2, 014–194° ($N=60$). Orientation measurements of stromatolites were made with underwater Brunton at stations numbered 1 and 2. Visual observations demonstrate that many of the streamlined stromatolites are tilted toward the incoming tidal bottom currents. Contours in metres.

in the hypersaline waters of Hamelin Pool at Shark Bay, Western Australia[4–7]. Shark Bay stromatolites range from intertidal to the shallow subtidal with the larger columns reaching 1 m in height. The Shark Bay stromatolites have strongly influenced geological interpretation; by analogy, many ancient stromatolites have been considered to have grown in intertidal and/or hypersaline conditions[8], although hypersalinity was not a necessity for growth during the Precambrian because grazing metazoan life had not then evolved.

Stromatolites from the Exuma Islands occur in one of the many channels that exchange normal oceanic water from the deep Exuma Sound through the Pleistocene eolianite islands to the shallows of the eastern Bahama Bank. Those described here are from the channel separating Lee Stocking Island from Adderley and Normans Pond Cays (Fig. 1). The Exuma Islands are well known to carbonate geologists for their spectacular eolian carbonate dunes and ooid tidal deltas[9,10]. Exuma Sound has precipitous margins and a maximum depth of ~1.5 km. The eastern portion of Exuma Sound is open to the Atlantic Ocean and its waters which flood the stromatolites at high tide are exceptionally clear and of normal oceanic salinity (37–38‰). Underwater visibility in the tidal channel during flood tide is often >20 m. Ebb tidal waters from the shallow banks are more saline (as much as 40‰) due to evaporation, and have a visibility of 5–10 m, depending on weather conditions. Tides are diurnal and create currents between islands ranging between 60 and 100 $\mathrm{cm\,s^{-1}}$.

To date, we have found growing stromatolites only associated with migrating 1- to 2.5-m-high ooid sand dunes. The stromatolites occur as individuals or as large, coalesced bioherms that form rows perpendicular to tidal flow (Fig. 2) and as randomly-spaced individuals of variable height. Randomly-spaced individuals are usually grouped in irregular-shaped patches 5–10 m across. The tops of the larger fence-like stromatolites are parallel with the crests of submarine sand dunes. Nearly all individuals, regardless of size, are streamlined by tidal currents. Many display higher growth rates on the side facing the incoming tide, which causes them to lean noticeably towards the clear water.

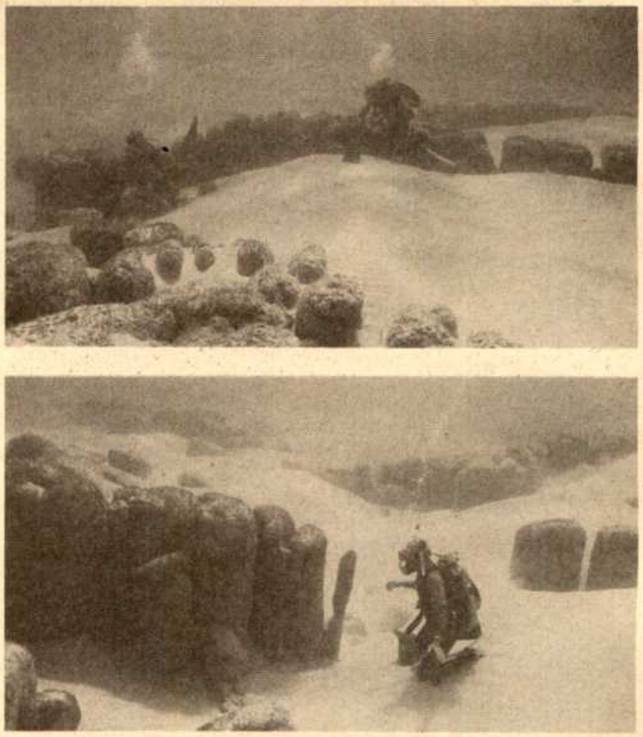

Fig. 2 Two views of large aligned fence-like stromatolites. Note that the height of migrating rippled oolitic sand dunes (megaripples) just equals the height of stromatolites and hence periodically covers most stromatolites. Smaller stromatolites in foreground of upper photograph are populated by the green alga *Batophora* spp. *Batophora* is uncommon or absent from actively growing specimens, such as in Fig. 3*a* and *c*, and those recently uncovered by migration of oolitic megaripples and bars. Photo taken at slack tide at a water depth of 7 m.

Many larger stromatolites have a soft botryoidal or pustular surface (Fig. 3*a*). Individual 1- to 10-cm-diameter botryoids are composed of uncemented ooid sand loosely bound by mucus and unidentified microbial filaments (Fig. 3*b*). Small stromatolites as much as 1 m high may also have a pustulate surface, but most are smooth and slightly elongate (streamlined) parallel to tidal currents. The surfaces of the small smooth individual are usually hard or crusty and lack the loosely held sand coating (Fig. 3*c*). Microbial filaments (Fig. 3*b*) occupy only the upper 2–4 m of the soft growth zone.

'Micro-atoll'-shaped stromatolites are also common. Micro-atolls are stromatolites with a central depression and an elevated rim, the central depressions being 10–30 cm deep and often filled with rippled oolitic sand. During maximum tidal flow, sand, shells and intraclasts swirl in the central depressions like pebbles in stream potholes. Whether the depressions are erosional features or are caused by growth of the rim has yet to be determined.

Where the channel turns southward (Fig. 1), the megaripples lose relief and the stromatolites become smaller. In this area the coalesced forms become S-shaped to form rows perpendicular to currents but with low relief, <1 m, and in plan view resemble Arabesque ornamentation. Circular micro-atolls interspersed with these shapes suggest they result from coalescence and erosion of semi-circular micro-atolls.

Staining experiments confirmed that stromatolites can grow rapidly. Three specimens were stained *in situ* with Alizarin Red S by injecting the solution into a clear inverted plastic bag cinched tightly around the base of each specimen. The bag and stain were removed after 6 h. Twenty-four h later, a layer of sand ~1 ooid thick (200 μm) had been deposited over the stained surface; sediment also adhered to vertical sides. Diver observation and underwater video documentation showed that most

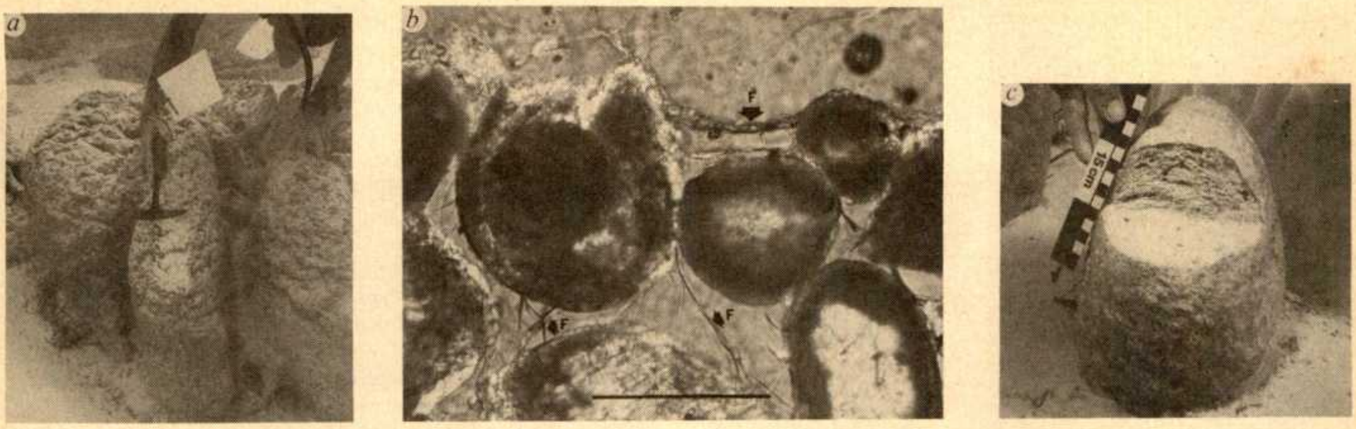

Fig. 3 *a*, Actively growing stromatolites with soft pustulate surface. *Batophora* or other epibionts are absent from surface of actively growing stomatolites. White patch below hammer caused by scraping away the soft uncemented surface layer, which is held in place by microbial filaments. Sand thrown against vertical sides by diver will stick to form a layer $\sim$1 ooid thick. *b*, Thin-section photomicrograph of growing uncemented upper surface of pustulate stromatolite. Note tiny microbial filaments (F) responsible for trapping of grains. Large grain is an ooid. Other grains are hard peloids. Note how filaments coalesce to form horizontal mat over growth surface (arrow). Growth of the internal filaments is normal to the surface. Section prepared by preserving pustule in ethyl alcohol, followed by desiccation in oven and vacuum impregnation with polyester resin. Specimen photographed under crossed polars using a gypsum plate to emphasize microbial filaments. Portion of ooid grain was plucked during preparation but algal mat shows original surface of the ooid. Scale bar, 200 μm. *c*, Underwater photograph of smooth surface of streamlined stromatolite which has been sawed with a hand saw. Note internal laminations, lack of pustules as shown in *a*, and lack of crenulations in convex-upward laminae. Ooid sand megaripple in background partially covered specimen 24 h later.

stromatolites are dusted with ooid sand during each tidal cycle and sand thrown against vertical surfaces by a diver sticks instantly to form a layer. A shell (*Strombus gigas*) from the base of a 50-cm-high specimen at a depth of 8 m gave a ^{14}C age of 480 ± 50 yr BP. The green alga *Batophora* sp., thought by Dravis[3] to be significant in stromatolite growth, was not found on the stromatolites studied here. The organic mat responsible for trapping suspended ooids and biogenic sands is a complex consortium of blue-green algae, specially adapted diatoms and as yet unidentified plants and organisms. The composition probably varies with season and time when buried columns are re-exposed. It is significant that the micro-ecosystem has adapted to high-energy conditions with life forms having 'sticky flypaper' surfaces that trap sand grains, which, in turn, on stabilization, protect the mat from further bombardment by suspended grains.

In areas near the sides of the channels, ooid sands have been stabilized by marine grasses, and sand saltation does not occur. The stromatolites in these areas are densely populated by grazing fish and epibionts such as *Acetabularia*, *Batophora*, *Sargassum*, *Siderastrea* spp. and a variety of unidentified sponges and crustose calcareous algae. Most have been invaded by boring pholad clams, and the boring sponge *Cliona* spp. has attacked many specimens; these stromatolites appear to be relict forms that are being destroyed by bioerosion.

The internal structures of dissected columns are strikingly similar to Precambrian forms and consist of convex-upward laminations composed of ooid and pelletal sand. Laminae are caused by a combination of variations in grain size, cementation and alignment of pores. Some columns have incorporated siliceous spicules. The laminations occur in two styles: nested small-scale convex-upward laminations that form 1- to 4-cm-wide columns, and larger convex-upward laminations that encompass the large portions of columnar stromatolites (Fig. 4). The smaller columns, often separated by unlaminated cemented sand, are superimposed on the larger scale laminations. Many laminations thin towards the edges of the stromatolite and in places are truncated by near vertical wall structure along the sides of the more columnar stromatolites (Fig. 4). Larger stromatolites have not been sampled, but it is thought they may be composed of both small and large columns as much as 1 m high or more. The maximum synoptic relief determined by using any one lamina in the stromatolite structure (Fig. 4) is only 16 cm, whereas the total exposed relief of the structure itself is $>$45 cm; maximum synoptic relief of the small-scale column is $<$1–2 cm.

Voids are numerous, and whereas some are borings, others are constructional. Borings, whether excavated by pholads, serpulids, or sponges, are characterized by truncated grains and cement, and except for those made by pholads, they tend to be irregular in shape and orientation. Constructional voids are planar and parallel local laminations. Grains and cement are not truncated by constructional planar voids; these can form when fleshy epiphytes such as sponges and the alga *Batophora* sp. are entombed by subsequent deposition of laminated sand. The organism decays and a void, essentially parallel to depositional laminae, is formed and preserved by rapid cementation. Finer grained sand and silt may form geopetal fillings in both kinds of voids, which often contain uncemented ooids.

Marine cementation is rapid in this ooid-forming environment, and a portion of the Bahama Bank a few kilometres west of the Exuma Islands is where the process was first documented in the Bahamas[11]. Cementation of the stromatolites is similar to that in Shark Bay[12]. Uncemented ooid sand at the surface transitionally changes to hard limestone in the interior. The gradient from organically-bound sediment to rock extends from the upper surface to a depth of 4–5 cm and is best appreciated by sawing vertically into a stromatolite with a carpenter's hand saw; sawing begins easily but slows and becomes impossible beyond 30 cm as cementation increases.

The cement is mainly acicular aragonite, similar to that observed in other areas of marine cementation. In localized areas, aragonite crystals are tightly bundled to form what has been termed acicular fan druses[13] or botryoidal aragonite[14]; the latter occurs as a partial filling in voids. Micrite-textured Mg calcite is patchy and is more common in finer grained geopetal internal sediments. Magnesian calcite also occurs as cryptocrystalline cement in 20- to 25-μm-diameter tubules[3]. Because of their habit of penetrating both pore space and grains, Dravis[15] defined the tubules as chasmolithic/interolithic algae, probably of the genus *Ostreobium*. We are unsure of their actual affinity of the timing of their entry into the stromatolite matrix. They are not common in the uncemented growth zone and thus are not considered significant as primary sediment trappers. Additional study is needed to determine when and how they invade stromatolites and become diagenetically altered to micritic Mg calcite.

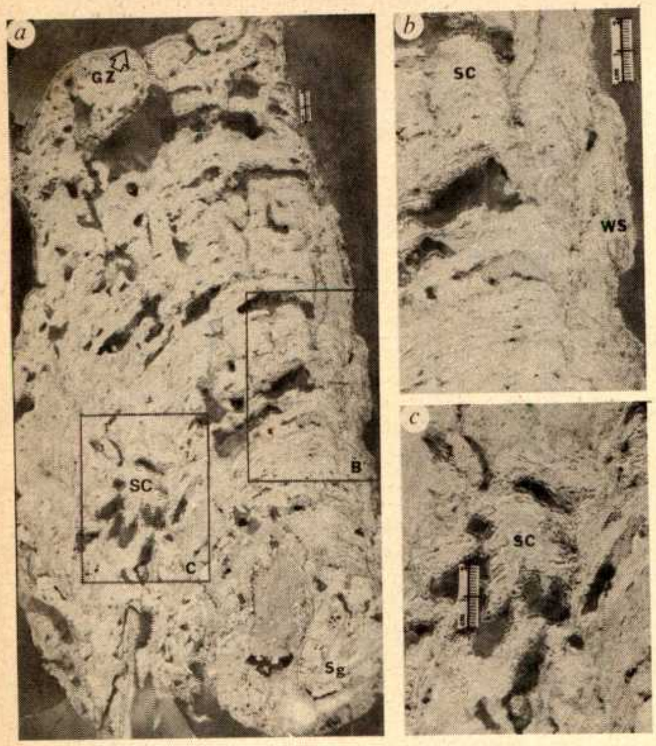

Fig. 4 Views of plastic-impregnated specimen which was cut in half to reveal internal structure. The slab is oriented so that incoming tide flowed from right to left. *a*, Slabbed plastic-impregnated specimen is 45 cm high and nucleated on a conch (*Strombus gigas*) shell (Sg). Note the small-scale convex-up laminations (SC) which form columns radiating from the base. Small-scale laminations are actually upward continuations of crenulations in larger scale laminations. Wall structure (WS) is shown in inset (*b*). Larger plastic-filled voids are borings; however, void around and below SC in inset (*c*) is thought to have been formed when a fleshy epibiont rotted away. GZ (top of *a*) shows soft uncemented pustular growth zone where grains are trapped and bound by the algal filaments shown in Fig. 3*b*. The small-scale columnar structure is thought to be caused by upward growth of pustules such as shown here. Unlaminated areas are former voids which have been filled with oolitic sand.

Bahamian subtidal stromatolites provide a new set of environmental parameters to use in interpreting spatial distribution of ancient stromatolites, orientation, water depth, salinity, constraints on growth forms and the timing of cementation and mineralization. For example, due to the Shark Bay modern analogue, most authors have regarded ancient stromatolites as intertidal in origin, although some have subtidal affinities or large size, which necessitated postulating enormous paleotidal fluctuations[8]. Modern subtidal stromatolites have been reported before[3,6,16,17] but unfortunately seem to have had little influence on the mainstream of geological interpretation. The Bahamian examples described here are by far the deepest and largest to be reported from the Holocene and hopefully may help clarify the many debates concerning salinity, current regimen, and depositional water depth of ancient stromatolites. Ancient stromatolites, like modern ones, were not limited to intertidal or hypersaline conditions, and many authors recognized this as a fact based on geological interpretation[8,18–20]. The Bahamain stromatolites provide an alternative for palaeoenvironmental comparative studies.

In the Holocene and probably throughout much of Phaerozoic time, grazers and borers prevented stromatolite growth and preservation in normal marine subtidal waters. During the Precambrian, however, there were no known grazing and boring organisms, and stromatolites flourished uncontested for $>2\times10^9$ yr. Without competition, Precambrian stromatolites freely populated enormous areas[20,21], and probably grew in water depths >10 m (ref. 8). Strong tidal currents were not a necessary requirement for growth and preservation in the Precambrian before the evolution of higher life forms. We anticipate that future comparative research on these Holocene stromatolites will provide many additional clues for interpreting depositional environments and the processes that moulded the shapes and distribution of ancient stromatolites of all ages.

We are grateful for the support and facilities at Lee Stocking Island provided by the Caribbean Marine Research Center. We acknowledge the support of Mr Robert Wicklund, Ms Geraldine Wenz, and Mr John H. Perry Jr, owner of Lee Stocking Island. Partial support was provided by the Office of Undersea Research, National Oceanic and Atmospheric Administration, US Department of Commerce. Ralph Knight is thanked for piloting us. We thank Richard Wilkens, Thomas Lorensen and Tom Judy for underwater support, field and laboratory help in this unfunded research. Barbara Lidz provided editorial assistance. We also thank Sal Valestro at the Balcones Research Center of the University of Texas for dating the conch shell and R. N. Ginsburg, Richard Slater and Christopher Kendall for field assistance and stimulating discussion. Finally, we thank J. H. Hudson for guidance, equipment and chemicals for staining stromatolites *in situ* and Renato Diaz for sample and thin section preparation, and photoprocessing.

Sex-ratio manipulation in the common opossum

Steven N. Austad & Mel E. Sunquist*

The idea that offspring sex ratio is affected by parental capacity for reproductive investment was first developed by Trivers and Willard[1] and later elaborated by others[2–6]. According to this hypothesis, if the amount of parental investment[7] differentially affects the expected reproductive success of offspring depending on offspring gender, then parents capable of exceptionally large investment should bias reproductive investment toward the sex affected most. For most polygynous mammals, male reproductive success is expected to be most enhanced by exceptionally large investment[1,8], but observational field studies and laboratory experiments have either supported[9–13] or contradicted[3,14–16] this conditional sex-allocation hypothesis. We have performed the first

experimental field study specifically to examine this hypothesis, and find that the female common opossum (*Didelphis marsupialis*), whose capacity for parental investment was artificially enhanced by dietary supplementation, produces male-biased sex ratios, in contrast to the unbiased ratios produced by control females.

The conditional sex-allocation hypothesis holds that variance in reproductive success is expected to be greater among males than among females in polygynous animals because some males have more than one mate whereas other males have no mates. Consequently, because high-quality males will have greater reproductive success than any single female, females producing high-quality offspring will have more grand offspring if they produce males. Conversely, low-quality offspring should be female, because essentially all females find mates.

The common opossum, a polygynous marsupial[17], exhibits no paternal care. Young are born after 13 days' gestation in an embryonic state and complete development during 60–70 days in the maternal pouch. During a 2-year study near Calabozo in the central Venezuelan savanna, we trapped, weighed, radio-collared and released 40 adult virgin females (virgins can be identified by the condition of their pouch[18]) before the onset of the breeding season. Half of these females were randomly assigned to control and half to experimental groups. Two controls died before the start of breeding and are not included in the results. Experimental animals were located in their day time sleeping dens and provisioned with ~125 g sardines every 2 days from at least 2 weeks before any pouch young appeared until the end of the breeding season. Provisions were placed at the mouth of their dens near dusk when the animals become active. Provisioning was intended as a supplement to, and not a substitute for, a normal diet. Both controls and provisioned animals were recaptured, weighed and the size and sex of their pouch young recorded approximately once per month.

Pouch young can be toe-clipped and sexed visually at about 10–15 days of age when they weigh only ~1 g (<0.1% of maternal body weight). The course of pouch-young development in opossums has been extensively studied[18–20], so that from a combination of anatomical features the animals can be aged to within 5 days for their first month in the pouch.

We found that provisioned females have no more offspring than controls (Table 1), but their individual offspring are significantly larger at all stages of development from 20 days of age until they left the maternal pouch (Fig. 1). Thus, provisioned females exhibit greater total parental investment than controls. The recapture rate of independent juveniles supports the contention that the offspring of provisioned females survived better than controls (Table 1).

Table 1 Maternal investment in control versus provisioned females

	Control	Provisioned	P-value
Maternal weight (kg) at start of experiment ($\bar{X}\pm$s.e.m.)	1.38±0.07	1.37±0.07	0.71 ($t_{36}=0.314$)
Litter size ($\bar{X}\pm$s.e.m.)	7.52±0.36	7.61±0.34	0.56 ($t_{36}=0.142$, one-tail)
Pouch young mortality (%) from age <15 days to >45 days			
Males	2.3 (87)	4.5 (111)	0.30
Females	2.3 (87)	5.2 (77)	0.22
Total	2.3 (174)	4.8 (188)	(G test)
Weaned young recaptured (%)			
Males	16.4 (55)	44.4 (54)	0.001
Females	12.8 (47)	28.9 (45)	0.054
Total	14.7 (102)	37.4 (99)	0.0002 (G test)

Numbers in parentheses, total number in sample.

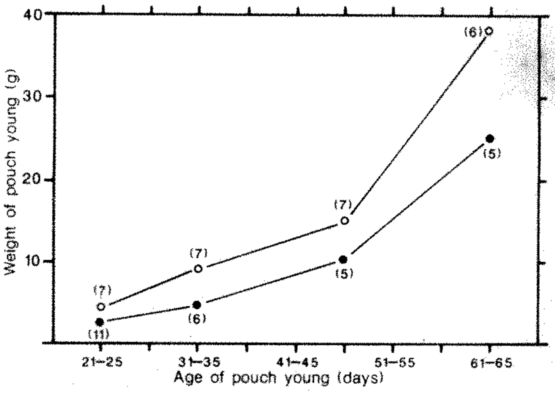

Fig. 1 Difference in weight of pouch young between provisioned (○) and control (●) females. Data from all 5-day periods during which at least 5 females from both groups were captured. Weight differences are statistically significant for all comparisons (Wilcoxon rank sum tests: 21–25 days, $P=0.038$; 31–35 days, $P=0.007$; 46–50 days, $P=0.015$; 61–65 days, $P=0.026$). No. of females in each sample in parentheses. Fifteen females from both provisioned and control groups are represented. Samples at 46–50 and 61–65 days are independent in that no female is represented in both samples.

Reproductive allocation can be sexually biased even with an unbiased sex ratio if investment is greater in individuals of one sex[21–23]. Although there is often marked variation in size among litter mates, we found no evidence of skewed somatic investment in individuals of either sex. Mean weights of male and female litter mates are statistically indistinguishable (Wilcoxon signed-rank test for paired observations, $P>0.2$ for controls and $P>0.5$ for provisioned females). Neither is there a sexual bias in mortality of pouch young examined between 15 and 45 days of age (Table 1) in either provisioned or control groups (G test, $P>0.8$ for both groups). Although maternal investment per individual is unbiased in both groups, provisioned females invest disproportionately in males by producing male-biased sex ratios. Controls, on the other hand, produce exactly as many male as female offspring (Fig. 2). The sex-ratio difference between groups is statistically significant: P (one-tail) = 0.007, binomial test. Overall, male-biased litters were produced by 55% of control females and 76% (13 of 17) of provisioned females with a sex-ratio bias.

The mechanism of this apparent sex-ratio manipulation is unknown. The sex ratios described above are those observed when pouch young were first old enough to be visually sexed. However, <2% of pouch young attached to teats died before the age at which they could be sexed, indicating that the sex ratios observed were essentially the same as those of initially attached young. Female opossums typically bear more young than can make their way to the pouch and find a functional teat[18], so it is possible that males of provisioned mothers are superior to females in their capacity to migrate successfully to the pouch. Alternatively, adult females might distinguish male from female young at birth and selectively remove females as they travel toward the pouch. Another possibility is that sex-ratio manipulation occurs before birth.

For this particular sex-ratio manipulation to be an adaptive response, the amount of maternal investment would have to have a larger effect on male than female reproductive success. One reason to suspect that this may be the case is the tendency for improvement in recapture rate of independent young from provisioned versus control females to be greater for males than females ($P=0.15$, binomial contrast; Table 1), suggesting that male survival is more affected by increased investment than is female survival. Other support for a greater effect on future male reproductive success derives from the putative relationship between adult body size and reproductive success. Among our control females, body size is uncorrelated with such fitness components as length of adult life ($r=0.088$, $t_9=0.250$, $P>0.5$),

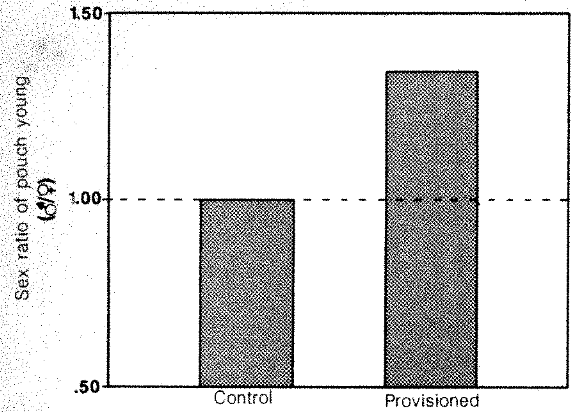

Fig. 2 Sex ratios of pouch young from control and provisioned females. Sex-ratio difference is significant (P(one-tail) = 0.007, binomial test). Control females, $n = 256$; provisioned females, $n = 270$.

litter size ($r = 0.135$, $t_{16} = 0.670$, $P > 0.5$), number of litters produced ($r = -0.065$, $t_9 = 0.195$, $P > 0.5$) or size of individual offspring ($r = -0.370$, $t_9 - 1.19$, $P > 0.25$). On the other hand, male body size could well be related to mating success. Male common opossums have large overlapping home ranges, so that each male has potential access to multiple females, but must contend with many other males who also have potential access[17]. Males fight vigorously in the presence of a receptive female, and a high proportion of all males captured during the breeding season show wounds consistent with male-male combat (our unpublished observations), whereas females do not exhibit such wounds. Male body size is known to be correlated with the ability to win contests in some mammals[24-26] including marsupials[27,28], and therefore plausibly correlates with access to mates.

Documentation of adaptive sex-ratio manipulation among mammals has remained elusive[2,6,8,29]. Part of the difficulty in observational studies could be in identifying key variables correlated with capacity for parental investment. For instance, the offspring sex ratio in red deer varies adaptively with maternal dominance rank[12], but does not vary with other plausible variables such as maternal age, home range size or parity[30]. Environmental variation could also obscure significant trends during any field study; for example, in a similar study of the Virginia opossum, food supplementation resulted in an overproduction of males during a year of normal rainfall, but failed to do so in a drought year (M.E.S., in preparation), possibly because even provisional females were not in exceptionally good condition during the drought. However it seems increasingly clear that taxonomically diverse mammal species can adjust their sex ratios as the theory predicts.

We thank Tomás Blohm for allowing us to work on his ranch and assisting us with logistical problems. We also thank Dennis Daneke and his assistants Brent Mitchell and David Manry for performing most of the fieldwork. We thank E. L. Charnov, T. H. Clutton-Brock, G. D. Dodson, J. F. Eisenberg, L. D. Marshall, J. Maynard Smith, W. R. Rice, M. J. A. Simpson and R. Thornhill for helpful comments on the manuscript. Supported by NSF grant BSR-8315125.

Wormy mice in a hybrid zone

Richard D. Sage*†, Donald Heyneman‡,
Kee-Chong Lim‡ & Allan C. Wilson*

* Department of Biochemistry and † Museum of Vertebrate Zoology,
University of California, Berkeley, California 94720, USA
‡ Department of Epidemiology and International Health,
University of California, San Francisco, California 94143, USA

As one approach to analysing the genetic barriers between species, we studied the numbers and types of parasitic worms in two species of house mice (*Mus musculus* and *M. domesticus*) and in their natural hybrids. Where the ranges of these two species meet in southern Germany, there is a zone of hybridization less than 20 kilometres across[1], in which about 98% of the mice have backcross genotypes. Fourteen of the 46 mice tested from within the zone have over 500 pinworms per gut, a number far exceeding the mean of 40 per gut for other mice inside and outside the zone. Other nematodes have a similar, non-random distribution. The number of mice bearing 9 or more tapeworms per gut is also excessive in the hybrid zone. These extraordinarily wormy mice may be unusually susceptible to parasitism; the different species may have different genes for resistance, and recombinant backcross animals may lose both[2]. Our findings support the view that the hybrid populations may have reduced fitness and thereby act as a genetic sink, interfering with the flow of genes between the two species[1,3]. The possibility that environmental or ecological peculiarities in the zone of hybridization make the mice more liable to infection is not supported.

Ninety-three mice, caught in barns and houses at 22 localities in southern Germany and adjacent Austria, were necropsied for worms in their tissues and intestinal tracts. These mice are part of a larger collection of about 300 individuals from 30 localities along a 200-km transect extending between Braunau and Augsburg. This transect encompasses the reported zone of hybridization between the eastern *M. musculus* and western *M. domesticus*[4,5]. A partial genetic characterization of mice from these 30 localities has appeared[1]. Animals were trapped alive during October 1984 (42 mice) and June 1985 (51 mice) and killed within 2 days of capture. All but 5 of the 93 mice were adults, weighing more than 12 g, and 40 were males. The carcasses were preserved in 10% neutral-buffered formalin for 1–2 months, soaked in water, and stored in 70% ethanol. The entire gastrointestinal tract was slit and examined, with associated organs, under a dissecting microscope.

The genotype of each mouse at four enzyme loci was determined by starch gel electrophoresis[1]. These two species have

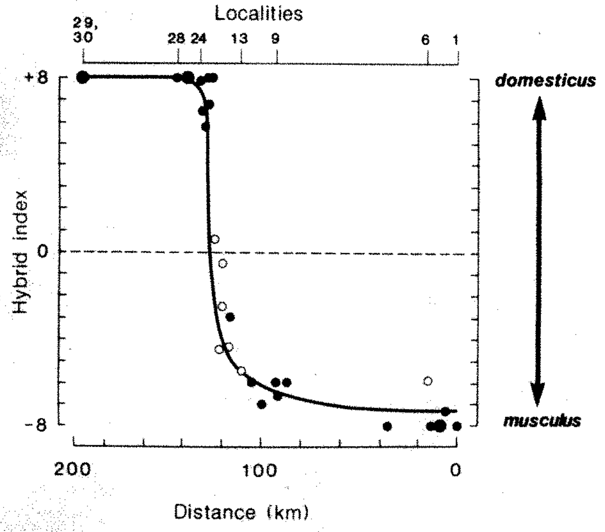

Fig. 1 Mean hybrid indices of 30 mouse populations based on electrophoresis of four diagnostic proteins. The samples come from localities 1–30 lying along a line extending between Braunau, Austria (1), and Augsburg, Germany (29, 30; ref. 1). Locality numbers of some of the 22 places from which mice were autopsied for parasites are indicated across the top; larger circles, two collections from the same city; ○, localities at which the 15 mice with excessive burdens of nematodes were found.

fixed allelic differences at loci for esterases 1 and 10, mannose phosphate isomerase-1 and nucleoside phosphorylase-1. A hybrid index (HI) based on the genotypes at these four loci was computed for 200 mice, including the 93 animals autopsied for parasites. As shown in Fig. 1, there is a nearly complete replacement of one species by the other across a distance of less than 20 km. The mitochondrial DNA, chromosomes, osteology, pelage coloration and hybrid sterility alleles also show this abrupt transition (R.D.S., unpublished).

Table 1 Numbers of worms per gut in 93 wild mice

Locality*	Hybrid index	No. mice	Mean abundance (maximum) Nematodes†	Cestodes‡
		Eastern region (*M. musculus*)		
1	−8	3	4.3 (10)	1.7 (3)

30	+8	3	54 (100)	0

* The locality numbers and the mean hybrid indices are given in ref. 1, Table 1.

† The five genera represented and total numbers of specimens found are: *Aspiculuris* (>5,740), *Syphacia* (>3,865), *Protospirura* (485), *Trichocephalus* (512) and *Trichuris* (65).

‡ The principal cestode genera (and the total numbers found) were *Hymenolepis* (97), *Catenotaenia* (64) and *Taenia* (14).

We found and identified more than 10,840 worms in the 93 mice. From Table 1, which gives the average number of worms per mouse at the 22 localities, it is evident that the highest worm burdens occur in the hybrid zone. Here, between localities 13 and 23, the average number of nematodes per mouse is greater than 197, the standard error being 32. By contrast, in the east the mean is 59 (±23) and in the west it is only 15 (±4). The caecal pinworms (*Aspiculuris* and *Syphacia*), which comprised 90% of the nematodes (Table 1), and other genera (*Protospirura*, *Trichocephalus* and *Trichuris*) also occurred in highest numbers in hybrid mice. A similar trend is apparent for cestode infections (Table 1): mice in the hybrid zone have an average of 3.2 (±0.97) worms, whereas the eastern and western mice have 0.9 (±0.23) and 0.6 (±0.13) respectively.

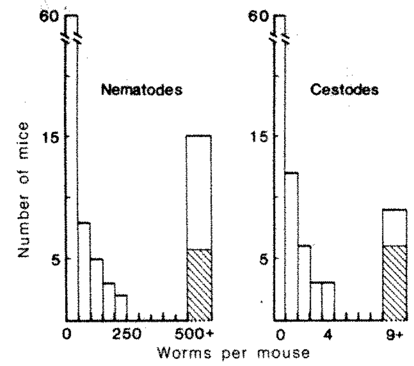

Fig. 2 The distribution of parasite burdens (number of worms per mouse) among 93 wild house mice captured at the 22 localities cited in Fig. 1: *a*, nematodes *b*, cestodes. Hatched columns, six mice that had excessive numbers of both nematodes (>500) and cestodes (>9).

The number of worms per mouse varies widely, from none to >620 (Table 1, Fig. 2). Table 2 shows that the distributions of worm burdens per mouse are highly skewed for each of the three regions, the variance exceeding the mean in nearly every case. Such skewed distributions are characteristic for parasites within their host populations[6,7]. The ratio of the variance to the mean is highest for the hybrid zone. This observation, in conjunction with the evidence shown in Fig. 3 and discussed below, may imply an association between worm numbers and particular genotypes.

We designate the 15 mice bearing >500 nematodes as 'wormy' and the remaining 78 mice (<250 nematodes) as 'normal' (most of the normal mice carry <50). The pattern of nematode burdens is associated with particular protein genotypes (Fig. 3). Fourteen of the 15 wormy mice have hybrid genotypes. Only one of these heavily parasitized mice has the genotype of a pure *M. musculus.* A χ^2 analysis of pure versus hybrid genotypes and wormy (>500 nematodes) versus normal (<250) mice gives a highly significant result ($\chi^2 = 9.6$, d.f. = 1, $P < 0.005$). Thus there are significantly fewer pure mice, and more hybrids than expected, that are heavily parasitized with nematodes.

Cestode infections show a similar pattern (Fig. 2*b*), although the maximum number of parasites per mouse is not as great as for nematodes. There are 84 normal animals with from zero to four cestodes, and nine wormy mice with heavy infections ranging from 9 to 30 worms. Eight of these wormy mice have hybrid genotypes (HI = −4 to +4), while one pure *domesticus* mouse had 11 cestodes. A χ^2 test of pure versus hybrid genotypes and

Table 2 Statistical analysis of worm numbers per mouse

Type of worm	Variance divided by the mean Eastern region ($n = 21$)	 Hybrid zone ($n = 46$)	 Western region ($n = 26$)
Nematodes			
Syphacia	263	368	50
Aspiculuris	51	343	30
Protospirura	3.9	84	1.0
Trichurids	9.1	160	18
Cestodes			
Hymenolepis	6.9	25	10
Other taenioids	1.5	12	0.8

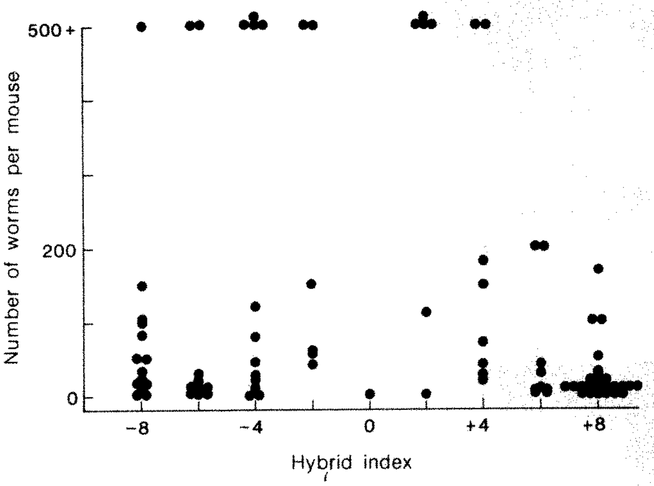

Fig. 3 Nematode burdens (number of worms per mouse) in relation to mouse genotype. The hybrid index is based on electrophoresis of four diagnostic proteins. Pure *M. musculus* has an index of −8; pure *M. domesticus* has an index of +8.

wormy (>8 cestodes) versus normal (<5) mice gives a significant result ($\chi^2 = 4.1$, d.f. $= 1$, $P < 0.05$). We infer that hybrid mice can be more heavily parasitized than genetically pure *M. musculus* or *M. domesticus*.

Excessive worminess seems not to be related to the sex of the mouse, as reported elsewhere[8]. Seven of the 15 mice with >500 nematodes, and three of the six animals most heavily infected with cestodes, were males. Also, the heavy infections are widely distributed within the hybrid zone and present during both collecting periods, suggesting that the causative agent does not come from some unique ecological or temporal factors in a particular mouse colony. No differences in habitat or mouse abundance were obvious between the collecting sites within the hybrid zone and in the adjacent regions. The 15 mice with the highest nematode burdens come from seven cities (Fig. 1), and the nine animals with heavy cestode infestations were collected at four locations (numbers 15, 18, 19 and 27).

Neither the high mean levels of nematodes in the hybrid zone ($\bar{x} = 198$) nor the extraordinarily high maximal counts (>500) found in some mice have been found in other sampled populations of wild *M. musculus*[9] or *M. domesticus*[10–14]. Although the pathological effects of these heavy worm burdens on wild mice have not been studied, laboratory experiments implicate pinworms in causing rectal prolapse, enteritis, liver granulomas and poor weight gains[15], as well as in altering immune responses to other disease agents[15]. Although the worm burdens are clearly not fatal to these wild mice, they seem likely to be deleterious.

The diversity of life cycles among these parasites is notable. The caecal pinworms and some of the intestinal *Hymenolepis* are transmitted directly from mouse to mouse but others have complex life cycles involving other animals as intermediate hosts. The epidemiological conditions needed to account for the worminess of these hybrids must therefore be diverse. The implication is that some of the mice are peculiarly susceptible to worm infections.

Because nearly all the wormy mice are hybrids, we suggest that the increased parasitism has a genetic basis. Reviews of the literature on resistance by small mammals to parasites[16–20] give many examples of genetically-based resistance to both uni- and multicellular parasites, including some of the helminths we found in the wild mice (*Aspiculuris*, *Hymenolepis*, *Trichuris*, and *Taenia*). The molecular and cellular mechanisms that mediate resistance to worms are diverse and are known to include immune-response and histocompatibility genes in mice[16,19,20]. It has been shown that the major genes for susceptibility to the bacterium *Salmonella typhimurium* reside on different chromosomes in *M. domesticus* and *M. musculus*[2], which implies different genetic mechanisms of resistance. Resistance to *Trichuris muris* and *Trichinella spiralis* behave as dominant characters. The reviews[16–20] emphasize the ubiquity and genetic simplicity of natural resistance.

These known cases of mouse resistance to parasites suggest that simple genetic models could explain our field observations. One possible model is that helminth resistance resides in different genes in *M. musculus* and *M. domesticus*, and that wormy mice have recombinant genotypes. If the resistance genes are dominant in the wild, as in the laboratory, then the susceptible, wormy mice would arise after the initial hybridization events, from a mating between recombinant animals. Alternatively, resistance could be conferred by a combination of alleles at two linked loci and the alleles conferring resistance could differ in the two species. Recombination would break up advantageous combinations of alleles. Parental and F_1 genotypes are rare in the hybrid zone; nearly all the mice have backcross genotypes[1]. Thus, these hybrid populations have genetic constitutions compatible with either of these genetic models.

The initial field observation (R.D.S.) which led to this quantitative analysis of helminth parasitism was the apparently greater numbers of fleas on the recently killed, hybrid mice, in comparison to non-hybrids. Conversations with colleagues who study hybridization in other species indicate that hybrids may frequently have more parasites than the adjacent parental populations (for example, gall aphids on cottonwoods, gill parasites in stone crabs, and intestinal worms in two genera of salamanders; T. Bert, T. Kocher, S. Sessions and T. Whitham, personal communication). If future studies verify higher-than-normal levels of parasitism and 'disease' in other hybrid zones, they would encourage the view that the loci which change fastest in response to selection after two populations separate are often those controlling resistance to parasites[21].

We thank I. Butler, K. Damme, J. Klein, R. Kraft, F. Seidl, H. Tichy, F. Pirchner and the people who allowed us to trap mice in their buildings, P. Bateson, W. Hamilton, F. James, A. Kuris, E. Mayr, E. Prager, J. Shields and S. Sweet for discussion about the manuscript, and the NSF for financial support.

The extensive range of specificities of T-cell receptors is generated, as for immunoglobulins, by rearrangement of genetic information[1]. Much valuable information about rearrangement processes has been inferred by comparing DNA from (monoclonal) lymphoid lines with germ-line DNA[2,3] and, for B cells, from rearrangements in some Abelson murine leukaemia virus-transformed cell lines[4,5]. However, because it is difficult to isolate and grow precursor populations, it has not proved possible to study rearrangements occurring in normal untransformed cells *in vitro*. Here we show that a single T-cell precursor colonizing an alymphoid thymus lobe in organ culture can generate multiple receptor β-chain gene rearrangements. These observations provide unequivocal evidence for the intra-thymic diversification of the T-cell repertoire. They also offer the possibility of investigating rearrangement and its control in the clonal progeny of a single normal T-cell precursor without the perturbations involved in the use of viral transformation or the production of T-cell hybridomas.

T cells require both specific antigen and self major histocompatibility (MHC) determinants[6,7] for activation. They possess a cell surface receptor made up of α- and β-chains[8,9] encoded by genes which are rearranged and expressed only in T lymphocytes[10,11]. The rearrangement of receptor β-chain genes during mouse fetal development has been monitored by hybridizing β-chain gene probes to restriction enzyme-digested DNA from cells at different stages of development[12,13]. The proportion of thymic lymphocytes showing rearrangement of the β-chain genes is very small at day 14, then increases progressively. Several interpretations of these observations are possible: (1) gene rearrangement may occur in the thymus; (2) rearranged populations may proliferate preferentially in the thymus; (3) there may be progressive recruitment of rearranged cells into the thymus; or some combination of these processes. To distinguish between these possibilities we used a recently developed technique[14] to recolonize an alymphoid thymic lobe with a single blast cell derived from 14-day fetal thymus. Successfully recolonized lobes yield up to 1.1×10^5 lymphocytes, and contain various T-cell marker defined sub-populations, all derived from the single donor cell[14]. If rearrangement had already occurred at the 14-day stage, either within the thymus or at a pre-thymic level, one or two rearranged bands would be detected. If no rearrangement had occurred by the 14-day stage or during organ culture a strong germ-line pattern would still be evident, while

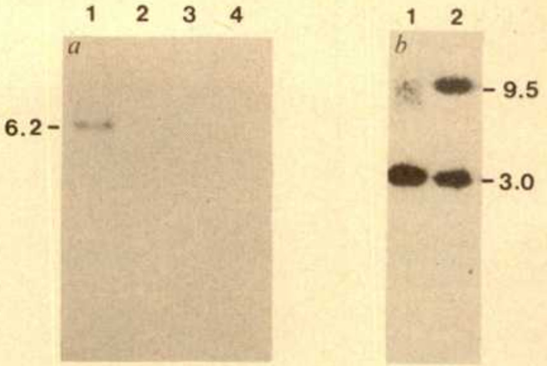

Fig. 1 Southern blot analyses of T-cell receptor β-chain genes in the populations produced in thymus lobes recolonized by a single T-cell precursor. *a*, *Pvu*II digestion of: lane 1, liver DNA; lanes 2-4, progeny of single cells; *b*, *Hin*dIII digestion of: lane 1, progeny of single cell; lane 2, liver DNA. Alymphoid CBA (H-2^k) thymus lobes were prepared and each was recolonized by a single T-cell precursor taken from a 14 day of gestation BALB/c thymus lobe as described previously[14]. *a*, DNA was prepared from the lymphoid cells produced from single precursors, digested with *Pvu*II, separated on an agarose gel, Southern blotted and hybridized with a ^{32}P-labelled probe for the constant region of the β-chain gene. Filters were washed at high stringency before autoradiography. Liver DNA (β-chain gene complex in germ-line state) was analysed in parallel. The two constant region genes are not resolved and migrate with an apparent size of 6.2 kb (liver DNA, lane 1). The substantial reduction in these bands in the progeny of single cells, with no dominant rearranged band, indicates that multiple rearrangements have occurred (lanes 2-4). Five other lobes analysed all showed similar results (data not shown). The filter was rehybridized with a probe for β_2-microglobulin, confirming that about the same amount of DNA was present in all tracks. *b*, DNA from the progeny of a single cell (lane 1) and liver DNA (lane 2) were digested with *Hin*dIII and analysed as above. In the germ-line state (lane 2) the $C_\beta 1$ restriction fragment migrates with an apparent size of 9.5 kb, and the $C_\beta 2$ fragment with an apparent size of 3.0 kb. In the DNA from the single cell progeny the germ-line $C_\beta 1$ fragment has been sharply reduced and a smear of bands has appeared. This indicates that heterogeneous multiple rearrangements have occurred within the thymus.

Methods. Alymphoid lobes were obtained after culture in the presence of deoxyguanosine (dGuo) and associated with single micromanipulated precursors for 24 h in hanging drops formed in Terasaki plates, with subsequent transfer to organ culture for 11-13 days for optimal expansion of successfully recolonized lobes. This produces lobes exclusively recolonized by progeny of the single donor precursor[14]. At the end of the organ culture period lymphoid cells were released from individual thymus lobes by gentle teasing with fine cataract knives and the resultant suspension was washed in Tris-buffered Earles saline and frozen at −80 °C before preparation of DNA. For *Pvu*II digestion DNA was prepared by proteinase K digestion in 0.5% SDS followed by phenol-chloroform extraction and extensive dialysis. After *Pvu*II digestion to completion, the DNA was precipitated with ethanol and separated by electrophoresis on a 0.8% agarose gel. For *Hin*dIII digestion the frozen cell pellet was digested with proteinase K in 0.5% sodium lauroyl sarkosinate and 1% low gelation temperature agarose (Bio-Rad). The agarose was allowed to solidify at 0 °C and detergent was removed by incubation with several changes of 10 mM Tris 1 mM EDTA *p*H 8.0 (G.T.W., manuscript in preparation). The DNA was digested with *Hin*dIII in the presence of 0.1% nuclease-free bovine serum albumin and separated on a 0.6% agarose gel (normal gelation temperature). Gels were blotted onto Zeta-probe (Bio-Rad) membranes and hybridized with an oligo-labelled[19] C_β probe derived from plasmid 86T1[11]. Filters were washed at high stringency and autoradiographed for 10 days using Kodak XAR-5 film and two intensifying screens (Dupont Cronex Lightning-plus).

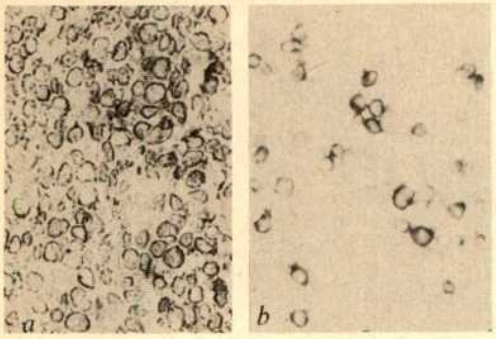

Fig. 2 Detection of T-cell receptor β-chain expression in the progeny of a single T-cell precursor. *a*, Labelling with anti-Lyt 2.2; *b*, labelling with F-23.1, a monoclonal antibody that recognizes the products of a V_β gene family present on approximately 25% of peripheral T cells[15]. Alymphoid CBA (H-2^k, Lyt 2.1) thymus lobes were recolonized by a single BALB/c (H-2^d, Lyt 2.2) precursor (Fig. 1 legend). After 11–13 days of organ culture individual lobes were snap frozen and four frozen sections prepared for indirect immunoperoxidase labelling. Two sections taken from the same lobe are shown. *a*, Labelling with monoclonal anti-Lyt 2.2 (NEN); most lymphoid cells are labelled, indicating that they have undergone differentiation in terms of T-cell marker expression and that they are derived from the single BALB/c (Lyt 2.2) precursor; as shown in our previous work, dGuo-treated lobes recolonized by a single cell contain T cells exclusively of donor type[13,20]. *b*, The labelling with F-23.1 demonstrates productive rearrangement in a proportion of cells, but does not provide a quantitative estimate of the extent of T-cell receptor β-chain diversity, as the proportion of receptor-positive cells is unknown. However, the observed proportion of F-23.1^+ cells is fully consistent with the heterogeneous multiple β-chain gene rearrangements shown in Fig. 1. The large reduction in the C_β germ-line bands shown in Fig. 1 suggests that most of the F-23.1^- cells have also rearranged the β-chain gene locus, although not all of these rearrangements may be productive and a proportion of cells may not synthesize any β-chain. The F-23.1 labelling might detect surface and/or cytoplasmic β-chain expression[21] (in a recent study using a double immunofluorescence procedure we have found that, in newborn thymus, approximately equal proportions of cytoplasmic F-23.1^+ and surface F-23.1^+ cells are present[22]). As further proof that the progeny of a single cell can proceed to productive receptor expression, alymphoid CBA lobes (Thy 1.2) were recolonized by single AKR (Thy 1.1) precursors. Double immunofluorescence labelling with anti-Thy-1.1 and F-23.1 showed that 90% of cells were Thy-1.1^+ and 3.3% of these were surface F-23.1^+, a value similar to that observed in non-manipulated thymus organ cultures[13].

multiple rearrangements in the progeny of the single cell in the organ-cultured thymus would reduce the germ-line bands without producing any dominant rearranged bands.

The lymphocyte DNA from several lobes, each recolonized by a single cell, was prepared and analysed separately by restriction digestion, gel electrophoresis, Southern blotting and hybridization with radiolabelled β-chain constant region probes (Fig. 1). For *Pvu*II-digested DNA the intensity of the 6.2-kilobase (kb) band corresponding to the germ-line ($C_\beta1$ and $C_\beta2$) genes decreased markedly in lymphocytes from recolonized lobes, indicating extensive multiple rearrangements (Fig. 1*a*). In *Hin*dIII-digested liver DNA a 9.5-kb band corresponds to $C_\beta1$ and a 3.0-kb band to $C_\beta2$. Rearrangement to either β-chain constant region reduces the intensity of the 9.5-kb band through deletion or rearrangement of $C_\beta1$, but does not affect the 3.0-kb fragment, which thus acts as an internal marker[11,12]. The 9.5-kb ($C_\beta1$) band is sharply reduced in the DNA of the progeny of the single precursor showing that the cells have undergone multiple β-chain gene rearrangements (Fig. 1*b*). The heterogeneity of the rearrangements in the lymphoid cells is confirmed by the appearance of a smear of rearranged bands. All nine lobes analysed showed multiple rearrangements.

To demonstrate productive β-chain gene rearrangements from a single thymic stem cell we used a monoclonal antibody (F-23.1), which reacts with a sub-population of β-chain variable regions[15] to look for expression of β-chain. A significant proportion of the cells produced from single precursors express T-cell receptor β-chains (Fig. 2), so many of the gene rearrangements detected are indeed productive.

The recolonization of alymphoid thymic lobes by single micromanipulated precursors has allowed us to provide a definitive demonstration of gene rearrangement involved in the generation of T-cell receptor β-chain diversity in the thymus. Neither progressive recruitment nor preferential proliferation of cells with rearranged β-chain genes could account for these observations as neither is possible in this system. This is the first *in vitro* demonstration of generation of diversity in any receptor molecule of the immune system from a single untransformed cell. Since these results show that the thymic environment is sufficient to induce β-chain gene rearrangements in T-cell precursors, they argue against the need for pre-thymic rearrangement as suggested by some functional studies[16,17]. Furthermore, 14-day thymus cells, although capable of proliferation *in vitro*, do not undergo rearrangement outside the thymus[18]. Thus the thymic environment is important in initiating the rearrangement process. This system provides a method for investigating intercellular interactions in the thymus, as well as the molecular mechanisms which produce gene rearrangements during T-cell differentiation. The technique should also prove invaluable in identifying pre-thymic T-cell precursors in normal and transformed populations by their capacity to undergo receptor gene rearrangement when introduced into a thymus. The pattern of rearrangement and β-chain utilization obtained when progressively more mature cells are re-introduced into the thymus may also be analysed using this approach.

This work was supported by the MRC (E.J.J., R.K. and J.J.T.O.), the Rowbotham Bequest (G.T.W., E.J.J) and Wellcome Trust (G.T.W.). We thank Dr M. M. Davies for clone 86T1, Dr M. Bevan for monoclonal antibody F23.1, Dr K. Docherty, Mr I. Phillips and Dr F. H. C. Franklin for help and advice, Alison Orchard for assistance with the photography and Claire Hundley for typing the manuscript.

Extensive proliferation of mature connective-tissue type mast cells *in vitro*

Tatsutoshi Nakahata*, Toshimi Kobayashi*, Akira Ishiguro*, Kohichiro Tsuji*, Kuniaki Naganuma*, Osaaki Ando*, Yoshio Yagi*, Kenji Tadokoro† & Taro Akabane*

* Department of Pediatrics, Shinshu University School of Medicine, Asahi 3-1-1, Matsumoto 390, Japan
† Department of Medicine and Physical Therapy, University of Tokyo, Tokyo 113, Japan

There are two phenotypically distinct subpopulations of mast cells in rodents: connective tissue-type mast cells (CTMC) and mucosal mast cells (MMC). These populations differ in their location, cell size, staining characteristics, ultrastructure, mediator content and T-cell dependency[1–3]. Several investigators[4–9] recently reported a further subclass of mast cells which arise when normal mouse haematopoietic cells are cultured with interleukin-3 (IL-3); IL-3 is an activity similar or identical to mast-cell growth factor, histamine-producing factor, or P-cell stimulating factor[4–9]. These cultured mast cells are in many ways similar to MMC; they stain with Alcian blue but not safranin, contain chondroitin sulphate E proteoglycan rather than heparin proteoglycan and have relatively low histamine content, as do MMC[10–13]. Although proliferation of MMC is known to be T-cell dependent *in vivo* and thought to be IL-3-dependent *in vitro*, the factors on which CTMC proliferation depends remain elusive. Here we show that mature CTMC purified from mouse peritoneal cells can proliferate *in vitro* in methylcellulose culture and maintain the appearance and function of CTMC. We also present evidence that mature CTMC cannot proliferate in the presence of pure IL-3 alone.

When normal mouse peritoneal cells were cultured in methylcellulose medium containing pokeweed mitogen-stimulated spleen-cell-conditioned medium (PWMSCM), pure mast-cell colonies developed[14]. Detailed histochemical analyses of individual mast-cell colonies, together with observations of colony shape and size, allowed us to classify them into two types, type 1 and type 2 (Fig. 1*a*,*d*). The primary difference between colony types 1 and 2 was size: type 1 were smaller and more compact and revealed no signs of degeneration over 30 days of cultivation without additional feeding. Type 1 colonies contained 20 to 500 large mast cells with a single nucleus and many large granules (Fig. 1*b*); type 2 usually contained >2,000 small mast cells, with relatively small granules on day 16 of cultivation (Fig. 1*e*) and occasionally bilobed nuclei.

The two types of colonies could be more clearly distinguished by staining with Alcian blue–safranin or Berberine sulphate, or by measuring cellular histamine content. Cytocentrifuge preparations stained with Alcian blue–safranin and Berberine sulphate showed that most of the type 1 mast cells were both safranin-positive and Berbine sulphate-positive, whereas most of the type 2 mast cells stained with Alcian blue but not with safranin or Berberine sulphate (Table 1). Berberine sulphate staining has been reported to be highly specific for connective tissue-type mast cells, which contain heparin[15,16]. We confirmed this by demonstrating that the staining was blocked by treating the cells with heparinase but not chondroitinase ABC. The histamine content of type 1 cells was significantly greater than that of type 2 cells (Table 1). These data strongly suggest that most type 1 cells are CTMC-like[1–3,17]; by contrast, the type 2 cells resemble bone marrow-derived cultured mast cells, which have some characteristics in common with MMC[3,10,11,17].

We separated the precursors of type 1 mast-cell colonies from those of type 2 mast-cell colonies by removal of phagocytes followed by density gradient centrifugation (Table 2). Both types of precursor was enriched by the removal of phagocytes. Eight fractions were separated by Percoll density-gradient

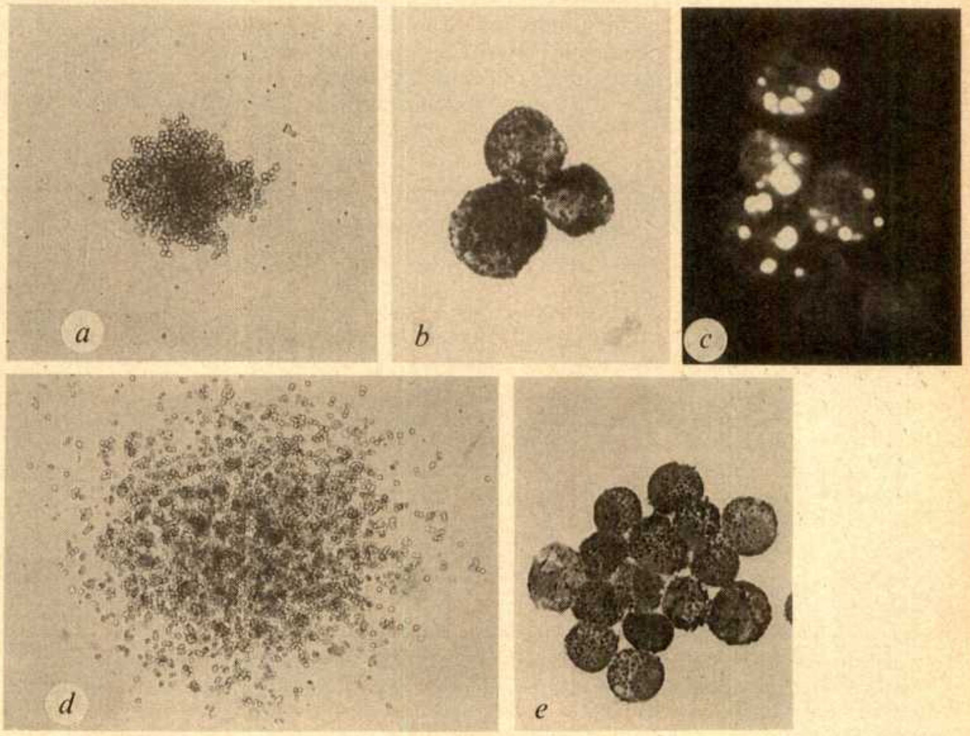

Fig. 1 Mast-cell colonies. *a*, Typical type 1 mast-cell colony on day 16 of culture; *b*, May-Grunwald–Giemsa-stained smear on the type 1 mast-cell colony shown in *a*; *c*, Berberine sulphate staining of the same colony; most mast cells show fluorescence; *d*, typical type 2 mast-cell colony on day 16 of culture; *e*, May-Grunwald–Giemsa-stained smear of the type 2 mast-cell colony shown in *d*.

Methods. Peritoneal cells from 20–25-week-old BDF$_1$ mice were collected as described previously[14]. Methylcellulose cultures were carried out by using a modification of the technique described previously[14,29]. Culture mixture (1 ml) containing 1×10^5 peritoneal cells, α-medium (Flow), 0.8% methylcellulose (Shinetsu Kagaku Co), 30% fetal bovine serum (Flow), 1% deionized bovine serum albumin (Sigma), 10^{-4} M mercaptoethanol (Eastman) and serum-free PWMSCM was incubated at 37 °C in a humidified atmosphere flushed with 5% CO_2 in air. Serum-free PWMSCM was prepared as described previously[30]. Mast-cell colonies containing ≥20 cells were counted on day 16. Individual colonies were lifted from methylcellulose medium using 3 μl Eppendorf pipette under a microscope and collected in Eppendorf microcentrifuge tubes containing 0.5 ml phosphate-buffered saline. After washing, the samples were spun in a cytocentrifuge (Shandon) (800 r.p.m. for 5 min) and stained with May-Grunwald–Giemsa, Alcian blue–safranin[31] or Berberine sulphate[16].

Table 1 Differences between types 1 and 2 mast-cell colonies

Type of mast-cell colony	No. of cells per colony	Cell size	Positive cells stained with Berberine sulphate	Alcian blue	Safranin	Histamine content (ng per 10^5 cells)
1	258 ± 35*	18.9 ± 1.9 μm	65.1 ± 21.2	77.4 ± 8.8	98.8 ± 0.9	64.74
	(20–500)†	(15–23)*	(18–98)	(55–87)	(94–100)	
2	8,500 ± 558	13.3 ± 3.7	0	100	1.4 ± 0.4	5.88
	(2,000–18,500)	(7–21)			(0–5)	

Colony size was determined by direct cell counting *in situ* with ×200 magnification on an inverted microscope when colonies consisted of less than 500 cells. When colonies contained >500 cells, a counting chamber was used. We analysed 50 types 1 and 2 mast-cell colonies. The histamine content was assayed using pooled colonies.

* Mean ± s.d.; † range.

centrifugation and individual fractions were analysed for cellular composition and relative concentration of the two types of precursor. The proportion of morphologically identifiable mast cells was increased in the heavier fractions and roughly paralleled the number of type 1 colonies. For example, fraction 7 (≥ 1.13 g ml^{-1}) was an almost pure population of large mast cells all of which stained with both safranin and Berberine sulphate but not with Alcian blue, and were thus classed as mature CTMC[18]. When these cells were cultured in methylcellulose medium containing PWMSCM approximately half the cells gave type 1 colonies, but no type 2 colonies developed (experiment 2, Table 2). It is of interest that, although these colonies contained mostly safranin-positive, Berberine sulphate-positive cells, about half the colonies contained small numbers of Alcian blue-positive, safranin-negative cells which are thought to be a more primitive stage than CTMC[18]. The clonal origin of type 1 colonies was confirmed using single-cell culture[19]. Cells in fraction 7 were plated at a concentration of 1×10^3 per ml in methylcellulose medium containing PWMSCM in 35-mm plastic dishes. A single mast cell was identified morphologically, lifted from the medium using a fine Pasteur pipette attached to a Leitz micromanipulator, transferred to a fresh culture dish and incubated for 16 days. Fifteen of 50 transferred single mast cells produced colonies, all of which were type 1. Thus some morphologically identifiable mature CTMC can proliferate *in vitro* to give colonies containing cells with CTMC-like features in the absence of accessory cells. This conclusion is supported in part by recent *in vivo* studies indicating that some peritoneal mast cells retain extensive proliferative potential after injection into the skin of mast-cell-deficient mice[20].

Sequential replating experiments of individual type 1 colonies derived from the cells in fraction 7 confirmed the proliferation potential of mature CTMC. Most of the primary colonies produced many secondary and tertiary colonies in methylcellulose medium containing PWMSCM. Although all the primary colonies contained mostly Berberine sulphate-positive, safranin-positive cells, there was a gradual decrease in the incidence of Berberine sulphate-positive mast cells and an increase in that of Alcian blue-positive, safranin-negative mast cells in individual secondary and tertiary colonies (data not shown). These findings suggest that some mature CTMC may be able to 'regress' and become a more immature type of CTMC or acquire some of the features of MMC. It will be necessary to perform a detailed biochemical examination of individual colonies to confirm this possibility.

Cells in fraction 2 (≤ 1.05 g ml^{-1}; lymphocytes, lymphoblastoid cells and no detectable mast cells) produced only type 2 mast-cell colonies, consisting of Alcian blue-positive cells which did not stain with either safranin or Berberine sulphate (Table 2). The number of type 2 mast-cell colonies that developed was linearly related to the number of cells plated (data not shown), suggesting that the colonies were of clonal origin. Type 2 precursors of mast-cell colonies have a similar (low) density to bone marrow precursors of factor-dependent cultured mast cells[21].

Table 2 Cellular composition and concentration of mast-cell precursors in fractionated peritoneal cells

Experiment	Origin of cells	Cellular composition: Mast cells	Lymphoid cells	Number of colonies per 10^5 cells: Type 1 mast cell colony	Type 2 mast cell colony	Total plating efficiency
1	Unseparated cells	0.9%	53.9%	102 ± 25*	2 ± 1	0.1%
	Nonphagocytic cells	1.6	98.1	308 ± 15	4 ± 1	0.3
	Fraction 2	0	100	0	22 ± 2	0.02
	3	0	100	0	7 ± 2	0.01
	4	1.8	98.2	321 ± 28	3 ± 1	0.3
	5	97.9	2.1	8,230 ± 151	0	8.2
	6	100	0	19,930 ± 505	0	19.9
	7	100	0	16,210 ± 309	0	16.2
2	Fraction 2	0	100	0	12 ± 1	0.01
	7	100	0	50,608 ± 2,131	0	50.6

Phagocytic cells were removed using carbonyl iron[32]. Percoll (Pharmacia) was made isosmotic by the addition of 1 part of 10× Hanks' solution containing 1% bovine serum albumin and 200 mM HEPES to 9 parts of Percoll. Continuous density gradients of Percoll were generated by centrifugation of 7 ml of Percoll solution at 23,000g for 60 min at 4 °C in a Tomy RS-20 FIIIS fixed rotor. Cell suspension (1 ml) containing 1×10^7 nonphagocytic cells was layered on the top of Percoll continuous gradients and centrifuged at 500g for 30 min[20]. Although eight fractions were separated, fractions 1 and 8 were discarded because the former contained degenerated cells and the latter contained a small number of macrophages which phagocytosed iron particles. Cellular composition was determined on cytocentrifuge preparations stained with May-Grunwald-Giemsa. Each fraction was cultured before (Fig. 1 legend).

* Mean ± s.d. of triplicated cultures.

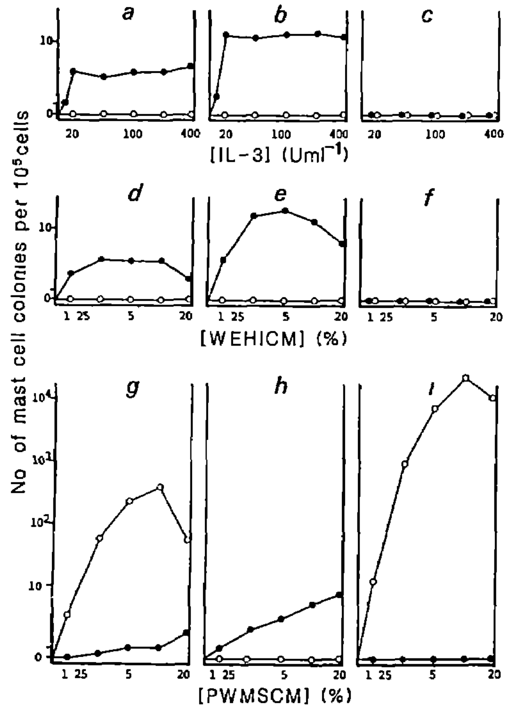

Fig. 2 Dependence of colony growth on growth factors Growth of colony types 1 and 2 from *a*, *d*, *g*, unseparated peritoneal cells, *b*, *e*, *h*, cells in fraction 2, *c*, *f*, *i*, cells in fraction 7 at varying concentrations of *a*–*c*, pure IL-3 in culture, *d*–*f*, WEHICM, and *g*–*i*, PWMSCM Open circles, type 1 mast-cell colony, filled circles, type 2 colony

Thus the precursors for two distinct types of mast cell can be separated by Percoll density-gradient centrifugation

We investigated the growth factor requirements of the two types of mast-cell precursors Homogeneous populations of mast cells resembling MMC are obtained *in vitro* from mouse bone marrow, spleen, fetal liver and lymphoid tissue in cultures supplemented with conditioned medium from stimulated T cells or the WEHI-3B cell line[4-7] It has been demonstrated that the biologically active component in the conditioned medium is IL-3[8,9,12,22] However, little is known about the factor(s) supporting CTMC proliferation *in vitro* Complex culture systems have been reported in which heparin-containing mast cells differentiate when the culture contains embryonic fibroblasts and lymphocytes from mice preimmunized to horse serum[23] Recent observations show that rat CTMC can be maintained *in vitro* in the presence of living fibroblasts but do not divide, and that fibroblast-derived conditioned medium does not have any ability to maintain CTMC[24] We next examined whether conditioned media (other than PWMSCM) or pure IL-3 support the proliferation of either type 1 or type 2 colonies in our methylcellulose culture system Neither type of colony will grow in the presence of lung-conditioned medium (containing granulocyte-macrophage colony stimulating factor and granulocyte-colony stimulating factor[25,26]) L-cell conditioned medium (containing macrophage colony stimulating factor[27]) also failed to stimulate colony growth

Figure 2 shows the plating efficiencies of two types of mast-cell colonies from unfractionated or fractionated peritoneal cells stimulated by different concentrations of pure IL-3, WEHI-3B conditioned medium (WEHICM) or PWMSCM No type 1 mast-cell colonies were observed in the presence of up to 400 U ml^{-1} of pure IL-3 in the culture WEHICM also failed to stimulate type 1 mast-cell colony growth PWMSCM stimulated type 1 mast-cell colony growth from unfractionated cells and fraction 7 significantly at a maximum concentration of 10% Pure IL-3 produced type 2 mast-cell colonies from unfractionated cells and fraction 2 in a dose-dependent fashion, reaching a plateau at 20 U ml^{-1} IL-3 Pure IL-3 also supported the growth of secondary mast-cell colonies consisting of cells which stained with Alcian blue but not with safranin or Berberine sulphate upon replating of type 2 colonies Our experiments show that the two types of mast-cell precursors are different in origin and in requirement for growth factors The IL-3 dependent growth of the low density precursors for type 2 colonies is consistent with a previous report that bone marrow precursors are distinct from mast cells, have a low density and proliferate in response to IL-3[21] Our PWMSCM contained some factor(s) that stimulate mature CTMC proliferation and is not IL-3 However, our data do not exclude the possibility that IL-3 can act as a co-stimulator for CTMC proliferation, because there was a small amount of IL-3 in the cultures containing 10% (v/v) PWMSCM (3 6 U ml^{-1} 100 U activity was arbitrarily defined as that amount of IL-3 per ml that gives 30% of maximal ^{3}H-thymidine incorporation into the IL-3 dependent cell line 32 Dcl[28]) Further studies are needed to determine the nature and source of the factor(s) responsible for mature CTMC proliferation

The CTMC culture system described here should allow the elucidation of the cellular and molecular mechanisms that control the proliferation of mature CTMC An examination of the changes in phenotype and processes involved in turnover of mediators during extensive proliferation should also be possible

We thank Drs Y Kitamura and A Komiyama for helpful advice and Dr J N Ihle for pure IL-3 Supported by grants from the Ministry of Education, Science and Culture, Japan

A chimaeric receptor allows insulin to stimulate tyrosine kinase activity of epidermal growth factor receptor

Heimo Riedel, Thomas J. Dull, Joseph Schlessinger* & Axel Ullrich

Department of Developmental Biology, Genentech, Inc ,

California 94080, USA

The cell surface receptors for insulin and epidermal growth factor (EGF) appear to share a common evolutionary origin, as suggested by structural similarity of cysteine-rich regions in their extracellular domains and a highly conserved tyrosine-specific protein kinase domain[1-3]. Only minor similarity is found outside this catalytic domain, as expected for receptors that have different ligand specificities and generate different biological signals[4,5]. The EGF receptor is a single polypeptide chain[6] but the insulin receptor consists of distinct α and β subunits[7] that function as an $\alpha_2\beta_2$ heterotetrameric receptor complex[8-11]. Provoked by this major structural difference in two receptors that carry out parallel functions, we have designed a chimaeric receptor molecule comprising the extracellular portion of the insulin receptor joined to the transmembrane and intracellular domains of the EGF receptor to investigate whether one ligand will activate the tyrosine kinase domain of the receptor for the other ligand. We show here that the EGF receptor kinase domain of the chimaeric protein, expressed transiently in simian cells, is activated by insulin binding. This strongly suggests that insulin and EGF receptors employ closely related or identical mechanisms for signal transduction across the plasma membrane.

Cloned human EGF receptor[1] and insulin receptor complementary DNAs[2,3] were used in combination with simian virus 40 (SV40) early promoter transcriptional elements (Fig 1*a*) to generate expression constructs coding for the complete human insulin receptor (HIR) and a chimaeric receptor (IER), shown in Fig 1*b* The insulin receptor is normally made as a precursor and proteolytically processed to generate the α and β subunits[4] IER was generated by fusing the coding region of the signal sequence and extracellular portion of the insulin receptor precursor (amino acids −27–914) to the coding sequence of the transmembrane and cytoplasmic domains of the EGF receptor[1] (amino acids 622–1,186) Using this chimaeric construct we asked whether the hybrid receptor would be proteolytically processed into insulin receptor α subunit and the recombinant IβE subunit, whether a functional complex would be formed and directed to the plasma membrane and whether insulin binding could stimulate autophosphorylation of the EGF receptor cytoplasmic domain in the chimaeric cell surface membrane glycoprotein

Expression of the complete insulin receptor resulted in protein products of relative molecular mass (M_r) 95,000 (95 K) and 180 K and a diffuse band around 135 K, as determined by ^{35}S-methionine metabolic labelling (Fig 2*a*) These polypeptides represent the β-subunit, the uncleaved precursor and the glycosylated α subunit of the insulin receptor[2,9,12-14] Proteolytic processing of the native insulin receptor precursor is inefficient under transient expression conditions in COS-7 cells, as one can see from the amount of HIR precursor remaining

By analogy with the native receptors, COS-7 cells expressing the IER receptor chimaera would be expected to synthesize a 135 K glycosylated α-chain, a comparably sized 120 K glycopolypeptide composed of the intracellular and transmem-

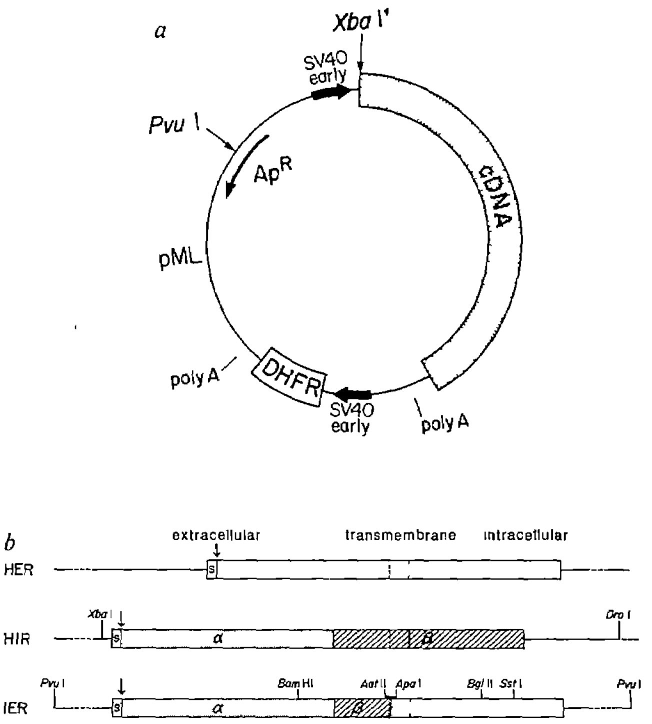

Fig. 1 *a*, Receptor expression plasmid, *b*, schematic comparison of normal and chimaeric receptor constructs *a*, The region encoding different receptor constructs is shaded (cDNA) Early SV40 promoter sequences are shown by heavy black arrows and poly-(A) addition sites are indicated The dihydrofolate reductase (DHFR) coding sequence[19] and restriction sites used for plasmid constructions are shown Expression of both cDNAs was controlled by promoter sequences of the SV 40 early region Sequences of the *Escherischia coli* plasmid pML (ref 20) were present to allow plasmid replication in *E coli* *b*, Coding regions of human EGF receptor (HER), human insulin receptor (HIR) and insulin-EGF receptor chimaera (IER) Shaded regions, HIRα subunit sequences, striped regions, HIRβ sequences, unshaded regions, HER sequences The sequences are aligned at their transmembrane domains (not to scale) S, signal sequences, arrows, signal sequence cleavage sites, vertical lines, receptor precursor cleavage sites, zigzag line, junction between heterologous receptor cDNAs, black bar, synthetic oligonucleotide used for the connection

Methods. Construction of the HIR expression plasmid a *Sal*I restriction fragment containing the entire HIR protein coding sequence[2] was introduced into the *Sal*I site in the polylinker region of the plasmid pUC12 DNA was amplified and molecules containing the 5′ end of the HIR coding sequence next to the pUC12 *Xba*I site were used to generate a *Xba*I-*Dra*I restriction fragment containing the complete HIR protein coding sequence This fragment was introduced into the mammalian expression vector (Fig 1*a*) at an *Xba*I and a filled-in *Bam*HI site in the orientation *Xba*I/*Xba*I-*Dra*I/*Bam*HI Construction of the IER expression plasmid a 931 bp *Bam*HI-*Aat*II restriction fragment from the HIR expression plasmid and a 1,150 bp *Apa*I-*Sst*I restriction fragment of the human EGF receptor sequence[1] were joined at their respective *Aat*II and *Apa*I sites with the complementary synthetic oligonucleotides 5′-CCCGTCAAATATCGCCACTGGGATGG-TGGGGGCC-3′ and 5′-CCCACCATCCCAGTGGCGATATTT-GACGGGACGT-3′ The ligated fragments were inserted into a *Sst*I/*Bam*HI digested pUC12 vector, giving a combination of the sequences coding for the extracellular domain of the insulin receptor with the transmembrane and cytoplasmic domains of the EGF receptor A 965 bp *Bam*HI-*Apa*I fragment of this plasmid, containing the IER junction, was then ligated to a 3 1 kb *Pvu*I-*Bam*HI fragment of the HIR expression plasmid, which contained the rest of the HIR coding sequence and parts of the expression vector, and to two fragments (810 bp *Apa*I-*Bgl*II and 5 3 kb *Bgl*II-*Pvu*I) coding for the transmembrane and cytoplasmic domains of the human EGF receptor, with the latter also containing sequences of the expression vector

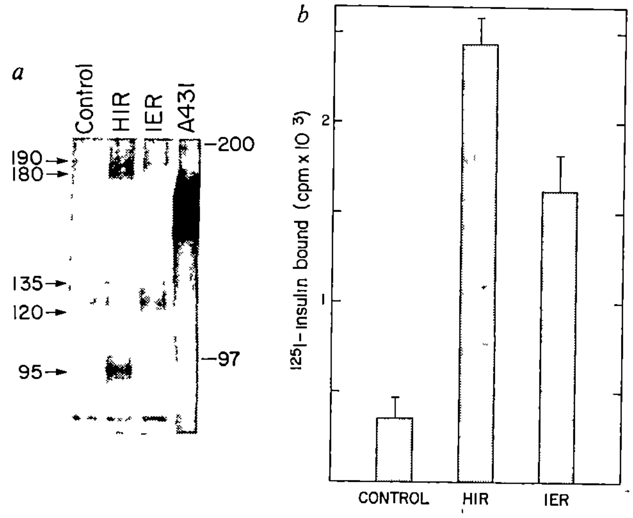

Fig. 2 a, ^{35}S-methionine labelled cDNA expression products. b, ^{125}I-insulin binding by chimaeric receptors. a, COS-7 cells were transfected with the constructs indicated (10 μg supercoiled DNA) or with a control expression vector lacking the receptor cDNA insert[21]. A431 epidermoid carcinoma cells were used for EGF receptor control experiments. COS-7 cells 44 h after transfection were washed twice with methionine-free medium prepared from a MEM select amine kit (Gibco) and incubated for 9 h with 200 μCi ^{35}S-methionine at 800 Ci mmol^{-1} per 8 cm dish. Proteins were immunoprecipitated with monoclonal antibodies to human insulin receptor[22] (MAb CII25.3) or human EGF receptor[23] (MAb RI), as described[24], and were analysed on 7.5% reducing SDS polyacrylamide gels. Sizes of polypeptide markers are indicated (myosin H-chain, 200 K, phosphorylase B, 97.4 K). Arrows, immunoprecipitated expression products. b, Transfected COS-7 cells were washed twice with phosphate-buffered saline (PBS) after 53 h and incubated in 1 ml per 2.2 cm well of serum-free cell culture medium containing 0.2% bovine serum albumin (Sigma), bacitracin (0.5 mg ml^{-1}) (Sigma) and ^{125}I-labelled insulin (0.5 μCi per well) at 93 μCi μg^{-1} (provided by Dr Carl Grunfeld, UCSF) for 2 h at 21 °C. Cells were washed 3 times with PBS at 4 °C, lysed in 0.5 ml 0.1% SDS, 0.1 M NaOH for 30 min at 37 °C, and the total radioactivity was measured. Average of three determinations shown.

brane sequences of the EGF receptor fused to the insulin receptor β subunit extracellular portion (IβE), and, if cleavage of IER proreceptor sequences is inefficient, a 190 K polypeptide. Each of these products was detected in cells expressing the IER chimaera, the IβE fusion glycoprotein subunit migrates as a diffuse band just below the 135 K α-subunit polypeptide (Fig. 2a, see also Fig. 3).

Binding experiments with ^{125}I-labelled insulin (Fig. 2b) indicated that the products of the HIR and IER constructs were expressed in functional form on the surface of COS cells. Insulin binding was highest for the HIR construct and the amount of binding detected was proportional to the levels of the glycopolypeptides present in the transfected cells (Fig. 2a).

To test their intrinsic kinase activity, the expressed polypeptides were immunoprecipitated from lysates of transfected COS-7 cells using antibodies against the EGF receptor (Fig. 3a) or the insulin receptor (Fig. 3b,c), and [γ-^{32}P]ATP was added. Insulin-stimulated autophosphorylation of the human insulin receptor β subunit was clearly detected above the endogenous COS-7 control, at substrate concentrations (100 μM ATP) required by the insulin receptor kinase[15,16] that result in reduced specific activity of the radioactive tracer ([γ-^{32}P]ATP) and thus a weak signal (HIR, Fig. 3b). In contrast, only subpicomolar (0.1 pM) concentrations of ATP were needed to detect EGF-stimulated EGF-receptor kinase activity[17] (Fig. 3a,c), conditions under which the insulin receptor kinase is inactive.

As shown in Fig. 3a and c, the IER chimaeric receptor displays insulin-stimulated autophosphorylation activity. Insulin stimu-

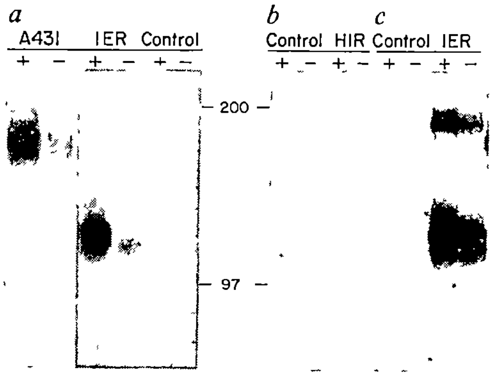

Fig. 3 Autophosphorylation of normal and chimaeric receptors. Immunoprecipitation from a, A431 cells using human EGF receptor mouse monoclonal antibody RI[23], or from COS-7 cells transfected with the IER construct or with a control expression vector lacking a receptor cDNA insert, using human EGF receptor rabbit polyclonal antibody RK-2 (ref. 24), b, HIR-transfected or control cells using human insulin receptor mouse monoclonal antibody CI125.3, c, IER-transfected or control cells using CI125.3. Detergent cell lysates were stimulated with insulin (+) (EGF for A431 cells) or mock-stimulated with PBS (−).

Methods Insulin or EGF stimulation of autophosphorylation was induced by incubating the cell lysates before immunoprecipitation with either 200 nM insulin (Sigma) for 1 h or 1 μM EGF for 15 min at 4 °C. Antibody RI, RK-2 or CI125.3 prebound for 30 min to protein A-Sepharose was added, and incubated for 15 min at 4 °C. The washed immunoprecipitates, in a volume of 30 μl, were adjusted to 5 mM MnCl$_2$, and 15 μCi of [γ-^{32}P] ATP was added for 1 min at 4 °C. The final ATP concentration was 0.1 pM (a and c) or 100 μM (b). The reaction was stopped by adding 20 μl of 3 times concentrated SDS sample buffer, and samples were analysed on 5%/7% SDS polyacrylamide gels[25].

lation of chimaeric protein autophosphorylation was observed in immunoprecipitates obtained using antibodies to either the insulin receptor extracellular domain (Fig. 3c) or the EGF receptor intracellular domain (Fig. 3a). This experiment rules out the possibility that small amounts of insulin-stimulated, endogenous COS cell insulin receptor catalysed phosphorylation of the chimaeric receptors in the immunoprecipitates. The chimaeric IER kinase was active at low ATP concentrations (0.1 pM) consistent with the enzymatic characteristics of the EGF receptor kinase domain. Interestingly, phosphorylation of the bands representing the IβE fusion glycoprotein subunit (120 K) and the uncleaved chimaeric IER proreceptor (190 K) was also induced by insulin. Like the native EGF receptor[17], a maximal ligand induction was observed after 30 seconds at 4 °C (not shown). Thus the EGF receptor tyrosine kinase retains its original enzymatic characteristics when controlled by the insulin binding domain of a chimaeric receptor molecule.

We have described here the expression and functional characterization of a chimaeric receptor molecule composed of the extracellular insulin receptor sequences linked to the EGF receptor transmembrane and cytoplasmic domains. We have shown that binding of insulin to this IER chimaeric receptor molecule induces tyrosine kinase activity in the EGF receptor-derived intracellular domain. The observed tyrosine kinase activity is characteristic of the EGF receptor in that it was measurable at subpicomolar ATP concentrations, which do not activate the insulin receptor phosphotransferase[15,16]. Therefore, the IER chimaeric receptor precursor must have been correctly processed and folded into a conformation permitting communication between two entirely heterologous receptor domains, at the same time preserving the kinetic properties of the EGF receptor tyrosine kinase.

These results directly demonstrate that insulin and EGF receptors use a common transmembrane signal transfer mechanism

This finding was unexpected as the primary structure and, indeed, the general architecture of the extracellular domains of these two proteins show little similarity The only extracellular structures that are homologous between these receptors are regions with high cysteine content and conserved cysteine arrangement[2] that occur twice in the EGF receptor and once per insulin receptor α subunit

How insulin and EGF receptors transduce a signal across the plasma membrane is not fully understood It has been suggested for both receptors that the activation of the protein kinase is likely to be controlled by the state of receptor aggregation, which may be a consequence of ligand binding What alternative mechanisms of transmembrane signal transfer exist for this receptor type? Domain communication through a transmembrane α helix is difficult to envisage, as is interaction of the homologous, cysteine-rich units with a common, heterologous membrane component needed for signal transfer We favour the notion that a ligand-induced conformational change in the receptor extracellular domain triggers receptor dimerization resulting in activation of intracellular enzymatic activities

Whereas the EGF receptor may have to self-associate to induce kinase activity on the cytoplasmic side of the membrane, insulin and IGF-1 receptors[18], both disulphide-linked heterotetramers, may be structured in this way to avoid the need for aggregation and predispose these receptors to respond to ligand The ability of the chimaeric receptors to transduce a signal suggests that the structural differences between EGF and insulin receptors are variations on a common mechanism for signal transfer These results open new avenues of investigation into the mechanisms of transmembrane signalling and receptor function

We thank Drs Ora Rosen and Michael D Waterfield for the supply of monoclonal antibodies, Dr Carl Grunfeld for a gift of ^{125}I-labelled insulin, and M Vasser and P Jhurani for synthesis of oligonucleotides We are indebted to Dr Suzanne Pfeffer for discussions and to Jeanne Arch for help in preparing the manuscript

Proliferation and maturation of antigen-stimulated B cells are regulated by several soluble factors derived from macrophages and T cells[1,2]. These soluble factors are functionally divided into two groups: B-cell growth factor (BCGF), thought to be involved in B-cell proliferation; and B-cell differentiation factor (BCDF), responsible for maturation of activated B cells into immunoglobulin-secreting cells[3–6]. This classification needs to be re-examined in the light of the recent cloning of complementary DNA encoding IgG$_1$ induction factor (interleukin-4, IL-4) from the 2.19 mouse T-cell line[7]. Recombinant IL-4 has BCGF and BCDF activities and affects B cells, T cells and mast cells (refs 7, 8; our unpublished data). Another well-characterized B-cell factor is T-cell replacing factor (TRF)[9–12], which, when secreted by the murine T-cell hybridoma B151K12, is defined by two activities[10–12]: induction of IgM secretion by BCL$_1$ leukaemic B-cell line; and induction of secondary anti-dinitrophenol (DNP) immunoglobulin G (IgG) synthesis *in vitro* by DNP-primed B cells Although TRF from B151K12 was classified as BCDF, purified TRF has BCGF-II activity[13]. To elucidate the molecular properties of TRF we isolated cDNA encoding TRF from the 2.19 T-cell line and report here the structure and multiple activities of this lymphokine.

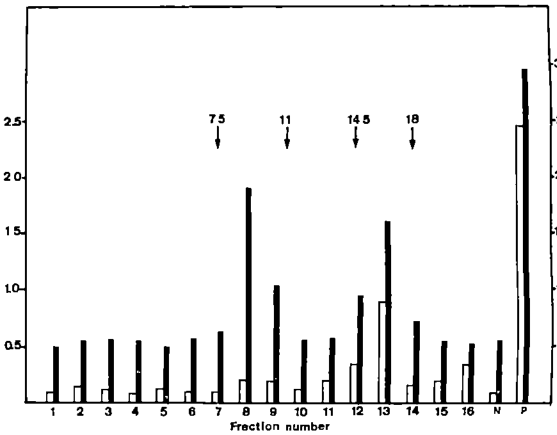

Fig. 1 Effects on BCL$_1$ cells of translational products directed by size-fractionated mRNA of 2 19 T-cell line Poly(A)$^+$ RNA was obtained from the Concanavalin A-activated 2 19 T-cell line and fractionated by centrifugation in a 5–22% sucrose gradient at 36,000 rpm for 15 h[7] An aliquot of each of the 16 fractions was injected into *Xenopus* oocytes Incubation media were collected after incubation for 36 h at 20 °C and added to the assay medium at the concentration of 1% Right-hand scale, ^{3}H-thymidine incorporation (closed bars, c p m per culture × 10^{-3}) Left-hand scale, anti-IgM plaque-formation response (open bars, plaque-forming cells) per culture × 10^{-3} of BCL$_1$ cells, measured as described in Table 1 P, positive control where culture supernatants of B151 hybridoma were added to the medium at the concentration of 50%, N, negative control where phosphate buffer was injected into *Xenopus* oocytes instead of mRNA Arrows, sizes of mRNA (in Svedberg units)

Table 1 TRF and BCGF-II activities on BCL_1 of supernatants of cell culture and mRNA-injected oocytes

Supernatants of cells or oocytes injected with mRNA were added to the culture medium of BCL_1 cells at indicated concentrations BCL_1 cells ($1 5\times10^5$) of an *in vivo* line were cultured in 0 2 ml RITC medium (serum-free, 5 mg ml^{-1} bovine serum albumin, 50 μM 2-mercaptoethanol and antibiotics) in addition to testing supernatants After a 2-day culture, the protein A plaque assay[19] was used to determine the numbers of IgM-secreting cells BCL_1 proliferation was determined by ^3H-thymidine uptake for the last 6 h of a 2-day culture Culture medium of various cell lines were added to the assay medium at indicated concentrations rIL-4, Supernatants of *Xenopus* oocytes injected with mRNA derived from pSP6KmIL4-374 as described previously[7] B151 TRF prepared by partial purification from supernatants of B151 cells[13] The total cDNA library consisted of 5×10^4 clones and the library DNAs digested with *Sac*I or *Sal*I The detailed methods of mRNA synthesis by SP6 RNA polymerase and its injection to *Xenopus* oocytes were described previously[7] Individual cDNA clones with 1-kb longer inserts containing *Sac*I sites were digested with *Sal*I and their mRNAs tested Incubation medium of oocytes injected with distilled water was used as a negative control The construct pSP6K-mTRF23 was digested either by *Sal*I or by *Acc*I and used as template for *in vitro* mRNA synthesis All values are means in the triplicate experiments and standard errors of triplicate experiments ranged from 1 01 to 1 12

Supernatants of the 2 19 T-cell line[14] contain the TRF activity (Table 1) and, like the B151 supernatants, have the BCGF-II activity as assayed by induction of proliferation of BCL_1 cells $Poly(A)^+RNA$ of 2 19 T cells was fractionated by sucrose density gradient centrifugation and an aliquot of each fraction was injected into *Xenopus* oocytes to test the presence of messenger RNA encoding BCGF-II and TRF by measuring proliferation stimulation and IgM plaque formation of BCL_1 cells, respectively BCL_1 proliferation occurs in translation products directed by 9 and 16S mRNAs (Fig 1) In contrast, IgM plaque-forming activity is found only in products of 16S mRNA The 9S mRNA corresponds to the size of mRNA for IgG_1 induction factor (IL-4)[7] Recombinant IL-4 produced by *Xenopus* oocytes shows BCL_1 proliferation activity but not IgM plaque-forming activity (Table 1) Furthermore, translation products directed by 15–18S mRNA of B151K12 cells exert TRF activity[15] We therefore conclude that 16S mRNA of 2 19 T cells encodes another factor that has TRF activity The same fraction of mRNA also encodes BCGF-II defined by the growth stimulation of BCL_1 The results also indicate that the BCL_1 proliferation assay does not discriminate between BSF-I (IL-4) and BCGF-II

To clone cDNA encoding TRF we used the pSP6K cDNA library of the total $poly(A)^+$ RNA of 2 19 T cells, the construction of which was described previously[7] A DNA mixture of 5×10^4 independent cDNA clones was cleaved with *Sac*I or *Sal*I to linearize plasmid DNA and mRNAs were synthesized using SP6 RNA polymerase The synthesized RNAs were injected into

Table 2 Stimulation of anti-DNP IgG plaque formation by rTRF

Pretreatment with anti-Thy 1 2	Antigen	TRF in culture (%)	Anti-DNP IgG plaque-forming cells per culture
–	None	None	127

+	DNP-OA	B151 10	720
+	DNP-OA	B151 5	636
+	DNP-OA	B151 2 5	485
+	DNP-OA	B151 0 25	325

BALB/c mice were immunized with DNP-KLH and spleen cells isolated 6–8 weeks after the immunization and treated twice with anti-Thy 1 2 and complements The cells (6×10^5) were cultured in 0 2 ml culture media (RPMI 1640) containing 10% fetal calf serum (FCS) together with 10 ng DNP-ovalbumin (DNP-OA) and TRF for 5 days Anti-DNP IgG plaque-forming cells were measured as described[11] B151 indicates partially purified TRF from supernatants of B151 cells as described[13]

Fig 2 *a*, Restriction map of the insert of pSP6K-mTRF23 and its sequence strategy The insert of pSP6K-mTRF23 was isolated by *Bam*HI digestion and subcloned in pUC18 Clones that contained series of unidirectional deletions were produced by digestion with exonucleases III and VII from either end[16] The nucleotide sequence of the entire cDNA was determined by the dideoxy method[17] Top line, insert DNA, dotted and open rectangles, DNA sequences encoding the signal peptide and coding region, respectively Horizontal arrows, directions and ranges of sequences read Double arrow, 100 bp B, *Bam*HI site *b*, Nucleotide and predicted amino-acid sequences of TRF Possible N-glycosylation sites are underlined Numbers above and below sequences, amino-acid and nucleotide positions, respectively *c*, Regions of identity between TRF and other lymphokines Similar amino-acid sequences of known proteins were searched by computer program Sequences (>14 residues) with 45% similarity (including related amino acids at the corresponding region) were chosen Identical and related amino acids are shown by asterisks and dots, respectively Sequences of murine GM-CSF[21], murine interferon-γ (IFN-γ)[22] and murine IL-3[23,24] were taken from published details

Xenopus oocytes and the translation products secreted into the incubation medium collected and assayed for proliferation and plaque-formation of BCL$_1$ cells. Translation products derived from *Sal*I-digested templates have both of these activities whereas those from *Sac*I-digested templates have neither, indicating that cDNAs encoding BCGFII and TRF contain *Sac*I sites in the structural sequences (Table 1)

The pSP6K cDNA library of 2 19 T-cell mRNA was divided into 18 pools, each consisting of 3,000 clones We assayed each pool and found only one that was positive both in proliferation and in IgM plaque-forming activity of BCL$_1$ cells After two more subpooling steps, we identified a positive pool of 60 clones and examined inserts of the individuals to select clones whose inserts were >1 kilobase (kb) and contained the *Sac*I site but not the *Sal*I site Seven out of 60 clones (clones 16, 18, 23, 27, 42, 51 and 53) fulfilled these criteria One of them, clone 23, was positive for BCL$_1$ proliferation and IgM plaque-formation (Table 1) and was termed pSP6K-mTRF23

The nucleotide sequence of the entire cDNA was determined by the combination of the unidirectional deletion method[16] using exonucleases III and VII and the dideoxy method[17] The cDNA insert is 1,533 base pairs (bp) long excluding the poly(A) tail (Fig 2) There are two long open reading frames (ORFs) deduced from the cDNA sequence, the longer frame (133 residues) between bases 44 and 442 and the shorter (62) between bases 544 and 729 The TRF activity occurs in the translation products of pSP6K-mTRF23 linearized by *Acc*I (Table 1) Because the *Acc*I site is located in the middle of the shorter ORF at bases 624-629, the functional significance of this reading frame was excluded The longer ORF encodes a polypeptide of 133 amino acids with three possible *N*-glycosylation sites There are 21 hydrophobic amino acids at the N-terminus of this ORF

Table 3 BCGFII activity of recombinant TRF

Lymphokines	Additions (%)	c.p.m. per culture DXS −	c.p.m. per culture DXS +	Synergy indices
none		520	842	1.6
rTRF	5	2,715	6,044	2.2
rTRF	1.25	1,724	4,268	2.5
rTRF	0.6	1,290	2,813	2.2
rTRF	0.16	919	1,827	2.0
2.19 sup	3.0	7,425	11,214	1.5
2.19 sup	1.0	7,183	10,740	1.5
2.19 sup	0.3	6,424	8,626	1.3

CBA spleen B cells enriched by panning[20] were cultured in duplicates of $2\times10^6\,\mathrm{ml}^{-1}$ in 0.2 ml RPMI1640 containing 50 μM 2-mercaptoethanol and 15% FCS with or without (50 μg ml^{-1}) dextran sulphate (DXS). Supernatants of oocytes injected with pSP6K-mTRF23 mRNA (rTRF) and culture supernatants of 2.19 T cell line (2.19 sup) were added at indicated concentrations. ^{3}H-thymidine was added for the last 24 h of a 72-h culture and the degree of proliferation was assessed by determining incorporation of the radiolabel. Synergy indices were calculated by dividing c.p.m. in DXS-stimulated cultures by c.p.m. in unstimulated culture.

(including two arginine residues). The putative secreted core polypeptide has a relative molecular mass (M_r) of 12,300, which is near that of TRF (M_r 18,000 after glycosylation[12]). The longer ORF contains three cysteine residues (15, 62 and 104) that may be involved in the oligomer formation. We therefore conclude that the longer ORF encodes the TRF molecule.

We searched homologies between the deduced amino-acid sequence of TRF and sequences of known proteins, including all the lymphokines so far identified. No proteins are very similar to TRF except for short segments of murine interleukin-3 (IL-3), murine granulocyte–macrophage colony stimulating factor (GM-CSF) and murine interferon-γ (Fig. 2c). We suggest that TRF is distantly related to these lymphokines.

We tested various biological activities of recombinant TRF (rTRF), the oocyte translation product of pSP6K-mTRF23. First, we tested it for the other activity of TRF, namely, stimulation of the secondary anti-DNP IgG response. Mice were immunized with DNP-keyhole limpet haemocyanin (KLH), and splenic B cells were purified 6–8 weeks later for the assay of the anti-DNP IgG plaque-forming cells. The assay revealed that rTRF stimulates DNP-primed B cells in the presence of antigen (DNP-OA) and augments anti-DNP IgG response (Table 2). The rTRF also induces IgM synthesis in *in vivo*-activated B-cell blasts (data not shown). These properties of rTRF agree with the criteria of TRF derived from B151 (refs 11–13).

During screening, we found that pools containing the stimulating activity of IgM plaque-forming cells of $\mathrm{BCL_1}$ cells always have the stimulation activity of the $\mathrm{BCL_1}$ proliferation. The translation product of the final clone, pSP6K-mTRF23, also shows these two activities (Table 1). Furthermore, rTRF augments ^{3}H-thymidine incorporation into B cells stimulated with dextran sulphate (Table 3). These results indicate that the TRF and BCGFII activities belong to a single molecule. The rTRF has no interleukin-1 (IL-1)-, IL-2-, IL-3- or BSF-I-like activity (data not shown), but it induces augmentation of ^{3}H-thymidine uptake in thymocytes in conjunction with suboptimal doses of Concanavalin A and IL-2. Although Sanderson *et al.*[18] have recently suggested that BCGF-II is identical to eosinophil differentiation factor, we do not yet know whether TRF has this activity. Because of the diverse activities and targets of TRF, this lymphokine is classified as an interleukin. As this is the fifth interleukin whose structure has been determined, we propose that TRF or BCGF-II be called interleukin-5.

We thank Professor T. Oi for advice on the homology search and Ms K. Hirano for preparation of the manuscript. Supported by grants from the Ministry of Education, Science and Culture of Japan, the Swedish National Science Research Council, the Swedish MRC and the Aristotale Onassis benefit foundation.

When stimulated with antigen, B cells are influenced by T cells to proliferate and differentiate into antibody-forming cells. Since it was reported[1,2] that soluble factors could replace certain functions of helper T cells in the antibody response, several different kinds of lymphokines and monokines have been reported in B-cell growth and differentiation[3,4]. Among these, human B-cell differentiation factor (BCDF or BSF-2) has been shown to induce the final maturation of B cells into immunoglobulin-secreting cells[5–8]. BSF-2 was purified to homogeneity[9] and its partial NH_2-terminal amino-acid sequence was determined[10]. These studies indicated that BSF-2 is functionally and structurally unlike other known proteins. Here, we report the molecular cloning, structural analysis and functional expression of the cDNA encoding human BSF-2. The primary sequence of BSF-2 deduced from the cDNA reveals that BSF-2 is a novel interleukin consisting of 184 amino acids.

In a previous study[11], we established a human T-cell line (TCL-Na1), which constitutively produced large amounts of BSF-2, using human T-cell leukaemia virus-1 (HTLV-1). BSF-2, with a relative molecular mass (M_r) 21,000 (21K), was purified

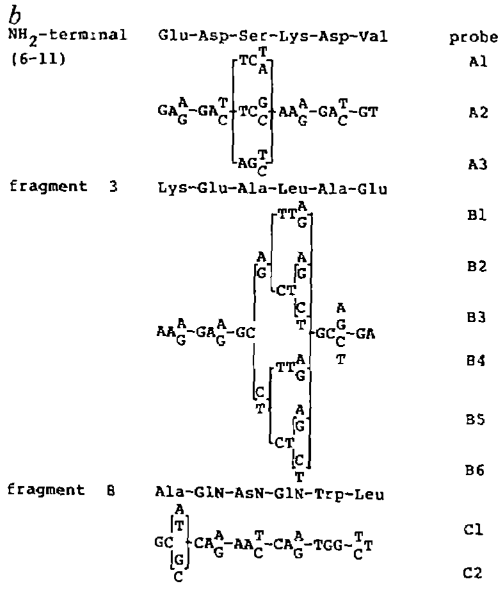

Fig. 1 *a*, Sequences of BSF-2 fragments, *b*, sequences of synthetic oligonucleotide probes

Methods. *a*, BSF 2 (21K) was purified as reported previously[9,10] Approximately 1 nmol of purified BSF-2 (20 μg) was digested with 5 pmol of lysylendopeptidase in 5 mM Tris-HCl buffer (*p*H 9 5) at 37 °C for 6 h The fragments were separated by high performance liquid chromatography (HPLC) using reverse phase column, μBondopack (C_{18} 300×2 1 mm, Waters), with a linear gradient of 0–60% acetonitrile containing 0 1% trifluoroacetic acid The partial amino-acid sequence of each fragment was determined using a gas-phase protein sequencer (Applied Biosystems model 470A) essentially as described[17] The obtained phenylthiohydantoin-amino acid residues were analysed by HPLC using ODS-120T column[18] (C_{18} 250×4 6 mm, Toyo Soda) *b*, Mixtures of 32 (A1–A3, C1 and C2) or 64 (B1–B6) possible oligonucleotides (17 bases) corresponding to the NH_2-terminal (A1–A3), fragment 3 (B1–B6) and fragment 8 (C1, C2) were made by an automated DNA synthesizer (Applied Biosystem Inc) The expression vector pQ was constructed by a series of manipulations of pCEIL-2[19] Essentially, it contains two copies of a simian virus 40 (SV40) DNA segment containing the early promoter and *ori* sequences in opposite orientations This plasmid is unstable unless a DNA (in this case cDNA) segment is inserted between the two SV40 sequences, because it becomes cruciform in *Escherischia coli*[20] Once the cDNA is inserted it can be expressed in monkey COS cells independent of orientation Efficiency of expression was previously confirmed with IL-2 and IFN cDNA (G Yamada and T Tanigushi, unpublished data) Poly (A)$^+$ RNA was prepared from TCL-Na1 cells and cDNA was made using the Amersham cDNA synthesis system (Amersham UK) which is essentially based on the method described by Gubler and Hoffman[21] pQ vector was digested with *Pst*I to remove the insert IL-2 cDNA One part of the cDNA was annealed with pQ vector at the *Pst*I site by the standard G-C tailing method[19] and the resulting recombinant plasmids were transfected into *E coli* MC1061 The other part of the cDNA was methylated with *Eco*RI methylase (New England Biolabs), ligated with *Eco*RI linker (Takara Shuzo Co), digested with *Eco*RI and applied to Bio-Gel A-50 m (Bio-Rad) cDNA fragments longer than 500 base pairs were ligated with *Eco*RI-digested λgt10 vector (Stratagene) and packaged *in vitro* using Gigapack (Stratagene)[22] Both cDNA libraries (30×10^4 clones) were screened with the ^{32}P-labelled 17-base-long oligonucleotides by the *in situ* procedure under the conditions described[23]

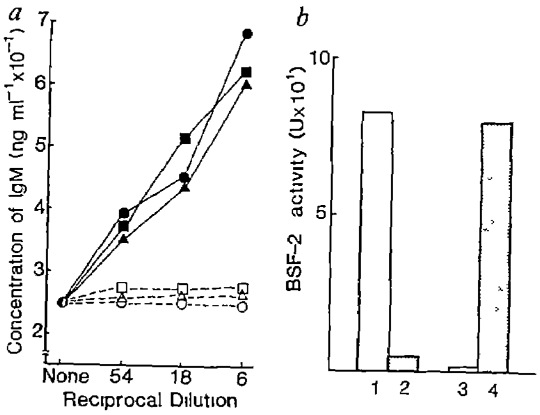

Fig 2 *a*, Expression of BSF-2 cDNA in COS7 cells, *b*, affinity chromatography of COS7 cell-derived BSF-2

Methods Monkey COS7 cells[24] (5×10^5) were seeded onto 60 mm plates one day before transfection Transfections were carried out with 2 μg of plasmid DNA in 1 ml 25 mM Tris-HCl (*p*H 7 4), 137 mM NaCl, 5 mM KCl, 0 6 mM Na_2HPO_4, 0 5 mM $MgCl_2$, 0 7 mM $CaCl_2$ and 500 μg of DEAE-Dextran (Pharmacia) After 1 h incubation at 37 °C, the solution was replaced with Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal calf serum (FCS) and 150 μM chloroquine, incubated at 37 °C for 3 h and replaced with fresh DMEM containing 10% FCS Seventy-two hours later the culture supernatants were collected and assayed for BSF-2 activity *a*, Ten thousand cells of the Epstein-Barr virus transformed B cell line SKW6-C14 were cultured in different concentrations of either the culture supernatants of COS7 cells transfected with pBSF2 38 DNA (●, ■, ▲) or mock-transfected COS7 cells (○, □, △) Three separate experiments are shown After 3 days the levels of IgM in the culture supernatants were determined by enzyme-linked immunosorbent assay (ELISA) as described[9] *b*, The culture supernatants of COS7 cells transfected with pBSF2 38 DNA (containing 90 units of BSF-2) were applied to specific anti-peptide immunoaffinity gel (2, 4) or to control anti-OVA immunoaffinity gel (1, 3) After washing the gels, the bound protein was eluted with 3M KSCN BSF-2 activities in the effluent (1, 2) and eluate (3, 4) were determined using SKW6-C14 cells One unit per ml of BSF-2 induces 50% of the maximum IgM-production in 1×10^4 SKW6-C14 cells[9] The specific immunoaffinity gel was made using affinity-purified rabbit antibody (antipeptide) against the synthetic NH_2-terminal BSF-2 peptide[10]

to homogeneity from the culture supernatant of TCL-Na1 cells and digested with lysylendopeptidase to give 9 fragments The partial amino acid sequences of 7 fragments were determined (Fig 1*a*) On the basis of the partial amino acid sequence at the NH_2-terminal of BSF-2 reported previously[10], it was shown that fragment 2 consisted of 9 amino acids at the NH_2-terminal and fragment 6 consisted of residues starting with the tenth amino acid from the NH_2-terminal The cDNA libraries made from poly(A)$^+$ RNA of TCL-Na1 cells were probed with 11 groups of synthetic oligonucleotide mixtures (17 bases each) corresponding to fragments 3, 8 and the NH_2-terminal as indicated in Fig 1*b* One cDNA clone, designated pBSF2 38, that specifically hybridized with A2, B2 and C1 probes but no others, was isolated from the cDNA library constructed in pQ vector The libraries were screened again by pBSF2 38 insert cDNA as a probe and ten positive clones were identified Four of these were shown to hybridize with the A2 probe, which corresponds to the NH_2-terminal of BSF-2 All five cloned plasmids contained cDNA inserts consisting of about 1,000–1,100 base pairs To examine whether pBSF2 38 contained the entire coding region of BSF-2, pBSF2 38 DNA was transfected into COS7 cells The culture supernatant of COS7 cells transfected with pBSF2 38 DNA induced IgM production in SKW6-C14 cells and the control culture supernatant of mock-transfected COS7 cells did not (Fig 2*a*) The BSF-2 activity generated by COS7 cells transfected with pBSF2,38 DNA could be adsorbed onto and subsequently eluted from an immunoaffinity gel conjugated with polyclonal antibody against the synthetic NH_2-terminal BSF-2 peptide, but did not bind to the control antiovalbumin (OVA) immunoaffinity gel (Fig 2*b*) Thus pBSF2 38 contains the entire coding region of BSF-2

The complete nucleotide sequence of the insert cDNA of pBSF2 38 was determined by the dideoxy method[12] and by chemical cleavage[13] The restriction endonuclease cleavage map of the cDNA insert and the sequencing strategy are shown in Fig 3*a* The insert cDNA of pBSF2 38 contains a single large open reading frame (Fig 3*b*) In this frame, the initiator ATG is followed by 211 codons before the termination triplet TAG We confirmed the nucleotide sequence of BSF-2 cDNA using one of the clones (λBSF2 5) identified by probing the cDNA library constructed in λgt 10 vector with pBSF2 38 insert DNA (Fig 3*a*) Although λBSF2 5 insert cDNA was found to lack 126 nucleotides at the 5′ terminal region compared with pBSF2 38 insert cDNA, the nucleotide sequence of the other region was in complete agreement with that of pBSF2 38 cDNA insert (data not shown) Because we know from protein sequence data that the sequence of the NH_2-terminal region of mature BSF-2 is Pro-Val-Pro-Pro , we conclude that BSF-2 is made as a precursor consisting of 212 amino acids and processed into a mature form by a cleavage between the Ala (−1) and Pro (+1) residues Hydrophobic amino acids are abundant in residues from −28 to −1 and this region seems to be a typical signal peptide that is required for BSF-2 secretion Although we do not know at present whether the carboxy-terminal processing occurs in BSF-2, we conclude that mature BSF-2 probably consists of 184 amino acids As underlined in Fig 3*b*, the amino-acid sequence of all the fragments that originated from purified BSF-2 was in complete agreement with the amino-acid sequence deduced from the cDNA The calculated molecular mass of the BSF-2 polypeptide was 20,781 5 This is comparable with the apparent molecular mass of purified BSF-2 (21K) as determined by SDS-polyacrylamide gel electrophoresis (PAGE)[9,10] Two potential *N*-glycosylation sites (Asn-X-Ser and Asn-X-Thr, at positions 45–47 and 144–146, respectively) were identified, but we have not yet determined whether BSF-2 is a glycoprotein

The protein sequence of BSF-2 was compared with all proteins in the National Biomedical Research Foundation database and Genetic Sequence Data Bank (Bolt Beranek and Newman, Inc, Los Alamos National Laboratory), no strong similarity with any protein was revealed We also searched our personal database, which contains human IL-1α, IL-1β, IL-2, γ-interferon (γ-IFN), colony stimulating factor-1 (CSF-1), granulocyte macrophate (GM)-CSF, granulocyte (G)-CSF and B-cell stimulatory factor-1 (BSF-1), and murine IL-1, IL-2, γ-IFN, GM-CSF, IL-3 and

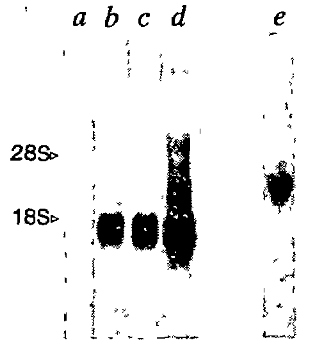

Fig. 4 Analysis of BSF-2 mRNA. Poly(A)$^+$ RNA was prepared from various kinds of cells. RNA (10 µg) was denatured and subjected to blotting analysis[26]. *a*, Poly(A)$^+$ RNA from non-stimulated tonsillar mononuclear cells, *b*, poly(A)$^+$ RNA from tonsillar mononuclear cells stimulated with phytohaemagglutinin (0.1%) and tetradecanoyl phorbol 13-acetate (5 ng ml^{-1}) for 40 h, *c*, poly(A)$^+$ RNA from TCL-Na1 cells, *d*, poly(A)$^+$ RNA from T 24 bladder cell carcinoma, *e*, total RNA from cardiac myxoma cells[10].

BSF-1 for similarities. Only human G-CSF[14] showed significant similarity to BSF-2. Amino acids 28–91 of BSF-2 and amino acids 20–85 of G-CSF match at 17 residues (25.7% of all residues) (Fig. 3*c*). Note that cysteine residues at positions 44, 50, 73 and 83 of BSF-2 match those at positions 39, 45, 67 and 77 of G-CSF exactly. This suggests that BSF-2 is distantly related to G-CSF. If so, intramolecular disulphide bonds would be important in the structure of these proteins.

In Northern blot analysis (Fig. 4) pBSF2.38 DNA hybridized with a single species of messenger RNA ~1,300 nucleotides long which was extracted from activated lymphocytes and TCL-Na1 cells but not from unstimulated control lymphocytes, showing that, like other T-cell-derived lymphokines, BSF-2 mRNA is induced upon mitogenic stimulation.

We have previously reported[10] that cardiac myxoma cells produce high levels of a molecule with BSF-2 activity which was specifically absorbed by the anti-peptide antibody. It has also been shown that bladder cell carcinoma, T24 cells produce a molecule with BSF-2 activity[15]. To show that these cells produce BSF-2 itself, we performed Northern blot analysis. As shown in Fig. 4 (*d*, *e*), BSF-2 mRNA was transcribed in T24 cells and myxoma cells at a much higher level than activated lymphocytes, although the mRNA in myxoma cells was larger than that of lymphocytes. These data indicate that under certain conditions, the BSF-2 gene can be expressed in non-lymphoid tissues. Because patients with cardiac myxoma frequently show several kinds of autoimmune disease-like symptoms[16], it was suggested[10] that deregulated production of BSF-2 might be involved in autoimmune pathogenesis. The fact that BSF-2 gene expression in myxoma cells is high further strengthens this argument.

This work was supported in part by grants from the Ministry of Education, Science and Culture. We thank Dr Edward Barsumian for critical review of the manuscript and Ms K. Kubota, J. Mori and M. Kawata for their secretarial assistance.

Intracellularly injected tetanus toxin inhibits exocytosis in bovine adrenal chromaffin cells

Reinhold Penner*, Erwin Neher† & Florian Dreyer*

* Rudolf-Buchheim-Institut für Pharmakologie, Frankfurter Str 107, D-6300 Giessen, FRG
† Max-Planck-Institut für Biophysikalische Chemie, Am Fassberg, D-3400 Göttingen, FRG

The clostridial neurotoxins tetanus and botulinum toxin type A are known to block transmitter release from nerve terminals[1–3], probably by interfering with some essential process controlling exocytosis[3,4] after the entry of Ca^{2+} ions. Although exocytosis occurs in many secretory cells, these toxins show a high specificity for neurones and the secretory response of cultured bovine adrenal medullary cells is not inhibited by exposure to medium containing tetanus or botulinum toxin type A (although it is by botulinum toxin type D)[4]. Here we report that when tetanus toxin and botulinum neurotoxin type A are injected intracellularly into chromaffin cells they strongly inhibit secretion, as revealed by the measurement of cell capacitance[5]. These results indicate that these toxins are normally ineffective in chromaffin cells because they are not bound and internalized, so do not reach their site of action. Furthermore, we have localized the secretion-blocking effects of the toxin to a fragment comprising the light chain covalently linked to part of the heavy chain, suggesting that this part of the molecule contains the active site.

We examined cultured bovine adrenal chromaffin cells, isolated as described[6], using the whole-cell configuration of the patch-clamp technique[7]. This allows one to monitor exocytosis using membrane capacitance as a measure of the cell surface area. Capacitance and surface area change considerably as chromaffin granules fuse with the membrane or endocytotic retrieval of the membrane occurs[5]. Secretion was stimulated by dialysing the cells through a patch-pipette with a solution buffered to a free Ca^{2+} concentration of 1 µM. The total membrane capacitance of control cells (typically 4–8 pF) started to increase immediately upon establishment of the whole-cell configuration, eventually leading to a 2–3-fold capacitance increase within 15–25 min (Fig. 1*a*).

When cells were preloaded with either tetanus toxin or botulinum neurotoxin type A the secretory response to the same challenge (dialysis of cells with Ca^{2+}-containing solution) was effectively removed. In fact, cells pretreated with tetanus toxin consistently showed a slight decrease in total membrane capacitance (Fig. 1*c*), suggesting that in these cells there was more endocytotic than exocytotic activity. This 'reversal effect' was observed only once in cells pretreated with botulinum neurotoxin type A ($n = 10$) which may reflect genuine differences in the ability of the two toxins to inhibit secretion or, as has been suggested[8,9], different sites of action. The typical response to increased intracellular Ca^{2+} levels in cells preloaded with botulinum neurotoxin type A was a slight initial increase in cell

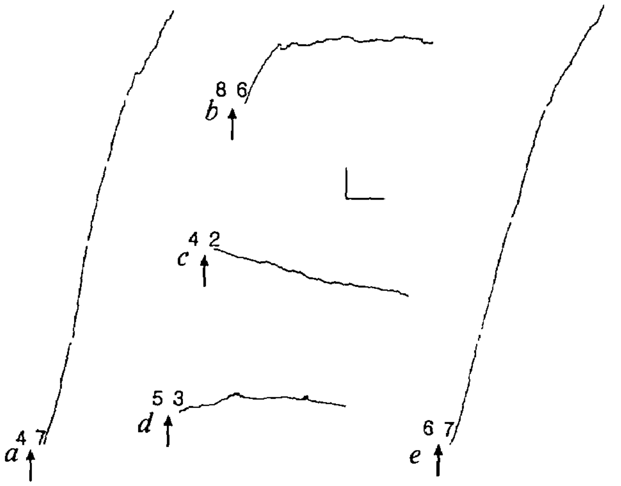

Fig 1 Effects of clostridial toxins on the secretory responses (measured as capacitance changes) of bovine chromaffin cells stimulated by elevation of the intracellular Ca^{2+} concentration *a*, Typical time course of capacitance changes recorded from a stimulated control cell *b*, Typical inhibitory effect of botulinum A toxin on the response of a stimulated cell *c*, Inhibition of exocytosis by tetanus toxin *d*, Inhibition of exocytosis in cells preloaded with fragment B at 25 μg ml^{-1} in the pipette *e*, Capacitance increase recorded from a cell preloaded with fragment C at 25 μg ml^{-1} in the pipette Capacitance measurements were performed according to the method described by Neher and Marty[5] Briefly, adrenal medullary chromaffin cells isolated as described[6] and kept in short-term culture (1–5 days) were voltage clamped at −70 mV and subjected to a sinusoidal voltage command of 18 mV r m s at 795 Hz The resulting current was fed into a lock-in amplifier which delivered the capacitive component of the signal when tuned to the desired phase angle with respect to the reference signal For the large capacitance changes of the control and fragment C traces, these had to be reconstructed from several segments (interruptions) since the lock-in measurement requires recompensation after large deflections[5] In all traces establishment of the whole-cell recording configuration is indicated by arrows Numbers given at the start of each trace correspond to initial cell capacitance values (in pF) as determined by the dial setting of the EPC-7 amplifier (List Electronic, Darmstadt) Average capacitance values were 5 9±0 3 pF (mean±s e m, $n=25$), series resistance values, as read from the EPC-7 settings, were 3 9±0 5 MΩ *a*, To stimulate secretion a pipette filling solution of the following composition was used (mM) K glutamate 135, NaCl 20, $MgCl_2$ 4, ATP 0 5, EGTA 10, $CaCl_2$ 9 (free Ca^{2+} 1 μM), HEPES 10 (*p*H 7 2) The bath solution contained (mM) NaCl 140, KCl 2 8, $MgCl_2$ 2, $CaCl_2$ 2, HEPES 10 (*p*H 7 2) The cell underwent the pretreatments described in *b* except that toxin was omitted from the pipette when 'loading' the cell *b*, The cell was loaded with the toxin in the whole-cell configuration for 3 min and incubated for 1 h at 37 °C Botulinum toxin ($LD_{50}=8$ ng kg^{-1}, mouse s c) was used at a concentration of 50 μg ml^{-1} in a pipette filling solution containing (mM) K glutamate 135, NaCl 20, $MgCl_2$ 4, EGTA 1, HEPES 10 (*p*H 7 2) Both the procedure of loading and the actual test for the secretory response were carried out at 30 °C *c*, Cells were pretreated, incubated and challenged as in *b* except when loading the cells 50 μg ml^{-1} tetanus toxin ($LD_{50}=3$ ng kg^{-1}, mouse s c) was present in the electrode filling solution Vertical scale bar, 0 2 pF, horizontal scale bar, 1 min

capacitance, followed by a phase in which no major alteration was seen (Fig 1*b*) Cells preloaded using pipettes containing no toxin or denatured (boiled) toxins showed a normal secretory response The rates of release resulting from an elevation of the intracellular Ca^{2+} of control and toxin-treated cells are shown in Fig 2

Both secretion and tetanus toxin effects are temperature dependent Lowering the temperature slows, and can even prevent, the inhibitory effects of tetanus toxin at nerve terminals[10] We therefore carried out experiments at different temperatures Whereas secretion at 30 °C proceeded at an average rate of 19 7% per min (see Fig 2), at 20 °C it was reduced to 7 5 ± 1 4% per min (mean ± s e m, $n=6$) At 20 °C the release rate of cells pretreated with tetanus toxin (5 7 ± 1 5% per min, mean ± s e m, $n=11$) was not significantly different from that of control cells This finding clearly indicates that the temperature-dependent step in the action of tetanus toxin is subsequent to binding and internalization Combined with the data obtained using boiled toxins, these results strongly support the conclusion that the inhibitory actions of tetanus and botulinum A toxin on the release mechanism are highly specific and not simply due to the intrusion of a protein of high relative molecular mass (M_r) into the cell

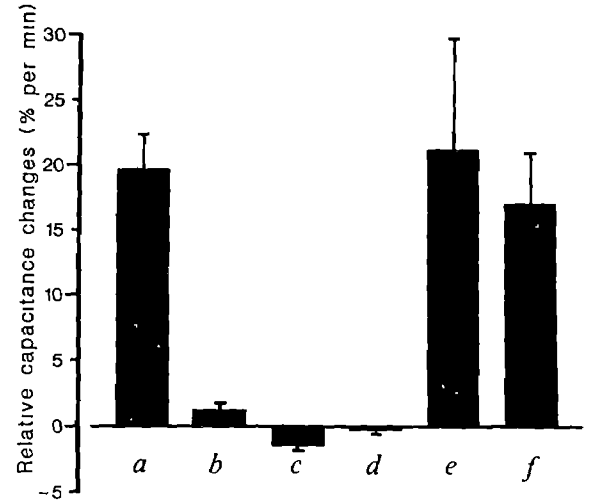

Fig 2 Effects of clostridial toxins on secretion from bovine adrenal medullary cells *a*, Control (mean ± s e m of 14 cells), *b*, botulinum toxin A (10 cells), *c*, tetanus toxin (5 cells), *d*, fragment B (7 cells), *e*, fragment C (4 cells), *f*, denatured tetanus toxin (3 cells) The measure of release chosen was the relative capacitance increase (% of the initial value) per unit time (min) Care was taken to assure relatively uniform cell sizes so that differences in initial capacitance values for each set of experiments were small To determine the release rates capacitance values were measured 2–4 min after transition from cell-attached to whole-cell configuration which usually corresponded to the time in which the capacitance increase was linear (see Fig 1*a* and *e*)

We used the same system to test for intracellular effects of fragments B and C of tetanus toxin Fragment C is a part of the toxin's heavy chain of M_r 50,000 which is thought to mediate binding of the toxin to cell membranes[11,12] Fragment B consists of the light chain covalently linked to the remaining part of the heavy chain (M_r 100,000) These fragments are obtained by enzymatic treatment with papain, and are non-toxic at doses of 10 mg kg^{-1} when injected into mice (the LD_{50} for tetanus toxin is 3 ng kg^{-1}, mouse subcutaneous (s c)[13] Fragment C did not inhibit the responses of chromaffin cells to increased intracellular Ca^{2+} levels (Figs 1*e* and 2), but fragment B effectively suppressed the secretory response (see Figs 1*d* and 2), suggesting that this fragment bears the active site for blocking exocytosis We have thus shown that a fragment of tetanus toxin that is otherwise non-toxic is able to block secretion

It is not known whether fragmentation of the toxin into B and C occurs fortuitiously or whether it is integral to the inhibitory actions of tetanus toxin It appears that some fragmentation occurs *in vivo*, but most of the toxin extracted from the spinal cord (the destination of toxin after uptake into motor nerve terminals and retrograde transport) is indistinguishable from native toxin[14] This suggests that the proposed uptake mechanism of clostridial neurotoxins[2] (drawn by analogy with diptheria toxin and Semliki Forest virus) by receptor-mediated endocytosis followed by expulsion of the toxin's light chain through a 'channel' formed by the toxin's heavy chain into the cytoplasm may not apply From our method of toxin administration it is clear that, even if this described uptake mechanism is used, any specific structural changes occurring during uptake are not absolutely required for the actions of the toxins If changes that are required for activity occur, our results suggest that they are more likely to happen within the cytoplasm

These results support the hypothesis that tetanus and botulinum A toxin act beyond the rise of intracellular Ca^{2+}

concentration, interfering with an as yet unknown step late in the chain of events leading to exocytosis. Our data show that this crucial step is not restricted to the release process from nerve terminals, but may be quite generally associated with vesicular release. Clostridial neurotoxins may serve as valuable tools in studying late steps in exocytosis. The whole-cell recording technique combined with capacitance measurement is useful because it allows the toxins to reach their site of action directly in cells which lack the prerequisite membrane binding and internalization features and allows tests of fragments that are not normally internalized. Experiments using smaller fragments may allow the characterization of a 'minimal toxin' small enough to be introduced into high-voltage[15] or drug-permeabilized[16,17] cells.

We thank Mr U. Weller and Professor E. Habermann for supplying purified fragments B and C. Tetanus toxin was from the Behringwerke (Marburg, FRG), botulinum toxin type A was a gift from Dr Schantz (Food Research Institute, Madison). We also thank Dr S. DeRiemer for valuable comments on the manuscript. This work was supported by the Deutsche Forschungsgemeinschaft (SFB 47).

The essential light chains constitute part of the active site of smooth muscle myosin

Myosin, a major contractile protein, characteristically possesses a long coiled-coil α-helical tail and two heads. Each head contains both an actin binding site and an ATPase site and is formed from the NH_2-terminal half of one of the two heavy chains (relative molecular mass, M_r, 200,000) and a pair of light chains; the so-called regulatory and essential light chains of approximately M_r 20,000 each. Recently we have identified[1] Trp 130 of the myosin heavy chain from rabbit skeletal muscle as an active-site amino-acid residue after labelling with a new photoaffinity analogue of ADP, N-(4-azido-2-nitrophenyl)-2-aminoethyl diphosphate (NANDP)[2]. Nonspecific labelling was eliminated by first trapping NANDP at the active site with thiol crosslinking agents[3]. Exclusive labelling of the heavy chains with no labelling of the light chains agreed with previous findings[4,5] that the heavy chains alone contain the actin-activated Mg-ATPase activity of rabbit skeletal myosin. Here we report similar photolabelling experiments with smooth muscle myosin (chicken gizzard) in which ^{3}H-NANDP is trapped at the active site with vanadate[6] and which show that both the heavy chains and the essential light chains are labelled. The results indicate that both chains contribute to the ATP binding site and represent the first direct evidence for participation of the essential light chains in the active site of any type of myosin.

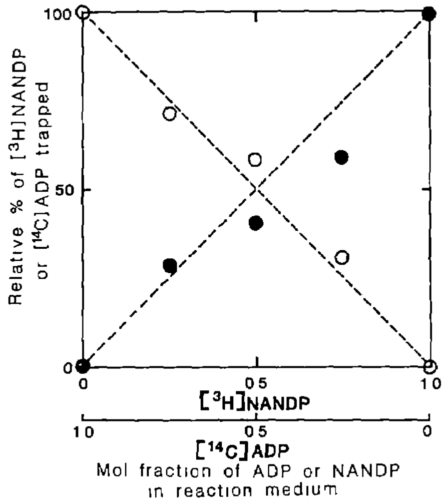

Fig. 1 The relative loss of Ca^{2+} and K^+-EDTA ATPase activities of gizzard myosin as a function of vanadate-trapped [^{3}H]NANDP. Gizzard myosin (4 mg ml^{-1}) in 0.5 M KCl, 2.0 mM $MgCl_2$, 20 mM Tris-Cl, pH 8.0, was incubated with 0.7 mM vanadate and varying concentrations of [^{3}H]NANDP[1,2] for 2 h at 0 °C. Aliquots (0.9 ml) were passed over Sephadex G-25 (PD-10) columns to remove vanadate and untrapped [^{3}H]NANDP. The peak containing myosin-[^{3}H]NANDP-vanadate was assayed for protein (biuret method) and for Ca^{2+} (○) and K^+-EDTA (●) ATPase activities[18]. The [^{3}H]NANDP content was determined by scintillation counting. Actin-free gizzard myosin was prepared from fresh chicken gizzards essentially by the procedure of Ebashi[30] and was in the dephosphorylated form. In addition, all experiments were performed at high ionic strength where all the myosin molecules are in the 6S unfolded state[16]. Vanadate solutions were prepared and analysed according to Goodno[31].

It is of primary importance in photoaffinity labelling studies to eliminate nonspecific labelling. The discoveries that nucleotides and nucleotide analogues could be trapped in the active site of myosin either by crosslinking two reactive thiols, SH_1 and SH_2 (refs 3, 7) or by forming a stable nucleotide complex with vanadate[6] have given highly effective ways to achieve specific photolabelling. Both approaches lead to an ~10^4 decrease in the off-rate of bound nucleotide and give complexes with lifetimes of several days at 0 °C. It is likely that both types of trapping yield quite similar active-site structures since we have found that binding of NANDP can be stabilized at the active site of cardiac myosin by either method (Y.O. and R.G.Y., manuscript in preparation). Photolysis in each case resulted in 50–60% covalent photolabelling of a heavy-chain peptide which was almost identical in sequence to that obtained from rabbit skeletal myosin[1]. Similar studies with other ATP photoaffinity analogues all indicate that heavy chains of skeletal myosin and not light chains are modified[7,8]. Earlier studies by Szilagyi *et al*[9] with an analogue containing a nitroarylazide group on the ribose ring of ATP also photolabelled predominantly the heavy chains although a small amount of labelling on the light chains could not be ruled out. These studies did not, however, utilize either of the two trapping methods mentioned above.

It was of interest to extend our studies to smooth muscle myosin because these molecules, unlike myosins from skeletal and cardiac muscles, exhibit myosin-linked regulation of contraction[10,11]. In addition, gizzard myosin is known to undergo

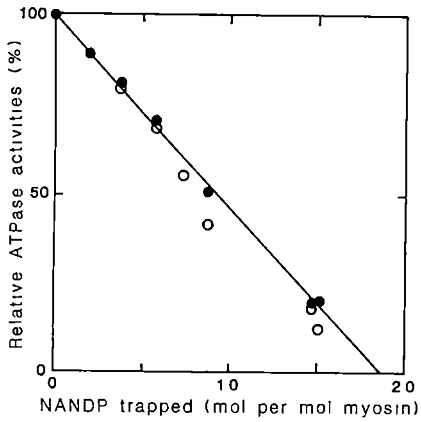

Fig 2 Competitive trapping of [^{14}C]ADP (O) or [^{3}H]NANDP (●) on gizzard myosin by use of the vanadate ion Myosin (4 mg ml^{-1}) in 0 5 M KCl, 2 0 mM MgCl$_2$, 20 mM Tris-Cl, *p*H 8 0, was incubated with 1 mM vanadate and varying ratios of [^{14}C]ADP (Amersham) to [^{3}H]NANDP (total concentration of ADP plus NANDP=0 1 mM) for 2 h at 0 °C The myosin-[^{14}C]ADP (or [^{3}H]NANDP)-vanadate complexes were purified and analysed as described in Fig 1 The maximal amount of trapping under these conditions was 1 34 mol [^{3}H]NANDP per mol myosin and 1 42 mol [^{14}C]ADP per mol myosin

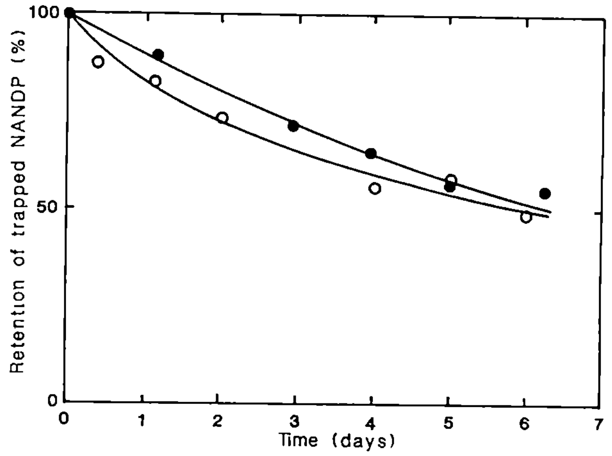

Fig 3 Relative stability of [^{3}H]NANDP-vanadate complexes of gizzard (O) and skeletal (●) myosins The vanadate-[^{3}H]NANDP complexes of gizzard and skeletal myosin were prepared and purified as described in Fig 1 and stored at 0 °C At appropriate times, 0 1-ml aliquots were passed over PD-10 columns (Pharmacia) and analysed for radioactivity and protein concentration[1,18]

large changes in conformation as a function of phosphorylation of the regulatory light chain (LC$_{20}$) (refs 12–14), the binding of Mg-ATP[15], or changes in ionic strength[16,17] In particular, it seemed possible that specific photoprobes could reveal changes in the composition of the active site as a function of these induced conformational changes Moreover, earlier studies using modified gizzard myosin[18] had indicated a close connection between ATP cleavage and changes in a fluorescently-labelled essential light chain, suggesting that essential light chains (LC$_{17}$) were closely linked to the active site We trapped [^{3}H]NANDP on gizzard myosin with a vanadate ion in a manner similar to that described by Goodno for ADP on skeletal myosin[6] In this work, as shown in Fig 1, vanadate stabilized the binding of [^{3}H]NANDP to the active site of gizzard myosin as judged by the parallel loss of both the Ca^{2+}- and K^{+}-EDTA ATPase activities and by the nearly stoichiometric trapping of [^{3}H]NANDP to each head

Competitive vanadate trapping experiments were done with [^{14}C]ADP and [^{3}H]NANDP to verify further that NANDP was binding at the active site Figure 2 shows that as the mol fraction of [^{14}C]ADP was increased relative to the mol fraction of [^{3}H]NANDP, more [^{14}C]ADP was trapped but that the total amount of diphosphate compounds trapped remained constant These results indicate that [^{3}H]NANDP and [^{14}C]ADP bind with comparable affinities to a single type of site and that they compete effectively with each other for stable binding to gizzard myosin

The stability of vanadate trapped [^{3}H]NANDP on gizzard myosin was of considerable interest since specific photoincorporation of NANDP into skeletal myosin has been shown to require previous trapping of some type[1,2] As Fig 3 illustrates, both the gizzard myosin and the skeletal myosin-[^{3}H]NANDP-vanadate complexes show essentially identical long-term stabilities In both cases the half-life at 0 °C was greater than 5 days indicating that leakage of [^{3}H]NANDP from the active site would be negligible during the short time required for purification and photolysis of the trapped complex It should be noted that care was taken to remove traces of actin from gizzard myosin and to keep the temperature near 0 °C Both factors, F-actin and elevated temperatures, are known to destabilize nucleotides trapped at the active site of skeletal myosin[7,19]

The gizzard myosin-[^{3}H]NANDP-vanadate complex purified by gel filtration was photolysed as described in Fig 4 Approximately 0 20 mol per mol active site or 30% of the trapped [^{3}H]NANDP (0 68 mol per mol active site) was found to be attached covalently after 40 min of photolysis It was found to be important in the photolabelling to use irradiation above 400 nm as ultraviolet light caused a photochemical reaction of the trapped vanadate with myosin which in turn allowed [^{3}H]NANDP (or in other experiments [^{3}H]ADP) to leak out of the active site (J G , R G Y and Y O , unpublished results) In control experiments using the conditions in Fig 4, less than 2% of either [^{3}H]NANDP or [^{3}H]ADP trapped with vanadate on gizzard myosin was lost in 40 min of irradiation Complete resolution of the heavy chains from the two light chains, LC$_{20}$ (regulatory) and LC$_{17}$ (essential), was accomplished using high-speed gel filtration on TSK-SW columns in the presence of SDS[20] Surprisingly, as Fig 4 illustrates, some 20% of the photoincorporated [^{3}H]NANDP was associated with LC$_{17}$, with the remainder of the labelling occurring with the heavy chains The LC$_{20}$ chains were not labelled These results suggest that parts of both LC$_{17}$ and the heavy chain combine to form the purine-binding site for ATP Such a finding is reminiscent of the structure of the immunoglobulin G molecule, in which parts of both the heavy chains and the light chains function to form the antigen binding site[21] For IgG, as appears to be the case here, affinity labels gave the first indication that both chains were necessary to form the complete binding site[22,23]

The validity of the interpretation of our results is supported further by the remarkable similarity between NANTP and ATP in their ability to support tension development and relaxation of chemically skinned muscle fibres from all three major types of muscle (R Bridenbaugh, K Nakamaye, G Kerrick and R Y, in preparation) In addition, support of effective tension development in smooth muscle by NANTP required previous thiophosphorylation[24] of LC$_{20}$ because NANTP was not an effective substrate for myosin light-chain kinase These results are clear evidence that NANTP and, by analogy, NANDP, binds to the active site of gizzard myosin in a manner similar if not identical to ATP

The marked difference in the labelling pattern observed for smooth muscle myosin compared with that seen with striated muscle myosins is surprising It is most likely that this difference reflects variations in the heavy-chain sequences because the sequences of the essential light chains from chicken gizzard, heart and skeletal muscle are all highly homologous[25] Currently, little is known about the sequence of smooth muscle myosin

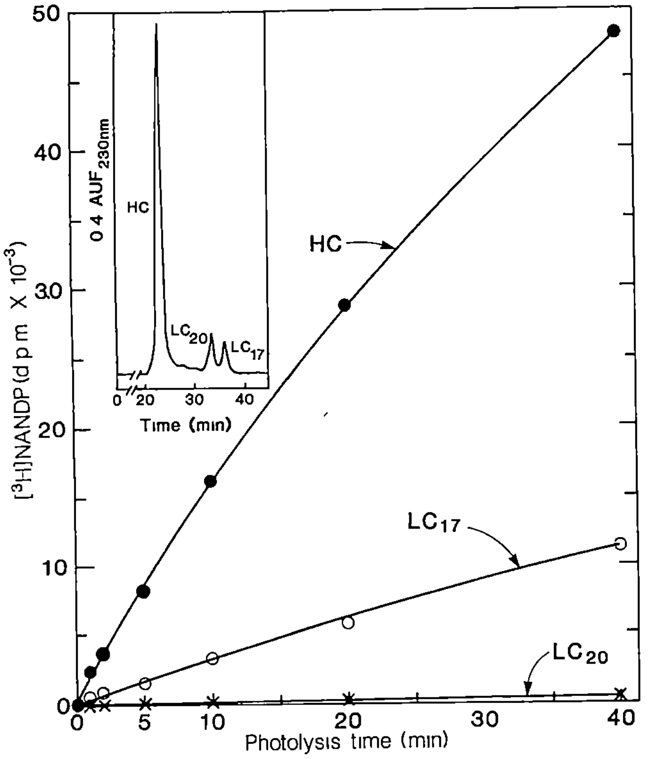

Fig 4 The subunit location of [^{3}H]NANDP photoincorporated into gizzard myosin The gizzard myosin-[^{3}H]NANDP-vanadate complex was prepared essentially as described in Fig 1 except trapping was done overnight using 1 mM Na vanadate, 25 μM [^{3}H]NANDP and 3 7 mg ml^{-1} gizzard myosin The Sephadex G-25 purified complex (10 ml) was irradiated in a 6 cm i d Petri dish at 0 °C with a Ushio (100 W) high-pressure mercury lamp The Petri dish was encased in aluminium foil and the top covered with a glass filter (L-42, Toshiba) to remove irradiation below 400 nm At appropriate irradiation times, samples were taken from the Petri dish, cold trichloroacetic acid added to 5% and the protein precipitate collected by centrifugation The precipitate was dissolved in Tris buffer and SDS (20% solution) added to 0 2% The solution was heated at 100 °C for 3 min, classified by centrifugation and 100 μl of the supernatant passed over serially linked TSK G4000SW and TSK G3000SW columns (7 5 mm × 60 cm each, Toyo Soda) using Beckman-Altex pumps at 100 p s i, flow rate = 1 ml per min All three myosin polypeptides were well resolved (see inset) with the peak of the heavy chain (HC) eluting at 23 min, LC_{20} at 33 min and LC_{17} at 36 min The counts were normalized at each time point to 1 4 mg of myosin (~6 0 nmol of active sites) The distribution of radioactivity was 78±4% into HC and 17±2% into LC_{17}

heavy chains It may be only in the case of myosin-linked regulated systems[26–29] that the essential light chains function to provide part of the ATP binding site Experiments to test this suggestion and to test the possible effect of phosphorylation of LC_{20} and the folding of the heavy chain on the subunit labelling pattern of gizzard myosin are currently under way

Convergent and divergent evolution of regulatory sites in eukaryotic phosphorylases

Peter K. Hwang & Robert J. Fletterick

Department of Biochemistry and Biophysics,
University of California, San Francisco, California 94143, USA

The activity of many proteins in eukaryotic cells is regulated by reversible covalent phosphorylation[1]. This regulatory modification is often linked to other allosteric controls within the same protein[2], and such overlapping regulatory mechanisms are best characterized for glycogen phosphorylase (EC 2.4.1.1). Phosphorylases from different organisms or cell types exhibit markedly contrasting regulatory features[3]; this makes the enzyme attractive for studying the evolution of interacting molecular regulatory mechanisms[4,5]. Extensive biochemical and crystallographic studies of rabbit muscle phosphorylase have led to a characterization of five regulatory regions (phosphorylation, glycogen storage, AMP, glucose and purine sites)[6–8]. Here we report the complete primary structure of the yeast *Saccharomyces cerevisiae* glycogen phosphorylase, deduced from the sequence of the cloned gene. Regions that are highly conserved between muscle and yeast enzymes include the active site, the glycogen storage site and possibly the glucose and purine inhibition sites. Partial conservation of the residues involved in AMP-binding suggests a binding site for the yeast enzyme inhibitor, glucose 6-phosphate[9,10]. Other parts of the AMP site and the intersubunit contacts involved in AMP allostery are disrupted in the yeast enzyme by extreme sequence divergence. The poor alignment of amino termini and lack of homology at phosphorylation sites indicate that regulation by reversible phosphorylation evolved independently in yeast and vertebrate phosphorylases.

The yeast phosphorylase gene was isolated from a collection of yeast genomic DNA fragments cloned into plasmid vectors (see Fig 1 legend) An 890-residue amino-acid sequence was deduced from the nucleotide sequence of a 2 7-kilobase (kb) uninterrupted open reading frame We have compared the yeast amino-acid sequence to that of rabbit muscle phosphorylase (Fig 2) The best alignment requires the introduction of 14 insertions or deletions in one sequence relative to the other (Fig 2 legend) Although the alignment of N termini is somewhat arbitrary, as the two sequences differ considerably, the overall similarity between the yeast and muscle protein sequences is quite high The yeast enzyme exhibits 49% amino-acid identity

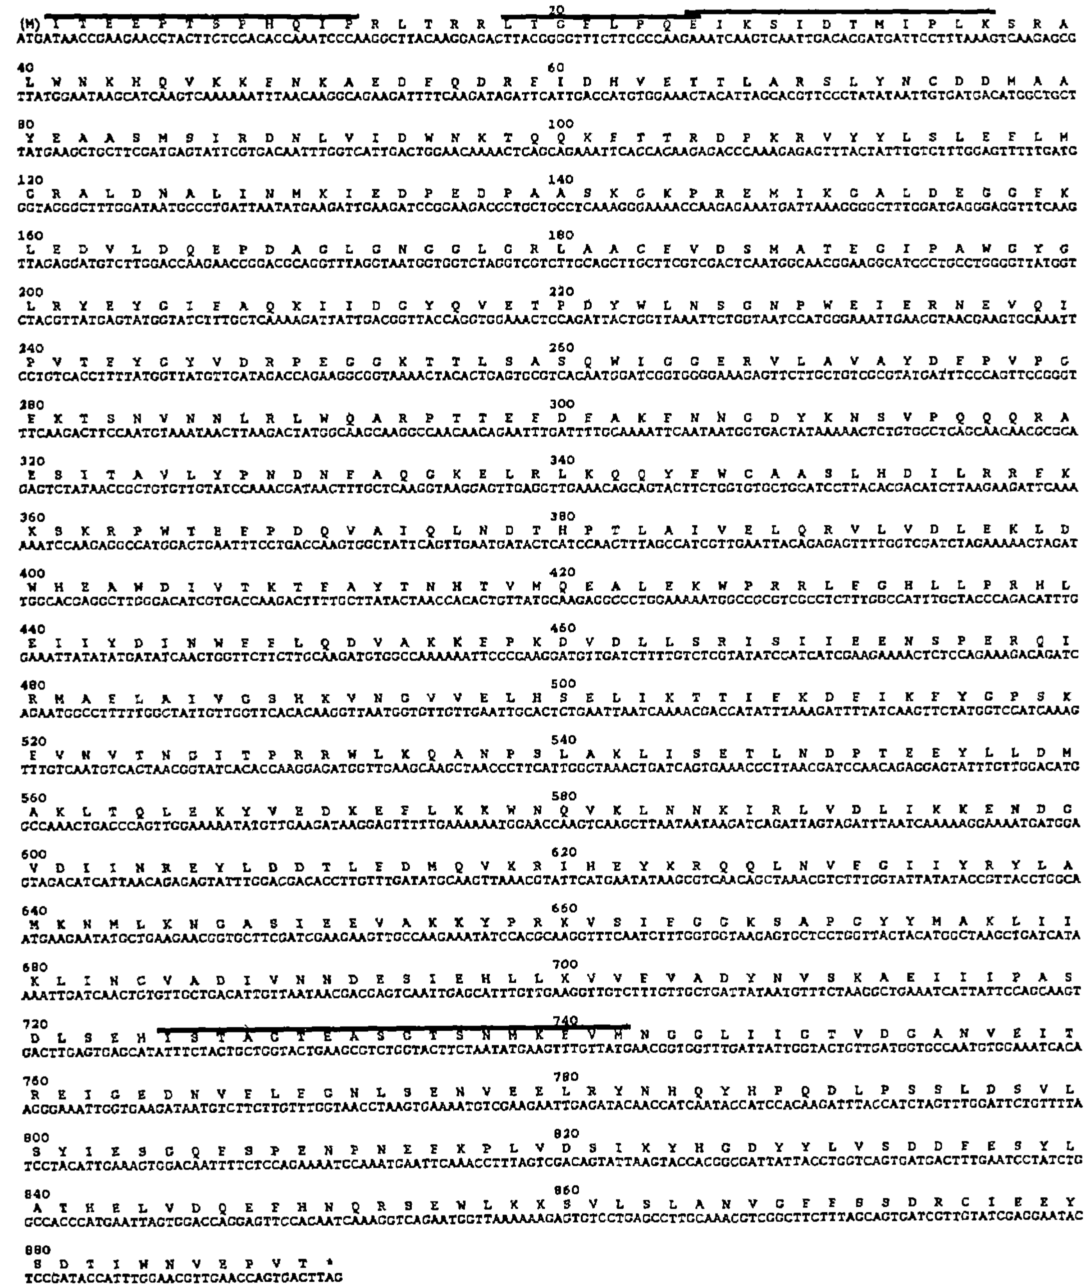

Fig. 1 Nucleotide sequence and derived amino-acid sequence of the glycogen phosphorylase gene in *S. cerevisiae*. The base composition of the DNA sequence is 59.8% A T. The deduced amino-acid composition matches (within 5% for all residues) the previously determined amino-acid analysis[9]. The calculated relative molecular mass of the deduced protein sequence, 102,400 (102,700 if the pyridoxal phosphate is included), agrees with experimentally determined values[9,19]. The predicted C-terminus residue, threonine, also agrees with the result obtained for carboxypeptidase-treated enzyme[19]. Bars, amino-acid sequences previously determined by peptide sequencing: (1) residues 1-12 (E. Schiltz, personal communication), (2) residues 18-25 (ref. 18), (3) residues 25-36 (ref. 19), (4) residues 725-742 (ref. 18).

Methods. The amino-acid sequence of a pyridoxal phosphate-bound peptide of yeast phosphorylase[18] was used to design a mixed oligonucleotide probe (a 32-fold degenerate 18-mer encoding the peptide sequence N-M-K-F-V-M). The probe was radiolabelled by kinase reaction with [γ-^{32}P]ATP and used to screen several yeast genomic DNA libraries contained in plasmid vectors (M. Rose, P. Novick and J. Thomas, personal communication, ref. 30). Hybridizations were carried out in 2×SSC, 0.1% SDS, at 30 °C for 1 h, with $\sim 10^6$ c.p.m. ml^{-1} of probe; washes for 10-15 min were carried out under similar conditions. Pools of plasmids that hybridized to the probe were used to transform *Escherichia coli*. Clones containing putative phosphorylase sequences were subjected to restriction analysis. Fragments containing the oligonucleotide sequence were identified by Southern blot hybridization[31] and sequenced by the M13/dideoxy method[32]. Approximately 92% of the nucleotide sequence was determined in both directions or by multiple sequencing.

to the rabbit muscle enzyme over alignable sequences (403 identical residues at 820 positions). Including conservative replacements at 19% of the aligned positions, the similarity between the yeast and rabbit muscle enzymes is 68%.

Despite the large number of alignment gaps, in most places yeast phosphorylase probably shares a similar tertiary structure with the muscle enzyme. First, all the gaps map to positions on the surface of the rabbit muscle phosphorylase three-dimensional structure and could easily be accommodated in the same structure. Second, most of the non-conservative amino-acid substitutions between the two sequences involve surface residues of the muscle enzyme.

In the catalytic region, all residues involved in cofactor binding or substrate binding are conserved. At the glycogen storage site, only three of the eight residues involved in substrate binding are different in the yeast enzyme, and two of these changes are conservative (Fig. 2).

Two of the five regulatory sites in rabbit muscle phosphorylase bind inhibitors. The enzyme is synergistically inhibited by glucose and purines[11], both of which bind in the active-site cleft formed between the N- and C-terminal domains[12-14]. Glucose binds directly at the active site loop (to Asn 284), which is conserved in the yeast enzyme (Fig. 3). Asp 283, which forms an important part of the loop interaction with Arg 569, is also conserved. Purines bind in a hydrophobic pocket formed by Phe 285 and Tyr 613; these residues are also conserved in the yeast sequence. Conservation of these glucose-binding and purine-binding residues suggests that glucose and purines are involved in the regulation of yeast phosphorylase although this has not previously been investigated.

Fig 2 Comparison of the primary structures of yeast and rabbit muscle phosphorylases The rabbit muscle phosphorylase sequence includes the corrections of Nakano *et al*[33] and has been renumbered accordingly The Dayhoff alignment program[34] was used to obtain the best homology Further adjustment was by computer graphic modelling of the altered yeast side chains on the tertiary structure of the rabbit muscle enzyme (Details of this procedure will be published elsewhere) Gaps (−) have been inserted to maximize similarity Only non-identical residues of rabbit muscle phosphorylase are indicated At the N terminus, yeast phosphorylase is 28 residues longer than the muscle enzyme, at the C terminus, it is shorter by 11 residues There are 12 other sites of insertions/deletions in the yeast sequence relative to muscle Two deletions, of 8 and of 3 residues, are found at positions corresponding to loops in the rabbit muscle enzyme (316–323, 723–725) Of the 10 insertions, 5 involve additions of a single amino acid, preceding positions 438, 474, 735, 767 and 794 of the rabbit enzyme sequence The rest are multiple-residue insertions three residues at position 507, six at 213 and 557, nine at 591 and 13 at 114 Lower case letters, residues of rabbit muscle phosphorylase involved in catalytic or regulatory interactions d, dimer or subunit interface, p, covalent phosphorylation site, a, AMP effector binding site, g, active site (and glucose inhibition), c, caffeine and purine inhibitor binding site, s, glycogen storage site, v, pyridoxal-phosphate cofactor binding site

Muscle glycogen phosphorylase exhibits allosteric activation by AMP, the binding site is well characterized in the three-dimensional structure and is 30 Å from the active site[15] The site can be thought of as three subsites, one each for the phosphoryl, sugar and base moieties of AMP The phosphoryl and sugar subsites also bind phosphate, glucose 1-phosphate and glucose 6-phosphate[16] The positive charges of Arg 242, Arg 309 and Arg 310, which form the pocket for binding the phosphate moiety of AMP in rabbit muscle phosphorylase, are conserved in the yeast sequence and, from model building, appear to form a similar binding pocket In the sugar subsite of muscle phosphorylase, Asp 42 and Gln 71 interact with the ribose portion of AMP, in the yeast enzyme, only Gln 71 is conserved In the base subsite, Tyr 75 forms an important stacking interaction with the adenyl group of AMP, and Asn 44 and Val 45 also make van der Waals' contacts with the adenine, none of these residues is conserved in the yeast enzyme It is unlikely that the activator site of muscle phosphorylase functions in the yeast enzyme by binding AMP, not only because important binding residues are not conserved, but because the protein structure near the sugar and base subsites is probably also altered All the residues mentioned which comprise these subsites lie within the N-terminal 80 amino acids of muscle phosphorylase, a region of little structural homology

A more intricate control of glycogen metabolism is exerted by reversible covalent phosphorylation of phosphorylases Although yeast and muscle phosphorylases interconvert between phosphorylated (active) and dephosphorylated (inactive) forms, many components of the mechanism are known to be different For example, the phosphorylated peptide isolated from the N terminus of rabbit muscle phosphorylase is conserved in vertebrate phosphorylases[17], the phosphorylated peptide in the yeast enzyme, however, does not match this sequence[18] In addition, the specific modifying enzymes of muscle phosphorylase do not act on the yeast enzyme[9] From the poor homology and different N terminus lengths (Fig 2), it is obvious that the substrate sites for the interconverting enzymes are dissimilar The target of phosphorylation in the yeast enzyme is a threonine (residue 19) that appears in the extended N terminus The amino-acid sequence around this residue (Arg-Arg-Leu-Thr) matches the consensus sequence for phosphorylation sites in substrates of cyclic AMP-dependent protein kinase[1], in accordance with the finding that yeast phosphorylase can be phosphorylated by this enzyme[19,20] We cannot identify any homologous element in the

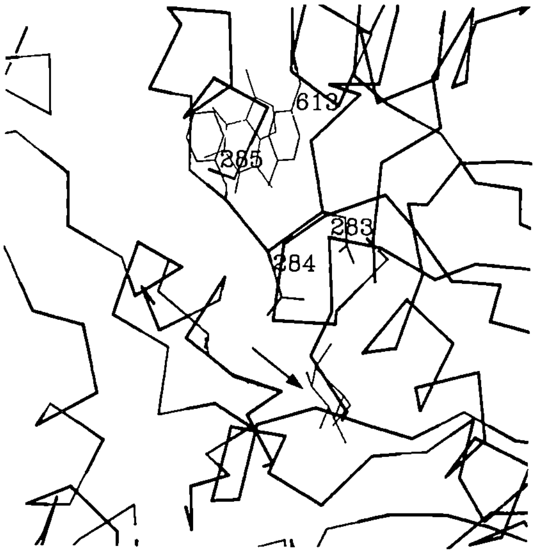

Fig 3 Comparison of the three-dimensional structures of rabbit muscle and yeast phosphorylases at the active-site cleft Darker segments of the α-carbon representation indicate identical or chemically similar residues conserved between the yeast and rabbit muscle enzymes, lighter segments indicate non-conserved residues Predominantly in dark segments, this region appears structurally conserved in the yeast enzyme Arrow, the active site, shown occupied by glucose and with conserved side chains Asp 283 and Asn 284 Side chains Phe 285 and Tyr 613 (thin lines) form the purine inhibition site (shown occupied by caffeine) and are also conserved in the yeast enzyme

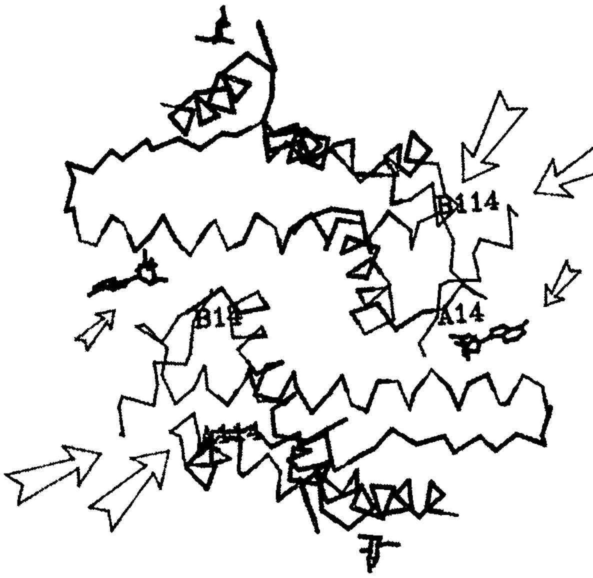

Fig. 4 Comparison of yeast phosphorylase to the three-dimensional structure of the rabbit muscle phosphorylase dimer (active conformation) at the AMP site, subunit interface and serine-14 phosphorylation site Shown are projected α-carbon representations of a similar region in two contacting subunits (chains distinguished by labelling residues A and B) Identical or similar residues between rabbit muscle and yeast enzymes are indicated in darker segments Lighter segments indicate non-conserved positions Many differences occur in this region The phosphorylation site, Ser 14 (positions A14 or B14), lies adjacent to the AMP site, shown occupied by AMP (small arrow) Larger arrows mark position 114, where yeast phosphorylase contains a 13-residue insertion, and the N terminus, where the yeast enzyme contains 28 extra residues

yeast sequence with which the phosphorylation site of muscle phosphorylase (Ser 14) might align In addition, there is no homology between the yeast N-terminal sequence and corresponding regions of other eukaryotic or prokaryotic phosphorylases$^{5,21-25}$

The intersubunit contacts of the rabbit muscle phosphorylase dimer are also significant in the regulatory mechanisms of the enzyme^{6,7} The structural segments that comprise the subunit interface couple the AMP and phosphorylation sites to the active-site region^{6,26} Major differences between muscle and yeast enzymes occur in this region (Fig 4) We have already noted specific alterations at the AMP binding site and the phosphorylation site, and the lack of homology at the N terminus Other residues involved in the intersubunit contact of muscle phosphorylase are indicated in Fig 2, most of these are not conserved in the yeast sequence In addition, there are two major length variations at positions near the dimer interface, at the N terminus, yeast phosphorylase has an extra 28 residues compared with the muscle homologue, and at a position homologous to residue 113 of the muscle enzyme, the yeast enzyme contains an insertion of 13 residues Thus, the subunit interface, as found in rabbit muscle phosphorylase, appears to be altered in the yeast enzyme, implying that intersubunit cooperativity in yeast phosphorylase involves structural components and mechanisms that are distinct from those in the muscle enzyme

Yeast phosphorylase is strongly inhibited by glucose 6-phosphate^{9,10} Although our analysis shows that a functional AMP activator site is disrupted in the yeast enzyme, conservation of the phosphoryl subsite and partial conservation of the sugar subsite suggest that this region serves as the binding site for glucose 6-phosphate This hypothesis is supported by the following evidence Inhibition of yeast phosphorylase by glucose 6-phosphate is non-competitive with respect to both glucose 1-phosphate and glycogen^{9}, implying that the effector binds somewhere other than at the catalytic site Glucose 6-phosphate does bind at the AMP site of inactive (dephosphorylated) muscle phosphorylase and inhibits activation (phosphorylation)^{16,27} Crystallographic studies^{16} have implicated all the conserved residues between yeast and muscle enzymes at the AMP site in the binding of glucose 6-phosphate to rabbit muscle phosphorylase Trp 67, another residue in contact with glucose 6-phosphate in rabbit muscle phosphorylase^{16}, is also conserved in the yeast enzyme

The lack of sequence homology at the N terminus indicates that the phosphorylation sites of yeast and vertebrate phosphorylases did not evolve from a common ancestral regulatory region Palm *et al*^{5} have suggested that a preformed nucleotide sequence encoding a phosphorylatable peptide was fused to a primordial phosphorylase gene in the evolution of vertebrate phosphorylases If true, it seems that a separate gene fusion event generated the phosphorylation site in yeast phosphorylase Of course, the acquisition of a phosphorylation site alone would not have been sufficient for covalent regulation, because allosteric regulation by reversible phosphorylation requires intersubunit interactions that couple phosphorylation to active-site changes The N-terminal sequence divergence that generated different phosphorylation sites in yeast and muscle enzymes also affected development of appropriate intersubunit contacts Although its structure remains to be elucidated, the subunit interface in yeast phosphorylase must differ significantly from that of muscle phosphorylase but still functions analogously, transmitting regulatory responses to the catalytic site Hence, the intersubunit interactions responsible for allosteric transmission in yeast and muscle phosphorylases seem to have arisen by convergent evolution Presumably, the dissimilar N termini also influenced the completion of the coupled allosteric ligand-binding site, enabling development of contrasting regulatory functions, glucose 6-phosphate inhibition in yeast and AMP activation in muscle

Finally, how has the regulatory phosphorylation cascade evolved with time? The phosphorylated and dephosphorylated forms of muscle phosphorylase are interconverted by phosphorylase kinase and phosphorylase phosphatase, specific enzymes that, in turn, are regulated (phosphorylated) by cyclic AMP-dependent protein kinase The phosphorylation site of yeast phosphorylase, however, is recognized by both the cyclic AMP-dependent protein kinase and a specific phosphorylase kinase[19,20], as well as by a general protein phosphatase[28,29] The following evolutionary model is consistent with these observations a phosphorylation site recognized by a general protein kinase (and phosphatase) was initially spliced onto the N terminus of the ancestral enzyme, divergence of this site led to poorer recognition and eventually loss of recognition by the general protein kinase, coevolution of other kinases (and phosphatases) gradually restricted their range of substrates, resulting in specificity for phosphorylase The difference in phosphorylation site specificity between yeast and muscle phosphorylases may reflect how far the regulatory cascades of yeast and vertebrates have evolved in this general path

We thank Drs Michael Stern, Susan Michaelis, Christopher Newgard, Kenichi Nakano and John Burke for helpful advice, discussions and technical assistance Supported by a grant from the NSF (PCM84-20489)

α-Lactalbumin possesses a novel calcium binding loop

D. I. Stuart*, K. R. Acharya*, N. P. C. Walker†‡, S. G. Smith*, M. Lewis*‡ & D. C. Phillips*

Calcium performs a unique role in biology, achieving biological effects through highly specific interactions with and modulation of target proteins[1]. It has been proposed that calcium-modulated proteins possess a characteristic, evolutionarily related, binding fold, known as the EF-hand[2]. The high-resolution X-ray structure of α-lactalbumin reveals a Ca^{2+} binding fold that resembles an EF-hand only superficially and presumably has no evolutionary relationship with it. However, there is clear homology with the corresponding loop in c-type lysozyme (the 'parent' molecule of α-lactalbumin). This study, at 1.7 Å resolution, represents one of the most accurate analyses of a calcium binding protein yet reported.

α-Lactalbumin acts as a specifier protein[3], it comprises some 15% of total protein in human milk[4] and is essential for the production of lactose The attachment of α-lactalbumin to β-galactosyl transferase on the luminal surface of the Golgi membrane results in a complex, lactose synthetase that catalyses the addition of galactose to glucose to produce lactose α-Lactalbumin is a small protein that has about 40% sequence identity with c-type lysozyme, and also a similar intron-exon genetic organization[5], strongly suggesting that the two have diverged from a common ancestor α-Lactalbumin is a calcium metalloprotein[6], the K_{app} in physiological conditions is likely to be of the order of 10^{-6}–10^{-7} M (ref 7), comparable to that observed for the calcium-modulated proteins[1] In addition, Zn^{2+} binding has been observed (K_d 5 μM)[8] The biological role of metal ion binding is unclear If the concentration of free calcium ions in the Golgi lumen is comparable to that in milk (about 3 mM), it would be expected that the Ca^{2+} site would be fully occupied, whereas the occupation of the Zn^{2+} site would be uncertain The first role proposed for the Ca^{2+} binding was to stabilize the protein and protect it from thermal denaturation[6,9], more recently it has been claimed that the pattern of ion binding affects the catalytic properties (notably the V_{max}) of the lactose synthetase complex[8] Calcium binding may also be important in controlling the release of α-lactalbumin from the Golgi membrane, an essential step in inducing lactation[8] It is plausible that these mechanisms allow fine control of lactose synthesis

The second messenger role of Ca^{2+} ions, binding to target proteins and hence inducing a conformational change, is well established Unfortunately, in no case is the precise mechanism of triggering understood in terms of the concomitant conformational changes, although the crystal structure of troponin-C gives some hints[10] In the case of α-lactalbumin, knowing the structure of lysozyme, a close homologue with no marked propensity for binding calcium, it is possible to infer something of the conformational changes induced by the calcium binding by comparison with the structure of the calcium-bound form of α-lactalbumin

Structural studies on crystalline α-lactalbumins have been in progress for a number of years but have been frustrated by various problems[11,12] We have determined the structure of α-lactalbumin from baboon milk Low-resolution isomorphous replacement phases allowed the approximate orientation of the molecule in the unit cell to be determined and confirmed that the structure is broadly similar to lysozyme[13,14] A process of careful refinement (initially of a lysozyme model) against the X-ray observations revealed the detailed structure This work will be reported in detail elsewhere The sequence of the enzyme from baboon milk has not been determined, but preliminary experiments suggested very few differences between the sequences of human and baboon α-lactalbumins (R Greenberg, personal communication) Our present model therefore has few changes from the human α-lactalbumin sequence The *R*-factor[32] of 0 207 (for 10,627 data $>2\sigma(F)$ to a resolution of 1 7 Å) together with the reasonable stereochemistry exhibited by the model (r m s (root mean square) deviation from ideal

covalent bond lengths = 0.03 Å) and the high quality of the electron density map lead us to be confident of our interpretation of the molecular structure. We have placed all the protein atoms and 132 water molecules. We estimate that the coordinates for the parts of the structure that we discuss below are accurate to within a few tenths of an ångstrom unit. The determination of the α-lactalbumin structure represents a notable application of the molecular replacement method as the starting model has only 37% sequence identity with α-lactalbumin and is a distinct enzyme.

When the enzyme is crystallized and no metals added to the crystallization medium, as expected from the binding affinity data, the calcium binding site is occupied. Nucleic acid sequences[15] and revised amino-acid sequences[16] reveal two pairs of strongly conserved aspartic acid residues (82, 83 and 87, 88). This led to the proposal[16], subsequently supported by NMR data[17], that these four residues are concerned in calcium binding. We find that three of these residues are calcium ligands. The Ca^{2+} site is easily identifiable as a persistent feature of our difference Fourier maps which cannot be adequately accounted for by a water molecule. Refinement fully confirms this assignment, the current B-values for the ion and its ligands being about 15 Å^2 and indeed the B-factors for all this region are among the lowest in the molecule. Figure 1 shows the detailed atomic structure around the calcium, which is surrounded by seven ligands, all oxygens, three from the carboxylate groups of aspartyl residues (82, 87 and 88), two carbonyl oxygen atoms (from residues 79 and 84) and two water molecules. The five ligands contributed by the protein come from a rather tight turn akin to a β-turn with an extra residue, Asp 82, acting as a 'spacer' between two helices. We shall subsequently refer to this structure as the 'elbow'. The geometry in small-molecule-Ca^{2+} complexes is variable but generally involves six, seven or eight ligands with a distorted pentagonal bipyramid being the most common configuration in the seven coordinate case (G. Klebe, personal communication). When calcium binds to proteins, the solvent often contributes one or more ligand[18]. In α-lactalbumin the coordination is ideal, forming a slightly distorted pentagonal bipyramid with carbonyl oxygen atoms at the apices while the carboxylate groups and water are arranged with the waters approximately opposed (Fig. 1). The Ca–O distances, ranging from 2.3 Å to 2.5 Å (Table 1), are close to the expected value of 2.4 Å.

The only comparable calcium binding sites described for other proteins (in terms of affinity and topology) are those forming the class of folds known as the EF-hand[2]. Comparison of the α-lactalbumin loop with an EF-hand (see Fig. 2) reveals that although the elbow of α-lactalbumin is a more compact structure (consisting of two fewer residues) there are certain marked similarities, both structures are formed from a loop between almost orthogonal helices and deploy similar types of ligands around the Ca^{2+}. In α-lactalbumin a single Asx turn[19] stabilizes the structure whilst the longer EF-hand uses several of these. Furthermore, in both cases there is a conserved central hydrophobic residue (Ile 85 in α-lactalbumin) which is important in stabilizing the structure as a whole. We can discount the naive hypothesis of an homologous relationship for several reasons. Firstly because the evolutionary history of α-lactalbumin rules out such a scheme. Secondly, the Ca^{2+} coordination observed for the typical EF-hand is considered a distorted octahedron compared with the pentagonal bipyramid of α-lactalbumin. Finally, on searching a database of well-refined structures for related conformations[20], the only structures found that were closely similar to a given EF-hand were other EF-hands. These structures superimpose to better than 1 Å r.m.s. deviation. As there are a large number of unrelated structures that superimpose to within about 2 Å, there is no evidence for significance in the structural similarity with the elbow where the r.m.s. deviation exceeds 2 Å.

Comparing the calcium binding loop in α-lactalbumin with the corresponding structure in hen egg white lysozyme we find, surprisingly, that the conformation of the backbone is essentially unchanged whereas the side chains are radically altered (Fig. 2). The r.m.s. deviation in C_α positions for this loop is 1.2 Å. The differences are largely attributable to movement of the loop away from the body of the molecule in α-lactalbumin compared with lysozyme. If we superimpose the coordinates of the loop alone, we find that they agree with an r.m.s. deviation of 0.6 Å, as close a similarity as that found between the calcium binding loops of the EF-hand proteins[18] and indeed as that between human and hen lysozyme. Further evidence of the high degree of similarity comes from an analysis of the water structure around this loop in α-lactalbumin and lysozyme. There is a network of three water molecules in hen egg white lysozyme that corresponds to two water molecules and the calcium ion in α-lactalbumin[21]. The fold at the elbow seems to be unusual, no other loops superimpose well. The best fit (with rhodanese, residue 278 onwards) has an r.m.s. deviation of 1.8 Å and many others are about as good. Hence, although this loop is a region of considerable similarity in structure, there are important differences in sequence (Table 2).

Table 1 The calcium ligands

79	Lys	Carbonyl	O	2.3
82	Asp	Carboxylate	OD1	2.4
84	Asp	Carbonyl	O	2.3
87	Asp	Carboxylate	OD1	2.3
88	Asp	Carboxylate	OD1	2.4
		Water	O	2.4
		Water	O	2.5

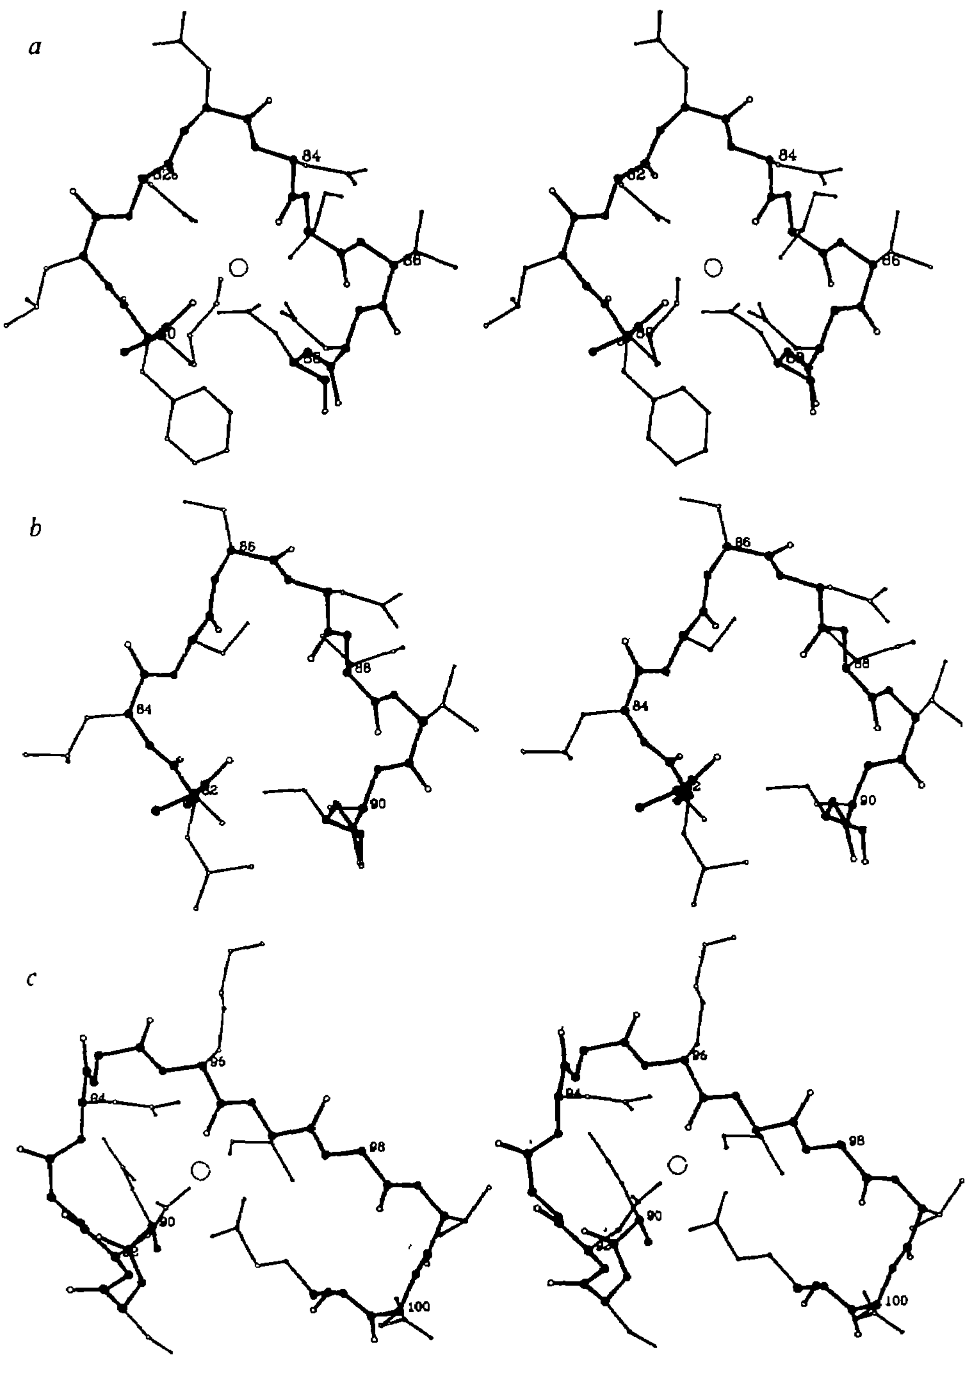

Fig. 2 Rotationally aligned structures of *a*, residues 79-88 in α-lactalbumin, *b*, residues 82-91 in hen lysozyme, *c*, residues 90-101 in carp parvalbumin, the EF-hand, data set F6A in the protein data bank[29] The central, enveloped atom in *a* and *c* is calcium The superimpositions were performed using a computer program[30] drawing on the ideas of Rossmann and Argos[31] The optimal rotation matrices were determined on the basis of the C_α coordinates of the residues in the loops (all 10 residues of the α-lactalbumin loop were matched with parvalbumin residues to give an r m s deviation of 2 5 Å)

The above analysis refers to the hen lysozyme structure We have also looked at human lysozyme[22] where the three aspartates of α-lactalbumin that contribute carboxylate ligands correspond to Gln 86, Asp 91 and Ala 92 Asp 91 is rotated by ~90° about $\chi 1$ (compared to α-lactalbumin), to bring the charged atoms into solution, whereas the ε-nitrogen of Gln 86 is at the position of a water ligand of Ca^{2+} in α-lactalbumin It seems therefore that human lysozyme contains a partially formed calcium binding site without a destabilization of protein structure Ala 92 is rather internal and its conversion to an Asp in the absence of some compensating charge or change in conformation would be expected to destabilize the protein A survey of lysozyme sequences reveals that the sequence of horse milk lysozyme[23] shows the full complement of the three aspartate residues that form Ca^{2+} ligands in α-lactalbumin If this sequence is correct, it raises the intriguing possibility that horse milk lysozyme might bind calcium

It has been suggested that the entropic effects of calcium binding are more unfavourable in α-lactalbumin than the EF-hand proteins[24] At first sight this is puzzling, the *B*-values for this loop in lysozyme are low[21], and therefore entropic effects due to ordering of the loop on calcium binding should be small Furthermore the rigidity of the calcium binding loop in α-lactalbumin is responsible for the discrimination the site shows between Ca^{2+} and Mg^{2+} (the K_ds differ by approximately 10^5), the loop being unable to collapse around the smaller Mg^{2+} ion Nevertheless, uncompensated negative charges should destabilize the observed lysozyme conformation, so what conformational changes are likely? The results of the database search do not indicate any closely related folds that could be formed by rearrangement of the loop but a variety of structures are observed that differ by about 2 Å No quantitative evidence is available on the Ca^{2+}-induced conformational changes[25] but a possible mode of action could involve a relatively small conformational change at the Ca^{2+} binding site, perhaps triggering rigid body movements of secondary structural units as has been described for other structural transitions[26]

The observations on the structure of the calcium binding

Table 2 Amino-acid sequences at the α-lactalbumin elbow

* Residues that contribute a side-chain calcium ligand, + residues that contribute a carbonyl oxygen ligand

elbow are relevant to protein evolution The divergence of α-lactalbumin from lysozyme involves the formation of a novel enzyme system, and seems to be related to the formation of an extremely well developed Ca^{2+} binding ability, a surprising innovation We would argue against an alternative evolutionary interpretation, that an ancestral lysozyme possessed Ca^{2+} binding activity and the current lysozyme structure retains a 'memory' of this, because the proposed serial homologues (phage, goose and hen type lysozymes[27]) do not possess this loop as a common feature It is an interesting coincidence, however, that the loop of phage lysozyme once proposed as a calcium binding loop is probably homologous to a region fairly close to the elbow in α-lactalbumin[27,28] Clearly the evolution of a novel functional property of the α-lactalbumin molecule has not come about through exon shuffling or any sophisticated structural modifications It seems instead to be a structurally localized property that arose principally through simple amino-acid substitutions at three positions to produce a calcium binding site of exquisite specificity While other cases of divergence of structures to fulfil radically different functions are known (for example, the various functionally diverse immunoglobulin domains), here the process is so recent that we feel that we have almost caught evolution *flagrante delicto* Naturally α-lactalbumin may lend support to the rather simplistic approach to protein engineering that considers function to be a local property Such a hypothesis can be tested easily in this case by investigating the effects of mutagenic modification of the lysozyme loop in an attempt to produce a calcium binding site (as may have already been accomplished naturally in the horse milk lysozyme) We would be pleased if our observations stimulate such studies and studies on the biological significance of calcium binding to the lactose synthetase Although the lactose synthetase complex is not cytosolic, it is interesting to see essentially intracellular calcium binding at a site with no homology to the EF-hand At any event it is encouraging to see nature innovating rather than restricting itself to spare-functional-part protein design

DNA fragments that show retarded electrophoretic mobility through polyacrylamide gels have been found in both prokaryotes and eukaryotes[1-7]. In the case of kinetoplast DNA, evidence has been presented that the DNA is curved or 'bent'[8,9]. Bent DNA has previously been found at the λ and simian virus 40 (SV40) DNA replication origins[6,7]. Here we show the existence of bent DNA at a yeast autonomously replicating sequence (ARS1), a putative replication origin. The bent DNA has been localized to a 40–55 base pair (bp) segment and contains six $(A)_{3-5}$ stretches (that is, six poly(A) stretches, three to five nucleotides in length) phased approximately every 10.5 bp. This region contains a DNA binding site for a yeast protein factor. This site lies at the 3′ end of the *TRP1* gene, in a region devoid of nucleosomes, and is positioned 80 bp away from the ARS consensus sequence; removal of this region impairs ARS function *in vivo*. The bent DNA may be involved in transcription termination or the prevention of nucleosome assembly in this region.

Yeast ARS sequences have properties expected of origins of replication they allow the autonomous replication of sequences to which they are attached, occur at a frequency expected of chromosomal origins, replicate once per cell cycle using genes responsible for chromosomal replication and act as origins of replication *in vitro* (see ref 10 for review) Electron microscopic data for ribosomal DNA and 2μ DNA has mapped nascent replication bubbles near ARS elements suggesting that ARSs act as replication origins *in vivo*[11,12]

The structure of ARS1, which is near the 3′ end of the yeast *TRP1* gene, is shown in Fig 1 There are three elements that comprise ARS1, domains A, B and C Domain A is an 11-bp consensus sequence found at most other ARS sequences[13,14] Mutations in this sequence at ARS1 or the ARS at the HO locus obliterate ARS function *in vivo*[13,15,16] Domains B and C flank ARS1 and are important for its function[16-18], mutations in either

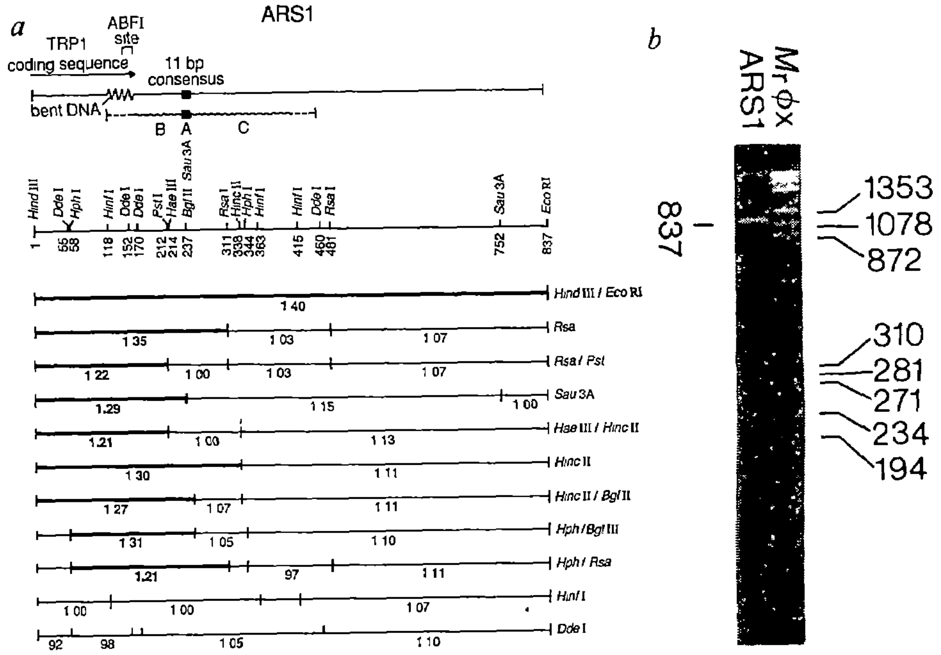

Fig. 1 *a*, Features of yeast ARS1; *b*, mobility of ARS1 restriction fragments on a 10% polyacrylamide gel. A (box), B and C (〰 lines) are indicated. The broken lines indicate the degree of uncertainty of the extent of domains B and C. The *Hin*dIII/*Eco*RI ARS1 fragment was digested with the various restriction enzymes indicated, ethanol-precipitated and the electrophoretic mobilities of the fragments measured in a 10% polyacrylamide gel using 50 mM Tris base, 50 mM boric acid, 1 mM EDTA buffer[20]. Electrophoresis was at 2.9 V cm^{-1} for 16 h at 24.5 °C. Correct assignment of the DNA bands was determined by digestion with a second enzyme. Beneath the fragments is indicated the *k* value = expected distance migrated/observed migration distance. Fragments where $k > 1.20$ are indicated in bold type (not determined for fragments less than 60 bp). *b*, Migration of the 837 bp (determined from DNA sequence[23]) *Hin*dIII/*Eco*RI ARS1 restriction fragment in a 10% polyacrylamide gel. 837 indicates the position of the 837-bp ARS1 fragment. Sizes of ΦX174 *Hae*III marker fragments are given. The 281-bp fragment of ΦX174 migrates more slowly than expected. Other standards used are λ *Bst*EII markers and pBR322 *Hin*fI markers (not shown).

region reduce, but do not abolish, ARS function *in vivo*. Domain B begins very close to the 3′ end of the *TRP1* gene and may overlap it. A protein factor called ABFI (ARS binding factor I) that has been partially purified from yeast extracts,[20] binds in this region. The roles of the different ARS domains A, B and C, and of ABFI are unknown.

Because bent DNA has been found at bacteriophage and viral DNA replication origins[6,7], we tested for unusual DNA conformational features in the ARS1 region by subjecting restriction fragments of ARS1 DNA to electrophoresis in 10% polyacrylamide gels and identifying DNA fragments that exhibited unusually retarded mobility[19,21,22]. The mobilities were compared to 'normal' DNA fragments derived from pBR322, ΦX174 and λ DNAs (see Fig. 1 legend). Several DNA fragments were found that migrate 20–40% more slowly than predicted from the known DNA sequence[23] at 24.5 °C (Fig. 1). For example, an 837-bp fragment migrates to a position expected of a 1,170-bp fragment, 40% more slowly than anticipated. Using the method of Diekmann and Wang[19], several restriction fragments spanning the ARS1 region were tested for abnormal electrophoretic mobility and their *k* values determined (*k* = expected distance migrated/observed distance migrated for the DNA fragments). All DNA fragments that contain the 150-bp region between the *Hph*I and *Pst*I sites are found to have *k* values > 1.20. DNA fragments generated by cleaving the DNA with *Hin*fI and *Dde*I that cut within this 150-bp segment do not show abnormal mobility. Data presented below demonstrate that the *Hin*fI (118) and *Dde*I (152, 170) sites bracket a region which has properties characteristic of bent DNA. It is clear that there is a strong correlation between the position of the 118–170 *Hin*fI/*Dde*I region within a fragment and the observed *k* value. It has been noted that when the bent sequence is near the end of a fragment, the effect on retarded mobility is diminished[21]. Similar results were obtained after the digested ARS1 DNA was extracted with phenol or treated with proteinase K (data not shown). Thus reduced mobility does not appear to be due to association with proteins.

The abnormal DNA region was further localized by deletion analysis. A series of five deletions beginning at the *Hin*dIII site and extending increasing distances towards ARS1 were constructed (Fig. 2). These are called Δ108–Δ197, the numbers refer to the number of base pairs deleted. Restriction fragments of plasmids containing these deletions were generated by cleaving at sites located 150–200 bp outside the deletion regions in such a way that the putative bend is approximately in the centre of the fragment. The mobility and *k* values of these DNA fragments are shown in Fig. 2. Both the wild-type (wt) and Δ108 DNA fragments migrate more slowly than expected (31 and 32% more slowly, respectively). Δ149 (which differs from Δ108 by 41 bp) migrates normally. Thus at least some of the DNA that confers abnormal mobility lies between 108–149 bp on the map in Fig. 1.

Bent DNA tends to migrate more 'normally' at higher temperatures[19,22]. ARS1 DNA fragments from the deletion plasmids were analysed as above except that the electrophoresis was performed at 38 °C instead of 25 °C. As shown in Fig. 2, the wild-type and Δ108 fragments migrated faster at the higher temperature (lower *k* values). Relative mobilities of fragments lacking the 108–149 region were not affected by temperature. Thus, the effect of temperature on abnormal migration is consistent with the presence of bent DNA. Abnormal migration cannot be due to simple denaturation of DNA sequences, which would have the opposite effect with temperature. Inspection of the DNA sequence in the 108–149 region reveals the presence of six A_{3-5} stretches phased approximately every 10.5 bp (Fig. 3). This feature is characteristic of the bent DNA observed in kinetoplast DNA and λ replication origin[6,8,21]. It has been shown[22] that bending occurs at the 3′ junctions of A tracts, and is maximized when the 3′ A junctions are phased approximately every 10 bp.

Interestingly, DNA footprint analysis with partially purified yeast extracts demonstrates that a protein factor (ABFI) specifically binds to this region at residues 139–155 (Fig. 3). So far, five different binding sites for this factor have been identified in yeast DNA near ARS elements[24]. The binding site at ARS1 contains an $(A)_5$ stretch directly in its centre and other binding sites contain $(A)_{3-4}$ stretches. The bent conformation of the DNA at ARS1 may affect the affinity with which this factor binds DNA, similarly to SV40 T antigen where the nucleotides contacted by T antigen flank a DNA bend that is critical for binding[7].

To determine whether the bent DNA region is important for ARS1 function *in vivo*, the effect of the five deletions shown in Fig. 2 on ARS activity was assayed. Each ARS fragment was

Fig 2 Deletion analysis through the bent DNA region *a*, The features of ARS1 and deletion fragments, *b*, mobility of digested deletion plasmids *a*, All fragments were cloned into YRP14/CEN4[25] The wild-type (wt) fragment was inserted between the *Hin*dIII and *Eco*RI sites Deletions begin at the *Hin*dIII site and extend to the nucleotides indicated *Bam*HI octanucleotide linkers were added and the *Bam*HI/*Eco*RI fragments cloned into YRP14/CEN4 For bent DNA analysis wt DNA was cleaved with *Rsa*I and *Eco*RV which leaves 156 bp of pBR322 sequences (〰) adjacent to the *Hin*dIII/*Rsa*I ARS1 fragment For the deletion plasmids, DNA was digested with *Rsa*I and *Sph*I which leave 187 bp of pBR322 sequences adjacent to ARS1 fragments The lengths of the resulting fragments of interest are wt 467 bp, Δ108, 396 bp, Δ149, 355 bp, Δ173, 331 bp, Δ183, 321 bp, Δ197, 307 bp Electrophoresis was as in Fig 1, at 25 °C DNAs were also digested with enzymes that remove the pBR322 sequences and analysed on the same gel The wt fragment still migrates abnormally, but all deletion fragments Δ108-Δ197 now migrate with *k* values <1 05 (not shown) ARS activity for each plasmid was assayed by transforming the plasmids into yeast strain YNN318 (a/α ura3-52/ura3-52 lys2-801/lys2-801 ade2-101/ade2-101 trp1-Δ901/trp1-Δ901 his3-Δ200/his3-Δ200) Cells harbouring plasmids were transferred from selective yeast minimal plates containing glucose to yeast minimal media supplemented with galactose (Calbiochem) and grown for 16 h at 30 °C (selecting for the plasmid) and an additional 10 h without selection, then plated on nonselective galactose plates containing limiting adenine, cells containing the plasmids appear pink while those lacking the plasmid are red[25] The frequency of $\frac{1}{2}$ sectored colonies among colonies containing a single plasmid ($n=296$ to 2,000) was measured to determine the rate of plasmid loss per cell division Loss for wt and Δ108 plasmids was 4/1 1 0/2 0 segregation events while for Δ149 and Δ173 loss was >45/1 1 0/2 0 segregation events Loss rates are very high for Δ183 and Δ197 constructs, all colonies appear homogeneously red For Δ183 and Δ197 the number of plasmid-containing colonies plated was determined using selective glucose-containing plates When similar ARS activity experiments were performed using glucose media, the relative stabilities of the wt and Δ108-Δ197 plamids are unchanged, however, the overall plasmid stability is increased This medium effect is consistent with our observations that ARS plasmids are more stable on richer carbon sources[25,32] *b*, Polyacrylamide gel showing mobility of the digested deletion plasmids Left, DNAs analysed at 25 °C for 16 h, right, identical gel electrophoresis at 38 °C for 13 h Lanes are as indicated and described above Additional lanes are M_r, ΦX174 *Hae*III digested DNA (sizes indicated in bp), wt/*Rsa*, *Rsa*I the *Hin*dIII/*Eco*RI ARS1 DNA digested with *Rsa*I The 311-bp DNA fragment migrates coincident with a 356-bp DNA fragment at 25 °C (the 356-bp DNA fragment migrated 11% more slowly than expected on this particular gel)

cloned into YRP14/CEN4, a centromere-containing plasmid lacking an efficient replicator, and the rate of plasmid loss was determined by a colony colour assay (Fig 2)[25] Plasmids containing bent DNA (wild type and Δ108) are stable and lost at the rate of 10% per cell division The Δ149 plasmid, which lacks most of the bent DNA and half of the ABFI binding site, is fivefold less stable (Fig 2) Thus, the bent DNA region is important for ARS function *in vivo* It remains to be determined whether this effect is due to the bent DNA sequence, to the binding site for ABFI, or to both

Fig 3 DNA sequence in the bent DNA region of ARS1 All A residues that have neighbouring A residues are shown in bold type 10 5-nucleotide intervals and the ABFI binding site are also indicated A 25-bp region centred around this site is protected in DNase I protection experiments[20] The endpoints of deletions Δ108 and Δ149 are shown The ARS1 consensus sequence is located at position 241-251

Bent DNA has been previously discovered at the bacteriophage λ and SV40 replication origins[6,7,26] The discovery of such DNA at yeast ARS1 suggests that it may be important at chromosomal origins as well Although the precise role of the bent DNA at ARS1 is presently unknown, the position of this region suggests several interesting possibilities Since it is located at the 3′ end of the *TRP1* gene, it may be important for transcription termination Transcription through ARS1 has been found to reduce its activity (M S and R W D, unpublished observations) Thus one role of domains B and C might be to act as transcription termination segments to protect domain A The bent DNA with its associated protein could serve an important role in this process In addition, the region immediately adjacent to the ARS1 consensus element on a *TRP1* ARS1 plasmid (nucleotides 60-242) has been shown to be free of nucleosomes[27,28] Another function of the DNA bend might be to keep this region free of nucleosomes and readily accessible to the DNA replication apparatus and/or other proteins The origin region of SV40 DNA has also been found to be free of nucleosomes[29-31]

We thank Ron Sapolsky for his help with sequence analysis and Roger Kornberg in whose laboratory some of these experiments were performed This research was supported by NIH grant GM 21891

Flavonoid activation of nodulation genes in *Rhizobium* reversed by other compounds present in plants

J. L. Firmin, K. E. Wilson, L. Rossen & A. W. B. Johnston

John Innes Institute, Colney Lane, Norwich NR4 7UH, UK

Bacteria of the genus *Rhizobium* specifically recognize and infect legume plants, resulting in a complex morphological and biochemical differentiation into nitrogen-fixing root nodules. In *R. leguminosarum*, whose host plant is the pea, and several other *Rhizobium* species, groups of linked plasmid-borne genes are involved in nitrogen fixation (*nif* genes) and nodulation (*nod* genes)[1,2]. The *nod* genes are organized in several transcription units on the symbiotic plasmid pRL1JI of *R. leguminosarum*; these comprise *nodABCIJ*, *nodD* and *nodFE*[3–6] with *nodD* being a positively acting regulatory gene whose product activates transcription of the other two operons which contain genes essential for the nodulation process[5,7]. Although the precise biochemical functions of most of the pRL1JI *nod* genes are unknown, it has recently been discovered that their expression requires not only the product of the regulatory *nodD* gene, but also a factor (or factors) present in pea root exudate[5,7], and similar results have been reported for *Rhizobium meliloti*[8] and *Rhizobium trifolii*[9]. The finding of plant-produced products that 'signal' the *Rhizobium* offers the possibility of identifying one of the key biochemical reactions required for the infection process. Here we describe the characteristics of several plant-specified compounds that activate the transcription of the pRL1JI *nodABCIJ* and *nodFE* genes and present a novel phenomenon, namely that other, naturally occurring compounds can antagonize this induction.

For these studies the ability of different compounds to activate or to antagonize the activation of transcription of *nodABCIJ* and *nodFE* was monitored by the use of gene fusions Two *Rhizobium* test strains contained either the *nodC-lacZ* fusion plasmid pIJ1477 or the *nodF-lacZ* fusion plasmid pIJ1521, together with pIJ1518 which contains the cloned *nodD* gene[5,7] (Fig 1)

Preliminary studies showed the inducing compounds in pea root exudate to be soluble in water and methanol, dialysable and adsorbed by XAD-2 resin High-voltage paper electrophoresis showed that the active component(s) behaved as a weak acid Following high-voltage paper electrophoresis or paper chromatography (in several solvents) the region of biological activity co-migrated with material that absorbed ultraviolet light These characteristics suggested that the active component(s) could be phenolic HPLC fractionation of the exudate from germinating pea seeds showed four peaks of biological activity (Fig 2) with one (peak A) being the most prominent This was also the major peak in extracts from dried pea seeds and pea root exudate Although exudate from seeds of alfalfa, a legume not nodulated by *R leguminosarum*, could induce *nod* gene expression in this species, there were quantitative and qualitative differences in the peaks of biological activity compared with those from peas (Fig 2)

Electron impact mass spectroscopy (70 eV, 200 °C) of material in peak A from germinating pea seeds gave a complex pattern, with prominent ions at *m*/*e* 121 and 137 Although these might have been derived from simple phenolics, the presence of ions as large as *m*/*e* 256 suggested the presence of more complex phenolics One such class of compounds are flavonoids, these are made by plants and some give fragments of *m*/*e* 121 and 137

To confirm that flavonoid compounds were indeed inducers of *Rhizobium nod* genes, we took advantage of the fact that wild-type flowers of *Antirrhinum majus* contain many representatives of such molecules whereas a white flower colour mutant (termed *nivea*) which lacks chalcone synthase, contains none of these compounds[10] A methanolic extract from red wild-type flowers induced both *nodC-lacZ* and *nodF-lacZ*, whereas an extract from the white *nivea* mutant flowers did not Thus, one or more of the flavonoids in *A majus* flowers induces *nod* gene expression in *R leguminosarum* To confirm this, several commercially available flavonoids known to be present in *A majus* flowers, as well as other structurally similar flavonoids were tested as *nod* gene inducers (Table 1) Three flavones, three flavanones and one flavone glucoside induced *nod* gene transcription at low (10–100 nM) concentrations However, flavones and flavanones lacking a hydroxyl group on the B-ring had no inducer activity, vitexin (8-*C*-glucosylapigenin) and the 7-*O*-rhamnoglucosides of hesperetin and naringenin also failed to act as inducers Further, none of the isoflavones, flavanols or the flavone-3-glycoside tested had detectable inducer activity at concentrations as high as 10 μM

Two of the active compounds, eriodictyol and apigenin-7-*O*-glucoside, had identical HPLC retention times to peak A obtained from peas Evidence that peak A contained an *O*-glycoside of apigenin was that acid hydrolysis (2 M HCl, 100 °C, 2 h) of the material in peak A caused a reduction (by approximately 50%) of the inducing activity associated with this peak and generated a second, biologically active, ultraviolet-absorbing peak which had an identical retention time to authentic apigenin (Further, authentic apigenin-7-*O*-glucoside was hydrolysed using the same conditions used for the hydrolysis of the material in peak A, following separation by HPLC, it was found that all the apigenin-7-*O*-glucoside was converted to apigenin) Therefore peak A contained at least two biologically active compounds

The individual compounds tested for activation of *nodF-lacZ* and *nodC-lacZ* were also examined for their ability to antagonize or augment induction by extracts from pea seed exudate None of the compounds listed in Table 2 increased the levels of transcription of the *nodC-lacZ* or *nodF-lacZ* fusions However, it was found that, at concentrations as low as 5 μM, the isoflavones daidzein and genistein and the flavonol kaempferol strongly inhibited the activation of the *nodC-lacZ* fusion (Table 2), similar results were obtained with these compounds using the *nodF-lacZ* fusion

The second class of compounds tested as antagonists were analogues of acetophenone, which are structurally similar to the C-ring of the flavonoid *nod* gene inducers, several acetophenone analogues are known to induce transcription of the *vir*

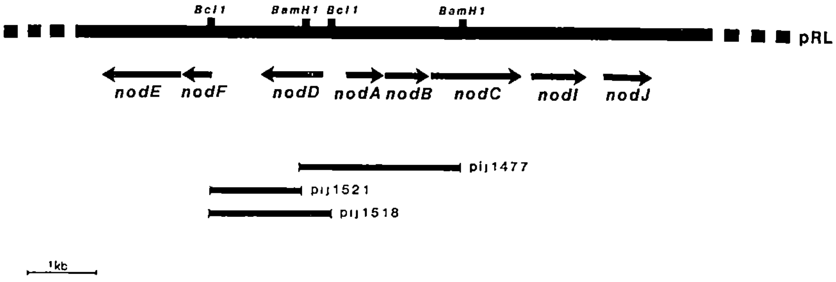

Fig 1 Location of pRL1JI *nod* genes Restriction sites used for the generation of the cloned *nodD* gene and the dimensions of recombinant plasmids used in this study The locations and directions of transcription of the eight *nod* genes are shown Restriction sites used for the generation of the cloned *nodD* gene in pIJ1518 (ref 7) and of the *nodC-lacZ* and *nodF-lacZ* fusion plasmids pIJ1477 and pIJ1521 (refs 7 and 5 respectively) are indicated

Table 1 Induction of *nodC-lacZ* expression in *R leguminosarum* by selected flavonoids

Compound	Biological activity* at flavonoid concentrations of 10 μM	1 μM	100 nM	10 nM
Flavones				
4′,5,7-trihydroxyflavone (apigenin)	5,163	4,649	541	59
3′,4′,7-trihydroxyflavone	6,814	1,069	109	64
3′,4′,5,7-tetrahydroxy-flavone (luteolin)	5,120	1,437	77	73
Flavone glucoside				
4′,5,7-trihydroxyflavone 7-*O*-glucoside (apigenin 7-*I*-glucoside)	5,964	3,642	239	55
Flavanones				
4′, 5,7-trihydroxyflavanone (naringinin)	4,552	3,154	100	58
3′,5,7-trihydroxy-4′-methoxyflavanone (hesperitin)	9,207	6,409	1,036	250
3′,4′,5,7-tetrahydroxy-flavanone (eriodictyol)	7,144	5,066	523	75

The *lac* fusion strain KH1122 pIJ1518 pIJ1477[7] was grown to a density corresponding to $A_{600} = 0\ 3$ prior to exposure to the flavonoid for 15 h at 29 °C with shaking The bacteria were then assayed for β-galactosidase activity as described previously[7] The following flavonoids had no detectable activity in the concentration range 10 μM-10 nM

Flavones 5,7-dihydroxy-, 5,7-dihydroxy, 3′,4′-dimethoxy-, 7-hydroxy-4′-methoxy-, 3,5,7-trihydroxy-, 3,4,5,7-tetrahydroxy-

Flavone glycosides 4′,5,7-trihydroxyflavone 8-*C*-glucoside, 3′,4′,5,7-tetrahydroxyflavone 3-*O*-rutinoside

Flavanone 5-hydroxyflavanone

Isoflavones 4′5,7-trihydroxy- (genistein), 4′,7′-dihydroxy

Flavanone glycosides 3′,5-dihydroxy-4′-methoxyflavanone 7-*O*-rhamnoglucoside, 4′-5-dihydroxyflavanone 7-*O*-rhamnoglucoside

* Biological activity is expressed as units of β-galactosidase activity In the absence of any added inducer the background level of expression was ~60 units

genes of *Agrobacterium tumefaciens*[11] None of these compounds induced *nod* gene expression but acetovanillone and 4-hydroxyacetophenone (at 50 μM) strongly inhibited induction of *nodC-lacZ* and *nodF-lacZ* by pea seed exudate (Table 2) At higher concentrations (1 mM) several other related phenolic compounds also strongly inhibited *nod* gene activation (Table 2) None of the compounds affected the growth rate of the cells

The results presented here show clearly that certain naturally occurring flavonoids activate *nodD*-dependent transcription of the *R. leguminosarum nodFE* and *nodABCIJ* transcriptional units and that this induction is antagonized by other flavonoids or simpler phenolics present in plants

In general, flavones and flavanones (Fig 3), which are hydroxylated in both the A- and B-rings, acted as inducers All flavonoids tested in which the C3 position was substituted with a hydroxyl group (flavonols), a sugar (flavone-3-glycoside) or phenyl group (isoflavonoids) were inactive At least one B-ring hydroxyl group appears to be necessary for inducing ability (for example 4′,5,7-trihydroxyflavone is active but 5,7-dihydroxyflavone is not) The B-ring hydroxyl can be at either (or both) the 3′ or 4′ position, thus hesperitin (3′-hydroxy-4′-methoxy), naringenin (4′-hydroxy) and eriodictyol (3′,4′-dihydroxy) are all active

The presence of a B-ring methoxy at the 4′ position appears to enhance potency, since hesperitin, the 4′-OMe-ether of eridictyol, is more active than eriodictyol itself However, no biological activity was detected when a 3′-methoxy- or 3′,4′-dimethoxy- was the only substituent on the B-ring (see Table 1) The glucosylated flavone apigenin-7-*O*-glucoside (but not apigenin-8-*C*-glucoside) acts as an inducer It is possible, though, that the 7-*O*-glycoside is deglycosylated by *Rhizobium* to form apigenin, itself an inducer of *nod* gene expression Moreover, the distinction between active and inactive flavonoids might reflect their differential uptake or metabolism rather than their (presumed) interaction with the regulatory *nodD* gene product

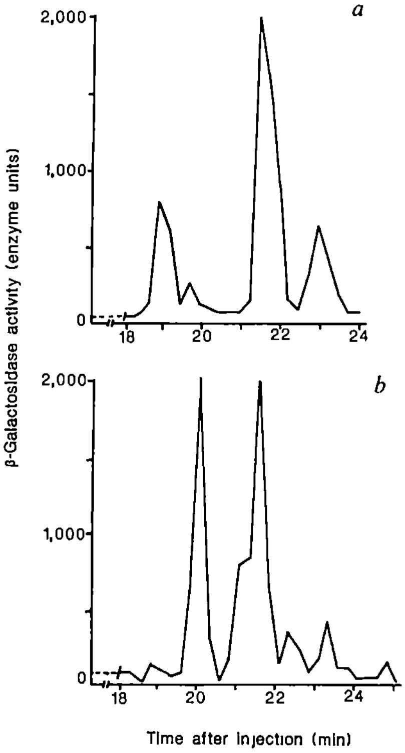

Fig 2 HPLC analysis of nod gene inducers present in the seed exudate from pea (*a*) and alfalfa (*b*)

Methods Seeds of pea or alfalfa were sterilized with aqueous sodium hypochlorite (50%) and were then soaked in sterile distilled water for 3 days with gentle shaking The liquid was removed, and after centrifugation (5,000*g*, 15 min) the supernatant was concentrated *in vacuo* (45 °C) and was applied to a preparative reverse phase (C8) HPLC column (12 cm × 0 7 cm) The column was eluted at 2 ml per min with a linear gradient of methanol-water, from 10% to 99% methanol at 3 2% per min, and fractions of 5 ml were collected After evaporation, a portion of each fraction was assayed for *nod* gene-inducing ability using *nodC-lacZ* fusion[7] Active fractions were combined, concentrated and applied to an analytical HPLC column (Brownlee Aquapore RP300, 25 cm × 0 46 cm fitted with a 3 cm × 0 46 cm guard cartridge) The column was eluted at 1 ml per min with a linear gradient of methanol-water (0-3 3 min, 10% methanol, isocratic, 3 3-24 7 min, 10-85% methanol, linear gradient, 24 7-28 1 min, 85% methanol, isocratic, 28 1-32 0 min, 85-10% methanol, linear gradient) Fractions (0 25 ml) were tested for the ability to induce *nod* gene expression as described above Similar results were obtained with the *nodF-lacZ* fusion instead of *nodC-lacZ*

Activators of *R. leguminosarum nod* gene transcription were found not only in pea, which is nodulated by this species of *Rhizobium*, but also in extracts of alfalfa, clover and cowpea plants which are not nodulated by *R leguminosarum* Thus host range specificity cannot be determined solely on the basis of *nod* gene inducers such as the active flavonoids described here

Further, the flavone luteolin was shown to be the major active component present in alfalfa seeds for the induction of *nodABC* transcription in *R meliloti*[12] This flavone also activated *R. leguminosarum nod* genes (Table 1) HPLC analysis of extracts of peas and alfalfa seed showed that they both contained several molecules with inducing activity In peas the most prominent peak on HPLC (peak A in Fig 2) contains at least two componds (this would explain the complexity of the mass spectrum) Taken together the evidence from chromatography, mass spectroscopy and acid hydrolysis strongly suggested that the material in peak

Table 2 Effect of selected flavonoids and acetophenone analogues on *nod* gene expression in *R. leguminosarum*

The *lac* fusion strain KH1122 pIJ1518 pIJ1477[7] was pregrown to an absorbance (at 600 nm) of 0.15 prior to exposure to the compound under test, in the presence cf a fixed amount of natural inducer (obtained from germinating pea seeds) equivalent to 2,000 units of β-galactosidase activity. The bacteria were shaken for 15 h at 29 °C and were then assayed for β-galactosidase activity as described previously[7]. ND, not determined.

A contained apigenin-7-*O*-glucoside plus another flavonoid which had the same chromatographic behaviour as eriodictyol. Further, Redmond *et al.*[13] found that in clover the major activator of *R. trifolii nod* gene transcription was 7,4′-dihydroxy-flavone.

The finding that other naturally occurring compounds made by plants inhibit *nod* gene induction by flavonoids is novel. Those flavonoids which were most potent in antagonizing induction had hydroxylation patterns in the A- and B-rings similar to those of the inducing flavonoids described here but different from the inducing molecules in having a substituted C3 position, as in the isoflavonoids genistein and daidzein and the flavonol kaempferol. Flavones lacking a B-ring hydroxyl (for example, 5,7-dihydroxyflavone) were much less inhibitory. Given the structural similarities between antagonists and the inducing molecules it is possible that they act competitively either at the level of transport or within the bacterial cell. The substitution pattern of the acetophenone analogues tested also had a marked effect on their potency as inhibitors of *nod* gene induction, the most potent of this group were those which had a substitution pattern [(3-methoxy, 4-hydroxy-) or 4-hydroxy-] similar to that found in the B-ring of the flavonoids that induced *nod* gene transcription.

There is an apparent paradox in the fact that isoflavonoids were among the most potent antagonists of *nod* gene transcription, *a priori*, it might have been thought that isoflavonoids,

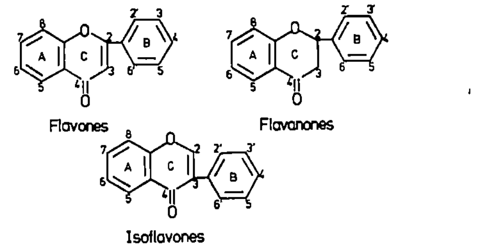

Fig. 3 Skeleton and numbering nomenclature for the flavonoids mentioned in this study.

which are found predominantly in the family Leguminosae[14], would be good candidates for compounds that activate the expression of *Rhizobium nod* genes.

The concentrations required for antagonism of induction by, for example, the isoflavonoid daidzein were one to two orders of magnitude greater than the concentration required for *nod* gene induction by the most potent of the activating molecules. However, isoflavonoids are present in germinating legumes at concentrations as high as 20 μM even in healthy plants[15]. It seems likely therefore that, during the normal nodulation process, the regulation of *Rhizobium nod* genes is subject both to activation and to the antagonism of activation by different plant-specified molecules. Indeed, compounds were found in pea root exudate which antagonize the induction of the *nodC-lacZ* fusion by the inducing compounds in peak A. This was demonstrated by fractionating root exudate by the HPLC and adding individual fractions of exudate to a strain carrying a *nodC-lacZ* fusion which had been grown in the presence of the inducer (C. A. Shearman, personal communication). The host plant legume can regulate the number of nodules it contains on its root system. This has been clearly demonstrated by the fact that mutants of soybean[16] and of pea[17] have been isolated which contain many times more nodules than wild-type. Further, when a recombinant plasmid containing the cloned pRL1JI *nodABC* genes, transcribed constitutively from a vector promoter, was introduced into a wild-type strain of *R. leguminosarum* nodulation of peas was severely inhibited[18] indicating that continuous high-level transcription of these genes is deleterious for the infection process. It will be of interest to see if the control of nodule number depends upon the extent to which the *nod* genes are expressed, this being determined by the relative concentrations of the inducers and anti-inducers which are present in the rhizosphere and in the plant root tissue.

We thank Keith Parsley for mass spectrometry, Enrico Coen for providing *Antirrhinum* plants and David A. Hopwood for useful discussions about the manuscript.

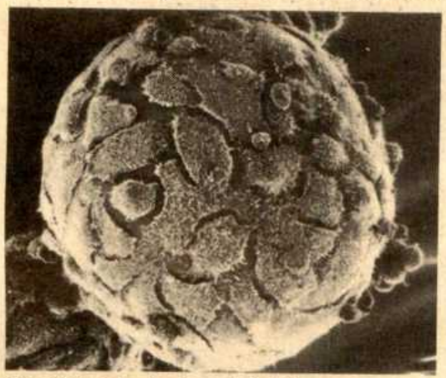
Notes for the laboratory

From cell culture products to an expert program, this week highlights innovative and useful ideas.

Ventrex Laboratories, Inc. has recently introduced **neutrally buoyant glass microcarrier beads** (Reader Service No. 100). Typical Ventreglas beads have a specific gravity of only 1.03 making the vigorous stirring speeds that retard cell growth, but are required with heavier beads, unnecessary. Ventrex's beads are polystyrene coated with glass, and are therefore capable of withstanding cleaning by trypsinization, chromic acid, or alcohol. Ventreglas beads are also autoclavable. The beads come in a variety of diameters ranging from 90–210 µm, and a 25 g sample is available for $100 (US).



The Ventreglas bead: unsinkable

Statistical Programs' new expert computer system, EXPERtIMENTAL DESIGN, eases the selection of **statistical designs for data analysis** (Reader Service No. 101). Through a question-and-answer format, the program ranks the suitability of 13 designs, ranging from factorial to Box-Behnken analysis, to the user's experiment. Uncertainty in the user's answers is dealt with by assigning desirabilities and manipulating them according to fuzzy set theory. Accompanied by a user's manual including a tutorial, the programmed floppy diskette sells for $295 (US), and is written for 256K IBM PC/XT/AT.

Mycoplasma contamination need not plague your cell cultures and influence your experimental results, now that the American Type Culture Collection is offering their new **mycoplasma detection service** (Reader Service No. 102). ATCC's procedure costs $50 (US) each for 1–10 samples, and utilizes both a direct and an indirect assay to determine if suspect cultures are affected. The direct assay involves a total incubation time of 28 days, according to ATCC, while the indirect assay (using a fluorochrome staining procedure) can be accomplished within a week.

The membrane-based **culture plate inserts** for epithelial cell culture available from Millipore allow *in vitro* cultures to closely mimic cells grown *in vivo* by providing cells with both serosal and mucosal contact with media (Reader Service No. 103). Millicell-HA inserts come presterilized in blister packages for convenience, and are produced in a 12 mm configuration to fit 24-well plates, as well as a 30 mm configuration appropriate for 6-well plates. Available since June 1986 in the United States, Millicell-HA inserts are now available in the United Kingdom, and are priced at £50–70 (UK) (depending on size) for a box of 50.

Taconic, Inc. eliminates worries over **clinically silent infections in laboratory animals** with its free bimonthly *Lab Animal Health Report* (Reader Service No. 104). Each edition will feature a different strain, and will outline the battery of tests to which Taconic mice and rats are subjected, along with ratios of incidence of infection. Available to any researcher using mice and rats, Taconic's reports will allow experimenters to exclude subclinical infection from other influential variables in the interpretation of results. ☐

These notes are compiled by Carol Ezzell from information provided by the manufacturers. To obtain further details about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal and apply only within the country indicated.

ADVERTISEMENTS

SAFE-FRIT™ FUNNELS

Safe-Lab's NEW fritted glass funnels feature a removable, unbreakable polypropylene stem just below the fritted glass disc. This unique design eliminates the danger of broken glass funnel tips and permits easy cleaning from both sides. Removable stem allows you to set the funnel top on counter or directly inside an oven or desiccator for drying, without the danger of tipping or spilling. Polypropylene has excellent chemical resistance and threads will not leak, even at high-vacuum.

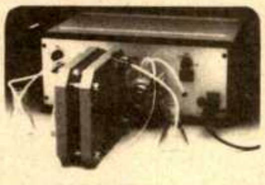
LIPOSOMES
REPRODUCIBLE – HOMOGENEOUS – EXTREMELY RAPID

NEW



Our new LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized unilamellar liposomes. Liposome size is selectable between 25 and ca. 600 nm diameter. Sample volume is normally 5-10ml or up to 200ml if used in combination with an additional instrument. Lipid concentration can be up to 300 mg/ml.

Reader Service No.35

The changing graduate labour market

Richard Pearson

Competition between employers for the best UK graduates is becoming intense.

As the new academic year gets under way, final-year undergraduates have to face up to the twin pressures of final exams and job hunting. While 1987 promises to be another bouyant year for graduate recruitment, the traditional pattern of the annual 'milkround' is coming under increasing strain as employers seek the 'best' graduates at a time when the universities are producing fewer graduates.

Thus, alongside generally booming job prospects, the graduate labour market is showing clear evidence of fragmentation, reflecting a more general trend in the labour market as the market becomes 'freer' and employers compete intensively for the 'best' and for specialist skills, offering increasing salary differentials and special premiums for quality staff, while those with less marketable skills suffer at the bottom end of the labour market chasing low paid and often temporary jobs, or experiencing bouts of unemployment. As a result, while 1985 saw the largest ever number of university graduates entering employment, unemployment six months after graduation remained at significant levels, 8.6 per cent, although this was somewhat lower than in previous years (Table 1) and compares favourably with unemployment in the population at large.

This year well over 100,000 students graduated with first degrees, with the universities accounting for two out of three graduates, and the polytechnics and colleges one in three. The majority graduated in arts and social science subjects, with under 15 per cent being engineers and technologists, while a further 28 per cent were scientists (Fig. 1). Not all of those graduating, however, seek to, or actually enter the labour market, about one in four going on to further academic work or formal training (although only 3,200 went into teacher training in 1985, a fall of over 40 per cent since 1981) while about one in six were unemployed or otherwise not available for work six months after graduation. The 33,500 university graduates going into employment were split in roughly equal proportions between public service/education, industry, and finance/commerce, with the latter having shown the most growth during the past five years.

Table 1 Graduate unemployment

	Unemployment six months after graduation (%)	Entering permanent employment
1979–80	9.0	29,882
1980–81	11.3	28,523
1981–82	13.5	29,602
1982–83	11.6	32,506
1983–84	9.6	33,942
1984–85	8.6	34,717

Source: University Grants Committee

Interestingly, while the numbers entering jobs in industry had grown steadily between 1980 and 1984, they fell slightly in 1985. For this year the forecasts have been of a five per cent increase in overall vacancies with particular growth being shown in the fields of transport, government, public utilities, financial and other services. The decline in engineering and other manufacturing vacancies is expected to continue.

Traditionally the vast majority of graduate vacancies have been advertised and filled through the annual 'milkround', when employers visit the campuses in the spring term, announcing their vacancies and carrying out first interviews. Nowadays, however, an increasing number of employers are starting their visits before Christmas and making job offers much sooner in order to be able to select the best staff. The numbers doing this have risen from 12 to 17 per cent of recruiters in the last three years (*The Cost Effectiveness of the Graduate Milk Round*, IMS, 1986). At the same time more and more vacancies are being advertized through the summer fairs, with over one in three recruiters using them in 1986, some to compensate for shortfalls from the milkround but also because some new vacancies appear in the summer months. More students also appear to be delaying job-searching to concentrate on their exams, secure in the knowledge that good jobs will be available in the summer months. Thus while the milkround remains the dominant recruitment method, the graduate labour market is becoming less concentrated in time.

Another sign of the fragmentation of this part of the labour market is the increasing range of starting salaries being offered. In the early 1970s virtually all graduates received similar starting salaries with only small distinctions being made between different types of employers and little distinction being drawn between graduates from different disciplines. By the late 1970s, premiums were being paid to engineers in shortage disciplines, and with the demise of incomes policies, more emphasis on market forces and increased competition, the diversity of starting salaries has increased markedly. For example, in 1986 the median graduate starting salary was about £8,000 per year, but with an upper decile of £9,000 and lower decile of £6,750. The annual rate of increase at the top of the range of 9 per cent was double that at the bottom, further widening the gap.

Last week's 'Big Bang' in the City of London had also had a highly publicised impact on graduate salaries, with 1986 seeing many examples of new city recruiters offering starting salaries of between £10,000 and £13,000 per year — in several cases even more. Looking to 1987 it seems clear that many more financial institutions will be offering starting salaries in between £12,000 and £14,000 a year, which will be well ahead of the likely average of about £9,000 for most jobs. With golden hellos also being paid (one merchant bank, for example, giving 'bursaries' of £2,000 to let graduate recruits 'travel in the summer vacation'), decisions about jobs and careers can become even more complex.

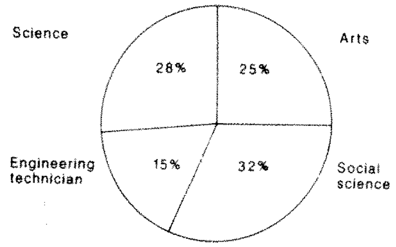

Fig. 1 Subject distribution, all institutions. (Source: University Grants Committee.)

The key for job hunters is to look beyond the short-term rewards of salary and also think about job interest, training and experience, and the longer-term career development prospects, which may be gained through several firms. While these latter factors can often act as compensation for a lower starting salary, the disturbing feature of many jobs on offer is that the lower salaries are often combined with the poorer training and career prospects, further emphasizing the fragmentation of the labour market into a smaller elite of highly rewarded and well trained staff, pulling away from the broader range of jobs available to the majority, and unemployment or underemployment facing a significant minority. ☐

nature

What price independence?

The British government has scraped together a little money to save its universities from catastrophe, winning in return a series of promises that academics may not be able or willing to keep.

BRITISH universities cannot afford to decline last week's offer of extra funds (see p. 97), but they will pay a high price for only a little extra. Not that the strings attached to the offer by Mr Kenneth Baker, the new Secretary of State for Education and Science, are all that onerous. He demands selectivity in research, the elimination of small departments, better management, the abolition of academic tenure, more technology transfer to industry, more explicit concern about academic standards and more help with the supply of mathematics and physics teachers in the schools. What could be more reasonable? Unfortunately, there is a catch.

What Mr Baker asks is not new. Some of his requests are even matters on which the university system itself has taken the initiative. Selectivity, for example, has been a slogan for at least twenty years. More recently, it has been the practical response of the University Grants Committee (UGC) to the shrinkage of its budget; its intention to concentrate part of its funds on institutions with a reputation for research is two years old, but began painfully to bite with this academic year. Similarly, for better or worse, British universities are now thoroughly steeped in the doctrines on management put out last year by what is called (after the chairman of a committee) the Jarratt report, commissioned jointly by the Committee of Vice-Chancellors and Principals and UGC. So why fear the gift of extra funds when the strings attached require largely the pursuit of present goals?

The obvious danger is that the prudent intentions of titularly autonomous institutions are turned into external obligations that can (and will) be monitored. Selectivity? A single civil servant in his spare time will be able to inspect the disparities in the treatment by UGC of individual universities and complain if they are too small. Better management? UGC has undertaken to carry out the first invigilation itself. Academic standards? The vice-chancellors, after what has evidently been a busy summer, have put out a mixed dossier of codes of practice (on matters such as the training of academic staff and the role of external examiners) and of half-considered means of assessing academic performance (citation counts, for example), giving further hostages to the external monitors. The vice-chancellors have even promised to produce a report on present practices of awarding academic tenure; without promising to abolish tenure, the vice-chancellors' letter promises to "aim" at ensuring that people "are not initially appointed with tenure in its strongest form where this can be avoided".

Accountability

But should not universities supported by public funds be publicly accountable? Of course. The danger in the new relationship between the British government and its universities is that the social and economic value of the academic system will be judged by criteria devised for managerial purposes only. It should be especially galling for academics, and alarming as well, that Baker was able to attach to last week's written statement copies of letters from the chairmen of UGC and of the vice-chancellors' committee embodying written promises that they will conduct themselves appropriately in the future.

How could that have come about? In the idiom of British public life, the circumstances are easily reconstructed. Baker differs from Sir Keith Joseph, his predecessor, in preferring to make friends rather than enemies. He is also adroit, so much so that the failure of his first project for the present government, the reinvigoration of the British economy by the encouragement of cable television, has left his reputation unscarred. At some early meeting with the chairmen of UGC and the vice-chancellors' committee, he would have explained that he personally is sympathetic to their difficulties (and appalled at the prospect that one or more universities might have to close), would have added that the government in which he shares collective responsibility is unfortunately convinced that academics are an expensive bunch of unproductive layabouts, would have listened sympathetically to the universities' account of how strenuously they have tried to put their own houses in order (and would generously have advised them to spend more on making their efforts better known), would have offered to fight hard for a little extra cash in the run-up to the annual settlement (last week) of next year's public spending and, pleading that he himself would be occupied trying to bring the semblance of indusrial peace to British schools, would have asked that academics should help him and their own cause by providing the ammunition he would need.

Contrition

The sting has worked. There will be a little extra money. Baker's civil servants would have provided guidance (in the British idiom) about the kind of ammunition they would need (but their first proposal for a tripartite statement appears to have foundered, improbably at a gathering of academics in Penang). But Baker has been able to deliver to his colleagues a prize that eluded his predecessor — a show of contrition for imagined misdemeanours by the universities, a promise to do better in future and a set of measuring-rods with which they may be beaten if the occasion arise.

Nothing that happened last week touches the true problem of the British university system, which is structural and neither financial nor managerial. The universities boast that they are autonomous, but that is less than half the truth. In reality, they are public corporations almost totally dependent on public funds (on UGC and on local education authorities for their teaching functions, on the research councils for research). In the halcyon 1960s, when the only problem was that of investing quickly enough in higher education, UGC's performance easily upheld the British conceit that it is a uniquely judicious way of channelling public funds towards private ends.

The novelty, now, is that British governments, having become by accident providers of higher education, have also for some time become disenchanted with the product (or at least persuaded that higher education can be had more cheaply in other kinds of institutions than universities). UGC, no longer able to act the benefactor, has taken to telling particular institutions that they cannot teach this, or that ... or else. One of UGC's latest projects, an enquiry into the viability of "small" departments of physics and chemistry, will almost certainly discover that they are financially uneconomic and will recommend that they should be abolished or amalgamated. UGC will regret, like the institutions concerned, that universities thus deprived will hardly meet the classical concept of the university.

Especially under its present enlightened management, there is no reason to believe that UGC wants to become what it is well on the way to being — every British academic's dean's office. Nor can Baker seek the kind of centralization now being forced on the system by financial stringency. He should know that there is a respectable way out, one that would get the government out of the business of setting the specific goals by which universities conduct themselves. He would be nudged in that direction if the committee now looking at UGC's own function, due to report in the next twelve months, recommends regretfully that UGC should be abolished.

But how could British universities survive without UGC? By being challenged with the offer of the autonomy of which they boast. It is now five years since they were told (by UGC) that they would be penalized financially if they exceeded certain student numbers; the threat of penalty has been lifted, but target student numbers remain the basis on which UGC allocations are calculated. One result is that successful universities cannot grow as quickly as they might, while less successful institutions are kept in being, at least in the short run, by continuing subventions. The prospect, as UGC enforces rationalization for sound economic reasons, is that many of these institutions will become lop-sided places, covering only part of the ground of scholarship and thus even less suitable for, and probably even less attractive to, potential students. The truth is that British universities are, on the average, too small for the smaller among them to be complete. Their size probably makes them uneconomic as well. The general interest would be served by amalgamation, for which, under present arrangements, there is no incentive.

But how could autonomy be afforded? Curiously, the financial problem is not nearly as insurmountable as it may seem. A third of the UGC budget is reckoned to cover research support, leaving £1,000 million a year in round numbers for the support of other academic functions in universities. Public funds are channelled to institutions of higher education in the form of tuition fees fixed far below average or even marginal cost. Although local authorities administer the system, central government meets the cost. So why not allow tuition fees to rise again (they were arbitrarily cut four years ago when Baker's predecessor feared they would partly protect some universities from the penalties for quota-breaking), meeting the cost from the central budget of UGC? If managed over a predetermined period of time, and coupled with the understanding that students would choose between universities, the result would be both autonomy and a measure of competition between institutions at present persuaded that they must all sink together.

But, Baker's civil servants will ask, what assurance will there then be that the universities are publicly accountable? How will it be possible to tell that academics are indeed carrying out a modicum of research, or that they are taking full account of citation counts in promoting their own members to more senior posts? These questions are of course irrelevant. If the universities were financially autonomous, dependent on public funds only indirectly through the preferences of students for courses of study and for places at which to follow them, the universities would have an incentive which they at present lack to manage their affairs efficiently. They would also have an incentive towards diversity, of which Britain has too little. The endless quarrel with the government about tenure as universities came to put their institutional survival before the interests of individuals would end. Some might even discover that they need not stick slavishly to UGC "norms" for the number of students per member of teaching staff any more than they are compelled to follow UGC standards for the equipment of buildings. To be sure, in such a regime, only the better universities would prosper. Is there anything wrong with that? □

Research in trouble

Mr Baker's little extra has also created a dilemma in which leaving CERN may be the only choice.

THE research half of the British academic enterprise will be hardly better pleased than the university part with last week's events. Outwardly, the research councils will have an extra £39 million to spend next year, over and above inflation, or more than 6 per cent of total public support for basic research. One immediate snag is that £14 million of the extra offered last week was also offered just under a year ago by Sir Keith Joseph, and has long since been counted on by the Advisory Board for the Research Councils (ABRC) on whose advice the sum available is eventually divided among the five research councils. Another and more serious difficulty is that the British basic research enterprise is yet again in the throes of a crisis thrust upon it by circumstances over which it has no control. Sterling has once again depreciated, with the result that the Science and Engineering Research Council (SERC), which must find from its budget international subscriptions to organizations such as CERN, the European high-energy physics laboratory, is short of roughly £20 million, nearly a quarter of what it spends each year on research grants to academics. ABRC will have a stark choice at its two meetings later this month: either give the whole of Mr Baker's extra money to the research council in most urgent need of it, letting the others smoulder in penury for another year, or invite SERC to face a decision that has been staring it in the face for the past three years, whether to pull out of CERN.

It is a curious state of affairs. Except for 1980, when sterling appreciated against European currencies (and SERC's predecessor spent its windfall gain on extra equipment grants for universities), the crisis is chronic. Nobody is astonished, for sterling is a steadily depreciating currency. To saddle the research councils with this perpetual difficulty is of course unfair; while the international organizations to which SERC subscribes have scientific objectives, the government also has a political interest in their continuation. With its new policy on space research, the British government would not readily agree to a decision of SERC to save its annual subscription to the European Space Agency by pulling out of that. British membership of CERN is a political matter for different reasons; the British government has an interest in seeming no less faithful a European state than its competitors. But, with the exception of a single year when the Treasury was persuaded to do the decent thing, there has been no occasion in the past decade when the research councils have been adequately bailed out. Members of the council's peer review committees meeting in the past few weeks to consider new grant application have been startled to be told that SERC is £20 million short, for which reason it may be necessary to postpone the dates at which some successful applications become effective. Of necessity, the grants postponed will be those that can be put off practically; they may well include the more promising projects, which is no way to run a research enterprise already low on morale.

This is why withdrawal from CERN is yet again a live issue. ABRC's own inquiry under Sir John Kendrew concluded that it would be better, first, to negotiate a reduced budget (or British contribution), which is now the purpose of a study by CERN members due to be completed next year. It would be discourteous to pull out before that review is completed, but SERC may have no choice. The way things have turned out in Britain, with the research community persuaded that the future is only bleak, the decision may not matter much. But if there is a chance of rescuing something from the British enterprise, it is more important to give a few young people with bright ideas a chance to turn them into reality than to continue membership of even such a splendid organization as CERN. But if SERC goes down that road, it should promise itself and its constituents that it will also look hard at the need for all of its own domestic facilities. □

British penury relaxed

Increases for universities just avert disaster

BRITISH universities and the research councils are to benefit from a modest cash injection in the two years from next April. This is their share of a £4,000 million package of spending increases unveiled last week by the government, and widely taken to be part of the preparation for the next general election, which must be held before the spring of 1988.

Although education as a whole receives the lion's share of the whole package, which includes £460 million for the improvement of the pay of teachers in schools, the universities are unimpressed with their share. This amounts to an extra £61 million in 1987–88 and an extra £71 million the following year. The research councils are to get an extra £39 million a year, beginning with the next financial year next April.

The Committee of Vice-Chancellors and Principals (CVCP) welcomes the extra funds as anybody would welcome "water after years of drought", saying that the new budget will do little more than avert disaster. CVCP was especially indignant at the meagreness of the increase for the research councils, saying that the sum is not only disappointing but that it does not compare with the investment in research by Britain's industrial competitors.

Announcing the increases last week, Mr Kenneth Baker, Secretary of State for Education and Science, more than hinted that there are strings attached. In particular, the university increases are dependent on continuing progress in the rationalization of research and the channelling of sufficient funds into applied research.

Baker, who succeeded Sir Keith Joseph as secretary of state only in June, said last week that he "would expect" the University Grants Committee (UGC) to provide for some early retirement and the recruitment of new young academic staff and special initiatives in teacher training to help deal with the shortage of teachers of mathematics, physics and technology in British schools.

The execution of this policy is in the hands of UGC, which began the process of selectivity last May, when universities were told individually that public support for this academic year would for the first time be linked with research performance. The equity of that unequal distribution of funds was widely disputed (see *Nature* **322**, 299; 1986); by the end of next year UGC and the research councils are to produce a joint statement of the criteria that will be followed in the further pursuit of selectivity in research.

Kenneth Baker's cash has strings attached.

Meanwhile, UGC says that whatever the funds available through the research councils, "universities separately need to draw up and carry out plans for the selective distribution of the resources they devote to research". This will lead to "better research through the concentration of effort in strong departments".

British universities are also under continuing pressure to improve their internal management along lines recommended by the Jarratt committee in 1985; responses by individual universities are now in the hands of UGC. The government is also pressing for common criteria of academic quality and the abolition of academic tenure.

UGC is responding to the further pressure to rationalize the pattern of university activity in Britain by a series of reviews of academic areas. Reviews have already been completed of teaching and research in pharmacy, agriculture, oceanography, Italian and Scandinavian studies.

There will be further pressure on the university system later this month, with the planned publication of a Cabinet Office report on publicly supported research. The government has not hidden its discontent with the efficiency with which research is transferred from universities and government research establishments to the commercial sector. **Bill Johnstone**

Meningitis

Puzzling cluster in rural Britain

THE incidence of meningitis in the small English parish of Stonehouse in Gloucestershire, which is 14 times the British average, has now prompted the British Department of Health to mount a special investigation. Forty doctors, nurses and scientists will shortly complete the first phase of a programme to try to determine the reason. It is hoped that the 7,000 residents of Stonehouse will agree to be tested.

The subject of the study is principally a bacterial strain of meningococcal meningitis (B15R) which is resistant to Group B Type 15 sulphonamide. In the past five years, 53 cases of meningitis, mostly B15R, have been diagnosed in the Stroud area of Gloucestershire (population 103,600), which includes Stonehouse. Since 1984, Stonehouse has recorded 10 out of 12 diagnosed cases of the disease from among the 2,000 people living on one housing estate. The national average for the incidence of meningitis is 1 per 100,000 of the population. The incidence in the Gloucester district is five times that figure, and that of Stroud is double again with 9 cases per 100,000.

The research project is being coordinated by Gloucester Public Health Laboratory and the Gloucester Health Authority with support from the Department of Health and Social Security (£57,000) and the Meningitis Trust (£20,000), a charity recently established in the Gloucester area to fight the disease.

The volunteers in the programme will submit themselves to swabs and blood and saliva tests. The results of the first two categories of data are expected to identify the carriers of the disease and those with immunities; it is hoped that the other, conducted by a team from the University of Edinburgh, will indicate the type of person susceptible to contracting it. The Edinburgh team hopes to substantiate its theory that those who do not secrete blood group substances into their saliva are more likely to develop meningitis.

Although the disease can be successfully treated with antibiotics if diagnosed early, some young victims have died within two days. Fever, rash, vomiting and eventual coma are the classic symptoms. But although the under-fives are more susceptible to the ordinary form of the disease, the B15R strain is claiming many of its victims from among young adults, most of them teenagers.

The numbers of diagnosed cases of meningitis peaked in 1974 with 1,296 cases and dropped to an all-time low ten years later with 404. But last year the figure was 549 and 900 cases are expected this year.

Bill Johnstone

US mid-term elections

Power jockeys in new race

Washington

Last week's elections put the Democratic Party front and centre on the Capitol Hill stage. With control of both the Senate and the House of Representatives, the Democrats will carve up the spoils of their victory in the next few weeks, chiefly the chairmanships of the committees that determine the legislative agenda for the next session of Congress. But a new majority party will hardly be a panacea for budget troubles, and the Republicans will now have the luxury of watching the Democrats make the difficult choices.

The Democrats gained control of the Senate, and now enjoy a 55–45 majority. Several extremely close races delayed final calculations, but the Democrats will add at least 5 seats to their 253–182 majority in the House of Representatives. Ironically, several of the Republicans being replaced as Senate committee chairmen are reckoned more liberal than their Democrat successors. An example is John Stennis, a conservative southern Democrat, who takes control of the powerful Appropriations Committee from Mark Hatfield, a liberal Republican from Oregon.

The chairmanships of the key appropriations subcommittees controlling the purse strings for the National Science Foundation (NSF) the National Institutes of Health (NIH) and other government science agencies are still uncertain, but present chairmen have treated science agencies generously. Lowell Weicker (Republican, Connecticut) has been a strong ally of NIH as chairman of the health subcommittee, and Utah Republican Jake Garn has been favourably disposed toward NASA (the National Aeronautics and Space Administration) as chairman of NASA's subcommittee. Garn was a passenger aboard the space shuttle in 1985.

The Strategic Defense Initiative (SDI), already under attack in Congress, will probably face greater resistance from the Democrats taking over military and energy committees. Both Sam Nunn of Georgia and Louisiana Democrat J. Bennett Johnston have criticized SDI.

A dramatic philosophy shift will occur on the Labor and Human Resources Committee when Orrin Hatch of Utah steps down in favour of Edward Kennedy of Massachusetts. Hatch, a conservative, has been an outspoken opponent of abortion, favouring a constitutional amendment making it illegal. Kennedy is a liberal and a strong proponent of government-supported health-care programmes.

In the House of Representatives, membership of science committees is unlikely to change substantially. The most significant difference will be the departure of Don Fuqua from the House Science and Technology Committee. Fuqua, who retired this year and will take a job as a lobbyist for the space industry, will be replaced by Robert Roe of New Jersey.

Although science agencies fared relatively well in the most recent budget cycle, next year will probably be a different story. The Gramm–Rudman deficit reduction act will force still larger cuts to reduce the budget deficit.

William Wells of George Washington University, who follows congressional science policy for the American Association for the Advancement of Science, says a harbinger of next year's problems was seen in the House of Representatives appropriation for the NSF research budget. Although NSF has received favourable treatment from the Democrat-controlled House, this year the appropriation for NSF-sponsored research was $146 million less than the administration request.

With only a fixed amount of money to dispense, the House subcommittee chose to protect certain housing and environmental programmes at the expense of NSF. In the final budget compromise with the Senate some of that money was restored, and overall NSF received about an 8 per cent increase in funds. According to Wells, in the next Congress just holding steady will be a "a remarkable achievement". **Joseph Palca**

British SDI cash

The value of SDI contracts in Britain has not so far approached the reported $1,500 million target sought by British politicians at the outset, but their total value now exceeds $14 million. Contracts and subcontracts include, according to the Federation of American Scientists and the Council on Economic Priorities, Barr and Stroud $250,000; Cap Scientific $250,000; British Aerospace $1.25 million; Ferranti $508,000; General Electric (UK), $1.75 million; Hunting Engineering $1 million; Logica $700,000; PA Defence Services $750,000; Plessey $1.45 million; Racal $250,000; Scicon $250,000; Short Brothers $250,000; Thorn EMI $500,000; UK Atomic Energy Authority $4.3 million; UK Ministry of Defence $1.4 million.

The Science and Engineering Research Council's Rutherford Appleton Laboratory is also now negotiating a $15 million research contract for the Super-Sprite Laser Facility. In the British Isles those doing SDI work include University College, Cork, Heriot-Watt University and the University of London. Tim Beardsley

Strategic defence

SDI should change course

Washington

Research for the Strategic Defense Initiative (SDI) continues to be an obstacle to superpower arms negotiations, but a compromise on defensive research that meets the legitimate interests of both sides should be possible, according to the Aspen Strategy Group, an independent think-tank.

The group's study, *The Strategic Defense Initiative and American Security*, published on 22 October, is critical of the current SDI programme, saying its large-scale mockups are inadvisable for technical reasons and erode confidence in the Anti-Ballistic Missile (ABM) Treaty. But the Aspen group says "progress towards a new [strategic arms] agreement should be possible" if the United States modifies its position that all development and testing of space-based defensive systems is allowed, in return for the Soviet Union dropping its demand that only laboratory research is possible.

The co-chairmen of the Aspen study were William J. Perry, a former undersecretary of defence under President Carter, and Lt-Gen. Brent Scowcroft, national security adviser to President Ford. The group includes senior politicians, academics and representatives of industry.

The group sees valuable opportunities to trade arms cuts for a commitment not to give notice of withdrawing from the ABM treaty for 10 years — this would mean forfeiting "very little in technical terms". The study finds "virtually no prospect" of a significant and effective population shield against a responsive enemy this century. And it says the SDI programme's large field experiments "appear to be driven by political considerations" and risk "freezing in" technologies prematurely in what should be a long-term programme.

The Aspen group also says the United States has conducted SDI experiments "whose consistency with [the ABM treaty] is measured by criteria that we would probably reject if the Soviets used them to justify their programmes". The US administration has proposed a new interpretation of the treaty that would allow testing of SDI components as long as they were not actual weapons.

The group recommends that SDI research should be refocused on more long-term "high-leverage" goals, including the problem of mid-course discrimination of warheads from decoys and that defensive research should have a near-term goal of preventing or responding to a Soviet break-out of the ABM treaty and preserving options for selective defences.

Canadian budgets cut

Sacrificing all for space effort

Washington

CANADIAN science, already troubled by an uncertain financial future, took another body blow when the National Research Council (NRC) said recently that it would trim $20.5 million from its $400 million budget for the fiscal year starting next April.Particularly painful to those affected is that much of the money being trimmed from basic research efforts is being ploughed into the Canadian space programme, in particular for Canadian participation in the US space station.

The government makes no bones about the fact that some research projects will have to be curtailed or eliminated to support the space effort. In the next five years, NRC expects to realize an additional $125 million for its space station activities, but in the short term it has had to find $14.6 million for space activities from its existing budget.

Ralph Nicholls, a space scientist at York University, Ontario, and chairman of the Canadian advisory committee for scientific uses of the space station, says it is unfair to blame NRC for implementing government science policy. Nicholls says Canadian space scientists have also been hurt by the government's decision to eliminate the rocket and balloon programme, and now Canadian scientists find themselves in the same boat as their counterparts in the United States, who are having to wait for space shuttle flights to resume before their scientific projects can start again.

Although the cuts fell relatively evenly among the major divisions of NRC — biological sciences, chemistry, electrical engineering, astrophysics, construction research, mechanical engineering, aeronautics and physics — perhaps no area feels the cuts more keenly than radioastronomy. Canada has two major radioastronomy facilities; the Dominion Radio Astrophysical Observatory at Penticton, British Columbia, and the Algonquin Radio Observatory at Algonquin Park, Ontario. Both are under the control of the Herzberg Institute of Astrophysics, itself supported by NRC.

Institute director Donald Morton says there were plans to refurbish the Algonquin Park observatory to let it operate at shorter wavelengths. But when it became clear that the necessary $10 million would not be forthcoming, and the institute's budget was being trimmed by $1.1 million, attention focused on the viability of Algonquin Park. Although Morton insists no decision about the observatory's future will be made until next spring, he admits that prospects are not good.

Paul Wesson, a radioastronomer from the University of Waterloo, believes a decision to close the Algonquin Park Observatory would make Canada a "non-competitor" in international radioastronomy. Even without the refurbishment, the observatory is the largest steerable-dish antenna in North America devoted solely to radioastronomy. The planned improvement would allow the telescope to operate in the 1.5–4 mm range, making it the second largest millimetre-wavelength observatory in the world.

Wesson worries that because radioastronomy does not provide readily appreciated benefits to society, it is particularly vulnerable to future cutbacks.

Optical astronomy has also been hurt by the NRC budget adjustment. Sidney van den Bergh last month resigned as director of the Dominion Astrophysical Observatory in Victoria when the latest round of cuts was announced. He says the Victoria observatory has shut down one of its three telescopes, mothballed its optical shop and cut its support personnel to the absolute minimum.

Also struggling is TRIUMF (the Tri-University Meson Facility) in Vancouver, British Columbia. Last spring, NRC informed TRIUMF that its annual operating budget of $28.1 million would be cut by $4 million. Half that money was restored when it became apparent that TRIUMF would default on international contractual obligations without additional funds, but a $24 million budget is likely for the next fiscal year.

Earlier this year, the three Canadian granting councils announced a unique scheme to encourage industry contributions to scientific research by matching private funds with government money (see *Nature* **320**,102; 1986). Industry's willingness to participate in the scheme has yet to be demonstrated, however.

The Canadian Minister of State for Science and Technology, Frank Oberle, has promised to produce a national science and technology policy. With no firm timetable for its completion, many policy changes may be in place before the minister's plan is presented to parliament.

For those in government science posts both in and out of Ottawa, morale has plummeted. Many fear the current cuts are merely forerunners of larger cuts in the years to come, as the government shifts responsibility for basic research to universities and industry.

The furore created by NRC's cutbacks has prompted Oberle to form an independent panel that spokesman Dave Dale says will review the "whole overall macro picture" of NRC's role in Canadian science. Trying to sound optimistic, one NRC official said that although the council may be "more than slightly hurt, it is not mortally wounded".

New chairman for vice-chancellors

Sir Mark Richmond to CVCP.

PROFESSOR Sir Mark Richmond, vice-chancellor of the University of Manchester, will become chairman of the UK Committee of Vice-Chancellors and Principals in July 1987 in succession to Mr Maurice Shock, vice-chancellor of the University of Leicester. □

Accord renewed

Washington

AFTER a five-year hiatus, Canada and the Soviet Union have signed an agreement to resume mutual academic, scientific and cultural exchanges. Canada suspended official exchanges in 1981 following the Soviet intrusion into Afghanistan. The new agreement takes effect at the start of next year, and will run until the end of 1988.

The Canadian move comes on the heels of a similar exchange agreement signed this past summer by the United States and the Soviet Union (see *Nature* 322, 491; 1986). Anton Yurkowich of the Ministry of External Affairs says Canada was the last member of the North Atlantic Treaty Organization to renew basic exchange agreements with the Soviet Union among those that suspended them after the arrival of Soviet troops in Afghanistan.

Yurkowich says the decision to renew formal contacts is not tied to any specific political change, but rather that "the time was ripe to get back to talk again". The Ministry of External Affairs has obtained budget authority for up to 27 individuals for academic and scientific exchanges, and is negotiating with the Association of Universities and Colleges of Canada to administer the programme.

The major beneficiaries will probably be Canadian Slavonic scholars who have been denied access to Soviet library and archive material. Assured access to archival material was also keenly sought by the United States in its accord. Joseph Palca

Hubble Telescope taking shape

TECHNOLOGISTS from British Aerospace have just returned from California where they have been helping engineers from the European Space Agency's Technology Centre (ESTEC) to install the solar panels for the Hubble Space Telescope.

The arrays, built by a consortium led by British Aerospace, had been delivered in May to the telescope's construction site at the Lockheed Missile and Space Company complex in Sunnyvale. The arrays, the first to be designed to allow astronauts easily to retract and dismantle them, are contained on two panels unrolled from a single drum composed of more than 48,000 solar cells covering 356 square feet.

The retractability of the arrays and their ease of manipulation are two fundamental features of the design, as the telescope will have a 15-year life expectancy, three times that of the panels.

The telescope, due to be launched in two years time, will orbit at 593 km, allowing it to make observations free from Earth's atmosphere. It is designed to look seven times deeper into space, detect objects 50 times fainter and view them with 10 times greater clarity than the best telescopes on Earth. The Hubble Telescope will carry five scientific instruments that are replaceable and serviceable in orbit. They are the Faint Object Camera (FOC), the Faint Object Spectrograph, the High Resolution Spectrograph, the High Speed Photometer and the Wide Field/Planetary Camera.

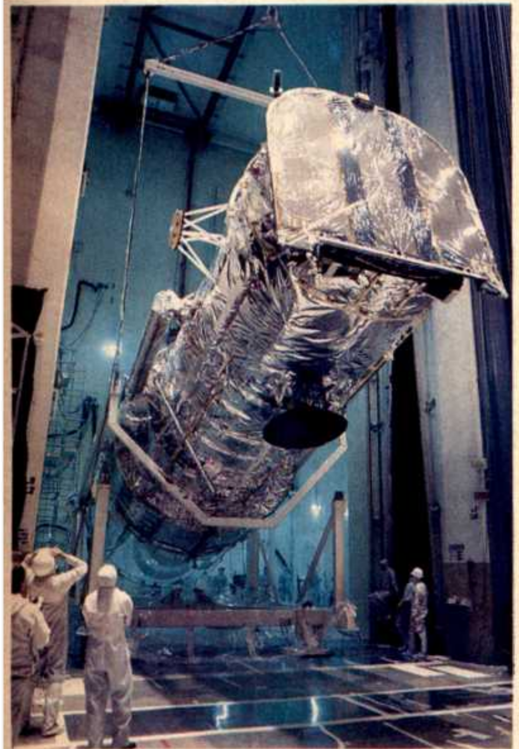
Hubble on test at Sunnyvale



Coral reefs

Okinawa runway under attack

Tokyo

THE battle to save one of the few thriving coral reefs left in Japan is about to reach its climax. The Okinawa prefectural government is expected soon to file a formal request with Japan's Construction Ministry to begin building an airport for jumbo jets on a reef of rare Pacific blue coral in Ishigaki Island, one of the southernmost islands of the Okinawa chain. Lined up to oppose the airport is an army of environmentalists from Japan and elsewhere.

The twin scourges of development and crown of thorns starfish (*Acanthaster planci*) have wreaked havoc with the coral reefs of the Okinawan Islands and the reefs of Ishigaki are rare remnants of what was once a thriving reef system.

Although Ishigaki already has an airport with a regular jet service to Okinawa, local government officials ten years ago proposed building a second airport with a longer 2.5-km runway to bring large jetloads of tourists direct from Osaka and Tokyo, and in 1979 the site of Shiraho lagoon was selected.

Shiraho was selected because a nearby hill (Karadake peak) could be razed and dumped in the lagoon to create a level area of 130 hectares, conveniently walled in by the outer reef. But the people of Shiraho town (population 2,000) are vehemently opposed to the plan.

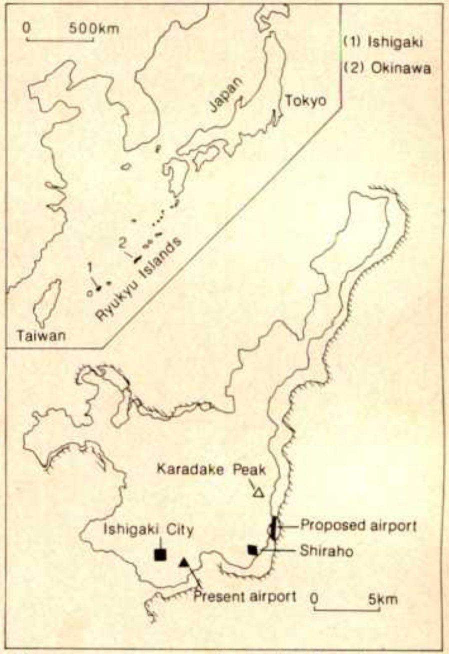
Two years ago, the Environment Agency planned a three-day survey of the reef. Local protesters tried to obstruct agency officials but were dissuaded by riot police and helicopters. Fearing further bad publicity, Ishigaki Town engaged Dr J. E. N. Vernon of the Australian Institute of Marine Science and Dr D. Kuhlmann of Humboldt University in Berlin to conduct a survey. But they were obstructed by Shoei Shirai, a local man appointed to help them, who later issued a report concluding that the reefs of north-west Ishigaki were the most valuable and the proposed site was not worth preserving. Vernon promptly disassociated himself from the report.

Vernon and other coral experts have been particularly struck by Shiraho's unusually extensive stands of Pacific blue coral (*Helipora cerulea*), a species listed under the Convention on International Trade in Endangered Species. Colonies tens of metres in diameter and 2-3 metres high stretch for hundreds of metres, constituting by far the biggest stands of this coral known in Japan.

In an attempt to allay concern, an informal advisory panel to the Governor of Okinawa that recommended construction of the airport has suggested that the coral be removed and 'replanted' elsewhere. But coral is not the only concern of opponents to the airport. Many have questioned the necessity of a second airport for such a small island, and there are fears that the 'spare' airport may be used for military purposes — Ishigaki is strategically placed at the southernmost tip of Japan.

Opposition to the airport is attracting worldwide attention. Last summer Jacques Cousteau wrote to the governor of Okinawa appealing for the plan to be dropped, and last month more than 500 environmentalists from Japan, the United States and the Philippines chartered a ship and called at Ishigaki to hold a protest rally on Shiraho beach.

In a ploy to delay construction, several hundred square metres of land needed for the airport apron that had slipped through the government buyer's hands were promptly bought up by the anti-airport group and sold off in doormat-sized lots to supporters. The government will now have to negotiate with about a thousand 'owners' to get the land back.



But the biggest obstacle for the airport planners is the fishing industry of Shiraho. Fishermen in Japan wield extraordinary power, and their consent must be won before construction projects affecting fishing grounds can go ahead.

Although the 600-member fishermen's cooperative of Ishigaki accepted Y500 million (£2 million) in 1980 as compensation for loss of fishing grounds at Shiraho, of which Y200 million was earmarked to pay off the cooperative's debts, the 30 fishermen of Shiraho have steadfastly refused to accept the agreement, and have taken their cooperative to court. As long as the disbursement of compensation remains blocked, airport construction cannot go ahead.

David Swinbanks

Yugoslavia

Serbian centenary "postponed"

SERBIA's Academy of Sciences and Arts, embroiled in a fierce political row with the authorities, has postponed the celebration of its centenary, due next week, until May. This decision follows fierce criticism by party and government leaders of an outspoken memorandum on the continuing social, economic and political crisis in Yugoslavia prepared by an academy group headed by Dr Antonije Isakovic, a vice-president of the academy. Under pressure, the academy has stopped work on the project.

Both the memorandum and the academy's decision to postpone its celebrations have been criticized. The Belgrade daily *Politika* on 23 October described the decision to postpone the celebrations as a kind of blackmail, and said that neither a handful of academics nor the president of the academy has the right to alter the date of the celebrations, which was "fixed by the history of its existence". *Politika* seems to have forgotten that, in 1974, the Soviet Academy of Sciences found it necessary to postpone the celebration of its 250th anniversary for a year.

The disputed memorandum deals with all aspects of Yugoslav life and presents a grim picture of bureaucracy, arbitrary decision-making, corruption, nepotism and a disregard for the law by those in positions of authority. Its advocacy of constitutional reform and the genuine participation of the public at large in decision-making has been attacked by the party theorists as anti-socialist, a betrayal of the legacy of Tito and evidence of a wish to break up the Yugoslav federation.

On education, though, the memorandum seems more concerned with keeping Yugoslavia together than with dismembering it. It castigates as divisive the present set-up in which each of the six republics and two autonomous provinces that constitute the federation has its own educational system (and academy of sciences). The memorandum says that countries without unified educational systems cannot expect to remain unified.

The memorandum also attacks a number of the educational concepts beloved of the party theorists, including that of "job-oriented" education, the result of which has been the over-production of ill-trained "specialists" unable to play a part in the social and economic life of Yugoslavia. It also says that the party campaign against elitism has meant a levelling down of standards and that the requirement that all persons employed in education should be "morally and politically suitable" has made the universities hot-beds of "careerism and conformity".

The Isakovic group also attacks the much-praised reform of the universities which hived off research into separate institutes, saying that the result has been the destruction of the laboratory base of the universities and the compartmentalization of science. The memorandum concludes that the universities therefore cannot play their essential part in the "technology-computer revolution". It advocates a thorough reorganization of scientific institutions in the interests of modernization, efficiency, greater financial investment and freer creativity.

Vera Rich

Ups and downs of French science budget

THE French research budget for 1987, up on the budget for 1986 as corrected after the present government came to power in April, but down compared with that planned for 1986 by the previous government, seemed to cause more excitement in the French National Assembly last week than any other aspect of next year's planned spending.

Leading socialist Jean-Pierre Chevènement was reportedly in fine form. His grand edifice of a ministry for research, technology and industry has been gradually dismantled, first by his own government (which trimmed off industry) and then by the present incumbents (technology has now gone, and the rump has been attached to the ministry of education). The ex-minister was exacting his revenge. He told the present science minister, Alain Devaquet, who is proud of his achievement in protecting the research councils and winning a modest rise in budgets against considerable internal opposition, that his budget was "faked and inflated". It was a "conjuring trick ... unworthy" of a sympathetic man like Devaquet.

The new minister rose to defend himself. The use of a single quantity, finance, was not the way to handle such a complex matter as French science, he said. Nevertheless, the national budget in government and industrial research and development would be up 8.5 per cent (on actual 1986 spending) to FF127,000 million (around £13,000 million), Devaquet claimed. A particularly big increase in defence research spending in the 1987 budget would offset decreases in support for industrial research in other areas. Criticized for this by socialists, Devaquet stoutly defended defence research: "I don't share the disdain of certain speakers for military research . . . It has done a great deal for many important industries."

However, André Giraud, the defence minister, will now have a research budget of FF30.8 million. Devaquet's budget for basic science is FF21 million. "So who is now the minister of research?" Chevènement taunted. Well, not M. Chevènement, anyhow . . .

Robert Walgate

X-ray astronomy

British–Soviet collaboration

A JOINT British–Soviet X-ray astronomy satellite may be launched in the early 1990s. Five British X-ray astronomy groups are now working out proposals for experiments to be submitted to the Soviet side at the end of December. If all goes well, the Soviet acceptance is likely to come by the middle of next year. The project, generated by a visit of a delegation from the British National Space Centre to the Soviet Institute of Space Research at the beginning of October, is viewed by both sides an important development. Dr Roald Sagdeev, director of the institute, said the meeting showed that Soviet and British scientists have good prospects for cooperation in space, especially in astrophysics, radioastronomy and the study of materials in space.

Until now, there has been relatively little direct cooperation between the two countries in space. The most significant project, so far, has been the British involvement in Roentgen, a module of four large X-ray telescopes to be mounted on the Soviet Mir orbital station next year.

But it was not the Soviet Union that initially proposed that Britain should take part but the Dutch, who wished to work in the hard X-ray/low-energy gamma-ray range using a coded-mask telescope, the principle of which was pioneered at the University of Birmingham. The first such telescope was flown on the Skylark rocket in 1976, and an improved version aboard Spacelab-2 in 1985. Professor Peter Willmore from Birmingham, who is now coordinating the proposals for the satellite, is reluctant to say too much about possible experiments. But the final proposal, he said, would be for a cluster of telescopes, using a variety of techniques to cover various energy bands.

The satellite, if all goes well, will be financed by each country paying for its own experiments and the Soviet Union covering the cost of the satellite and the launch. The project would therefore follow the normal financial pattern of Soviet collaborative projects, and has nothing in common with the purely commercial proposals, made by the Soviet Union in the wake of the Challenger disaster, that the Soviet Proton rocket could be used to launch satellites for foreign customers.

Vera Rich

Semiconductor rivalry

US bid to equal Japanese

Washington

THE beleaguered US semiconductor industry, hard pressed by superior manufacturing technologies from Japan, hopes to regain its competitive edge in world trade through a major cooperative manufacturing enterprise called Sematech. The Semiconductor Industry Association (SIA) will meet next week in Long Beach, California to give formal approval to the "manufacturing excellence project" that is already getting strong encouragement from US government.

Warren Davis of SIA says the industry's plight stems from the inability to develop effective manufacturing technologies for implementing innovative semiconductor designs. Davis believes no single US company is capable of taking on the scale of project needed for creating a new generation of manufacturing technologies.

Since early summer, representatives of the semiconductor industry have been holding discussions among themselves and with government officials on how best to proceed with Sematech. Some companies would like to see a full-scale manufacturing project, with the manufacturing muscle to beat the Japanese. Others would like a smaller pilot programme, with the technical fruits falling to individual companies. A compromise between the two approaches is likely.

Concern in Washington has been growing about the health of the US semiconductor industry, with several recent reports raising national security alarms over availability of semiconductor products (see *Nature* **323**, 483; 1986). Davis says if Sematech is to work, the government will have to give assurances that the effort will not be hindered by antitrust prosecution or unfavourable tax status. Referring to the Sematech project, Bruce Merrifield, assistant secretary of commerce for productivity, technology and innovation has spoken enthusiastically about the government's role as "the catalytic element of change", eliminating potential barriers to success. SIA officials were in Washington last week for talks with Merrifield and National Science Foundation (NSF) director Erich Bloch concerning Sematech. Although no government funds have been committed to the project as yet, commitments on taxes and antitrust issues could be worth millions of dollars. The Semiconductor Research Corporation, an industry supported consortium, recently received a grant worth $1.2 million from NSF and the Department of Defense, and could be a conduit for additional government funds.

Joseph Palca

Ozone depletion

US gets tough on CFC emissions

Washington

THE US government startled environmental conservatives and delighted radicals last week by calling for a complete halt to global emissions of halogenated alkanes thought to be destroying stratospheric ozone. The proposal was made in a paper on principles for an international protocol for protection of the stratospheric ozone layer issued by the State Department.

The United States will take the proposal as a starting position for the international negotiations beginning at Geneva on 1 December intended to put flesh on the bones of the Vienna Convention on Protection of the Ozone Layer. The convention has been signed by 25 countries since March 1985, but negotiations on a protocol to implement controls on chlorofluorocarbon (CFC) emissions have been postponed until the completion of informal technical meetings.

Anxiety about damage to the ozone layer, which filters out high-frequency ultraviolet radiation from the Sun, has grown in recent months. A 'hole' in the ozone layer appearing over Antarctica during the Antarctic winter (see *Nature* **321**, 729; 1986 and **315**, 207; 1985) is just now the subject of a study mounted by an inter-agency US team.

Although the cause of the 'hole' is not definitely known, the team's preliminary observations suggest that "a chemical mechanism is fundamentally responsible for the formation of the hole". Global ozone cover is thought to have decreased by 2–3 per cent in 1970–80, although measurements have been hard to interpret. CFCs also contribute to the greenhouse effect, by which the lower atmosphere may be warmed because of the effects of pollutants on the atmospheric radiation balance.

According to the State Department's proposal, a "long-term scheduled phase-out" of emissions should follow a near-term freeze on emissions of all fully halogenated alkanes. These include the widely used chlorofluorocarbons CFC 11, 12 and 113, believed to be the worst offenders, and halons 1211 and 1301. The proposal says that present uncertainties preclude the definition of a safe level of emissions, but that given the risks to health and the environment, the measures are justified. The proposed progressive reductions would be subject to change in the light of accumulating data.

The US proposal mentions in passing the need to develop incentives to persuade non-signatories of the convention to participate in the protocol.

The US industry group of chlorofluorocarbon manufacturers, the Alliance for Responsible CFC Policy, claims that the US proposal is not based on scientific principles. The alliance has proposed a cap on CFC production capacity and voluntary emission reduction measures to meet concern about the ozone layer.

The US proposal was based at least in part on a draft study by the Environmental Protection Agency, which estimates that incidence of skin cancer could increase significantly if emissions continue unchecked. But the industry alliance points out that the study has not yet been formally reviewed by the agency's scientific advisory board. A spokesman said that a phasing out of emissions did not necessarily mean an end to production, if some means could be devised to return CFCs to manufacturing plants for reuse.

Tim Beardsley

Deaths foretold

Washington

AN extra 40 million skin cancer cases and 800,000 deaths among people now alive and those born before 2074 are likely in the United States if CFCs are not further controlled, according to EPA's draft study* of stratospheric modification. The predictions stem from the expected increase in ultraviolet-B radiation reaching the Earth's surface as stratospheric ozone declines. The EPA study is largely responsible for the tough new US position on emission controls.

The predictions assume annual growth of 2.5 per cent for CFCs and 0.6 per cent for carbon dioxide, in line with current estimates. They also assume a continuation of present growth rates of nitrous oxide and methane (0.25 per cent and 1 per cent respectively). Equilibrium global temperature would under these conditions increase by between 3 and 9.5 degrees celsius by 2075, assuming the National Academy of Sciences' estimate of a 3 degree rise from a doubling of carbon dioxide.

EPA says that, as well as increasing skin cancers and cataracts, the increase of ultraviolet-B could promote the spread of herpes and leishmaniasis. There may also be effects on aquatic food chains and terrestrial plants, although information is scanty. But the study shows that estimates of risks are highly sensitive to CFC and halon growth rates; if the CFC growth rate is halved from 2.5 per cent to 1.2 per cent, estimated damage is reduced by 90 per cent. If a growth rate of 3.8 per cent is assumed, estimated damages increase by 400 per cent.

Tim Beardsley

An Assessment of the Risks of Stratospheric Modification (final draft), **submission to EPA Science Advisory Board, October 1986.**

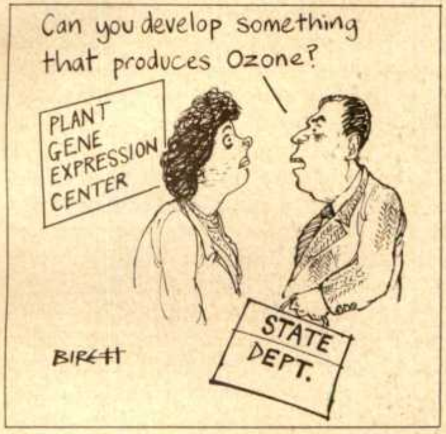
US agricultural research

Plant genes now fashionable

Washington

THE US Department of Agriculture (USDA), frequently criticized for its neglect of plant molecular biology, is now preparing to open a showcase institute with this theme at Albany, near San Francisco, California. The new Plant Gene Expression Center could herald a growth of interest from other government agencies.

At the outset, the new centre, under the aegis of USDA's Agricultural Research Service (ARS), will work on the transformation and regeneration of monocotyledons, the use of transposons to 'tag' and identify genes, molecular mechanisms of hormone action and environmental regulation of gene expression. USDA's annual support will be about $6 million, but extra funds will be sought from other sources.



Can you develop something that produces Ozone?
PLANT GENE EXPRESSION CENTER
STATE DEPT.
BIRETT

The scientific director will be Peter Quail, now at the University of Wisconsin. The centre will eventually house 10 research groups, some of whose leaders will also be professors at the nearby Berkeley campus of the University of California. Quail says the Berkeley link will be important; staff will be employees of the university, not civil servants, and visiting scientists will play a vital role. He hopes the centre will develop techniques for manipulating plant genes coding for informational molecules that will have long-term applications in crop improvement.

But while USDA is planning its own modest expansion of basic plant biology, the White House's Office of Science and Technology Policy is pushing for a more far-reaching increase in federal support. The view there (shared elsewhere) is that plant science has been eclipsed by the popularity of biomedicine, and urgent action is needed to redress the balance.

Indeed, the Office of Management and Budget hopes that there will be funds in the 1988 federal budget for an inter-agency initiative in basic plant biology . This proposal has been made by the Departments of Agriculture and Energy and the National Science Foundation and would support several new 'interdisciplinary research groups' in plant biology at universities, concentrating in five areas:

- microbial ecology and genetics in the rhizosphere
- chemistry of complex plant carbohydrates
- molecular biology and genetics of plant cells
- modelling of agro-ecosystems
- information technology.

Part of the impetus for the new initiative is the need to develop a 'predictive ecology' to help resolve the regulatory paralysis over environmental releases of genetically modified organisms. Whether those who hold the purse strings will support a major expansion remains to be seen.

Some academics are sceptical about the plan, saying that researchers can collaborate when they need to as things are and that the plan may simply be a way of dressing up a case for more money. Virginia Walbot of Stanford University believes that universities will find it hard to assemble true interdisciplinary groups without the promise of long-term support, which may be hard to get.

Peter Quail: aiming at better crops despite agricultural surpluses.

Others point out that the director of the Office of Science and Technology Policy, William Graham, whose support would be vital, has a background in defence, and may not be enthusiastic about biological research.

On a political level, the problems of US farmers are seen as stemming more from surpluses than from shortages, and biological research is seen — rightly or wrongly — principally as a way to make the surpluses bigger. **Tim Beardsley**

Grassroots unrest in plant biology

Washington

DESPITE the creation of the new Plant Gene Expression Center, seen by many as a belated attempt by (USDA) to jump on the plant biotechnology bandwagon, many academics believe research in basic plant biology has been seriously neglected.

The figures are telling; ARS's total budget will be $498 million this year, but that is all in-house and includes the cost of running laboratories. At least one-half is applied research such as plant breeding.

The Cooperative State Research Service, the USDA research arm which, jointly with state governments, supports the state experimental research stations, has a budget of $300 million, but only $40 million goes as competitive grants open to the university community. On one estimate, total federal support for innovative basic plant science open to competitive proposals from academics, including programmes of the Departments of Agriculture and Energy and the National Science Foundation, is only $110 million, compared with over $3,000 million spent on basic research by the National Institutes of Health in 1986.

ARS does support many small projects that use modern molecular biology techniques, but critics, such as Roger Salquis, president of Calgene Inc., and Stanford's Virginia Walbot agree it could have made better use of its opportunities. And the minuscule competitive grants programme, though increased in size in recent years. is not popular with academics; fewer than 10 per cent of proposals succeed, while grants (including overhead) vary between $50,000 and $80,000 in amount and last for only two years. Tim Beardsley

FRG–Soviet agreement

German deal put on ice

Hamburg

THE proposed agreement on research collaboration between West Germany and the Soviet Union seems to have been one of the first victims of the ill-feeling generated by Chancellor Helmut Kohl's controversial reference last month to Mr Mikhail Gorbachev, the general secretary of the Soviet Communist Party.

In an interview with the US news magazine *Newsweek*, Kohl had described Gorbachev as an "expert in public relations" and had likened him to Hitler's minister of propaganda, Josef Goebbels. Now Moscow has cancelled a visit during which Dr Heinz Riesenhüber, minister of research and technology in the federal government, was to have signed an agreement on the peaceful uses of nuclear energy and other matters reached only in July this year (*Nature* **322**, 488; 1986) after a decade of intermittent negotiation.

As things are, there is an exchange agreement between the Deutsche Forschung Gemeinschaft (DFG) and the Soviet Academy of Sciences but no agreement on scientific collaboration between the West German and Soviet governments. **Jürgen Neffe**

Remedy for British science

Sir—I agree with the spirit of your leading article (*Nature* **323**, 655: 1986) bemoaning the plight of British science, but I would question the political utility of the 'precepts' you urge the Advisory Board for the Research Councils (ABRC) to adopt to promote its case. In many ways they are all too familiar claims that those defending science have used in its defence. As such, they are as likely to be as unsuccessful in persuading Whitehall that its 'policies' — if that is not to dignify the disjointed initiatives of recent years too much — are damaging science as has been the more straightforward claim that 'we need more money'.

In many ways your precepts understate the real damage that is being done to the infrastructure of British science research. ABRC would be better advised, I believe, to make more of the wider national economic context in which science research and development finds itself, as well as to draw on what detailed information there is about the real damage that is being done to science at 'grass-roots level', the fundamental knowledge-generating culture of science.

On the first point, ABRC would do well to point out to its political masters that, according to the government's own Central Statistical Office, British industry, excluding oil, grew by only 1.5 per cent in 1979–85: little wonder that industry has had to look 'innovatory gift-horses in the mouth'. Moreover, where growth has occurred in the economy — in the financial sector — there appears to be little incentive on the part of financiers to invest in innovative research and development, basic, strategic or applied: money is best made out of money, on the financial markets.

At the more local level of laboratory life, my own research into the state of plant biotechnology and plant breeding in the United Kingdom reveals a failure by government to understand the research interests, abilities, needs and capacities for innovation of plant science. The speed and multidirectional nature of initiatives including privatization, rationalization and reorganization tend to pull (and literally so for its staff) science in opposite directions, breaking up the critical mass of research so vital to the future. Given the broader economic context sketched above, it is unlikely that scientific research and development is moving sideways into an expanding world of commercial opportunity. Management of science does need to be improved at national and local level: but clearly it can be effective only if it is informed by and sensitive to both.

Pressure to publish

Sir—Writing in your New Journals Review issue, Mary Holmes admirably summed up the problems we face with the ever-increasing range of specialized scientific periodicals available (*Nature* **323**, 359–360; 1986). A cause contributing to this information explosion is the extraordinary pressure on scientists to publish. This is certainly noticeable in the medical field, where appointments and promotions frequently hinge on the sheer number of papers published in reputable-sounding journals. (A letter to *Nature* might get more brownie points than a paper in *The British Journal of Controversial and Spurious Knowledge* but 70 papers are more likely to get you a senior lecturership than one seminal paper.) This puts pressure on scientists to subdivide pieces of research to produce a number of papers rather than one complete publication.

The recent attempts in Britain to assess the research worth of entire departments or institutions on the strength of five publications has not proved particularly happy, but I do not see why the abilities of an individual should not be assessed on the strength of half-a-dozen papers. If enough institutions changed that part on the back of their job application forms which says "Publications" to "List not more than six of your publications" the pressure on scientists would change to trying to produce a small number of very good publications. If this happened, a lot of semi-vanity publications would cease, and much material currently appearing in glossy print would be reduced to a footnote saying something like "Further details of this experiment are obtainable from the author on request" with no great loss to the flow of scientific information.

Scots elders

Sir—In the Opinion article "British science over the hill" (*Nature* **323**, 655; 1986), you say that three Scottish universities are more than 150 years old. The true figure is four: St Andrews (founded 1411), Glasgow (1451), Aberdeen (1495) and Edinburgh (1583).

A.M. Hetherington

113 Scotforth Road,
Lancaster LA1 4SD, UK

Isolated South Africa

Sir—*Nature* has a sound record (see **322**, 115; 1986) on human rights and freedom from repression for academics, but the conditions in South Africa would probably not have persisted if the grandees of the scientific community and the other learned academic communities had deployed their corporate influence against apartheid. In general, scientists and academics enjoy great prestige and privilege, and exert considerable influence within their own institutions. A large part of scientific research is supported by the public purse, either directly from government grants or from charitable foundations. It is not difficult for scientists to retreat into their laboratories until their research grants are up for renewal.

The cause of international scholarship is not more important than the fate and dignity of some 23 million black South Africans and five million white South Africans. One characteristic feature of the South African regime is its sensitivity to isolation. So long as South African athletes, diplomats, scholars and other professional and business people are granted free access to countries outside South Africa, especially the United Kingdom, Canada and the United States, the present regime in Pretoria knows that it will rule the Cape for a very long time.

The arguments against sanctions are based on previous experience when there was no common consensus for sanctions among the major European governments, Canada and the United States. There now seems to be a growing trend towards such a consensus.

Titles of references

Sir—I agree with John Maddox (*Nature* **322**, 681; 1986) that scientific literature is poorly written for the communication of the essential ideas of the research carried out.

One point he neglected to note is that a major contribution to this state is the obscure documentation of references. It is my opinion that a complete reference should always include the title of any cited work. I find this omission a great hindrance when researching related topics because I cannot determine beforehand whether an article is even remotely connected to my needs.

Unfortunately, I note that *Nature*'s reference style omits the titles of cited articles from journals. Your editors are contributing to this lack of communication as much as the authors.

How to tell when the sea rises?

Fears that, if the greenhouse effect is real, we shall drown rather than fry, require better ways of measuring sea level. There is a little progress to report.

THE present wave of interest in the linked problems of the atmospheric greenhouse effect and the integrity of the high-altitude ozone layer that spans the tropopause (see page 102, this issue) has also stimulated interest in what happens when the ice-sheets of Antarctica and Greenland begin to melt. Crude calculations of how mean sea level will be changed are easy enough. What we tend to overlook is that such a process would be novel only in degree, and that the consequences for the level of the oceans of the melting of the ice sheets of the last glaciation are still with us.

So much would have been plain to the participants in a conference on sea-level measurements and their interpretation held in Hawaii last year; some of the papers presented on that occasion have now been reprinted in the *Geophysical Journal* of the Royal Astronomical Society, and serve collectively as a reminder of the several influences that complicate the interpretation of the measurements, with all the complications arising from the need to distinguish mean sea level from the records of tidal gauges which are dominated by the variations due to solar, lunar and planetary tides.

It is remarkable, in the circumstances, that it has been possible to correlate changes of sea level along the south-eastern seaboard of the United States with the speed of the offshore Florida current, and mean sea level around the coast of Australia with a variety of oceanic and atmospheric phenomena, the Southern Oscillation linked with the El Niño phenomenon.

Obviously the time-span covered by a data set is crucial to the use that can be made of it. This is how it has been possible to infer, from tidal records around the margins of the North Sea, which parts of the coastline appear to be shrinking (the coast of England north of the Thames, for example) and which rising (the north coast of the Straits of Dover). But the statistical problems are formidable. People are looking for change of the order of 1 mm a year in data that may be distributed about the mean, after correcting for known seasonal variation, with a standard deviation of a few centimetres. Much of the incentive for the more detailed analysis of the effects of weather and ocean currents on sea level is the hope that it may, thereby, be possible to find meaningful signals in data sets that span shorter intervals. For what it is worth, those who believe that global warming may already be reflected in a steady rise of sea level suppose the magnitude of the change is approximately 2 mm a year.

That is why attention has also turned to the feasibility of direct synoptic measurements of movements of the Earth's surface topography of this order, where radio-interferometers on very long baselines (whence VLBI), already capable of measuring the distance across the Atlantic to within a couple of centimetres, are an obvious starting point.

W.E. Carter of the US Geodetic Survey (*Geophys. J. R. astr. Soc.* **87**, 3–13; 1986) seems to have explained to last years conference the accidental virtue of the US Defense Department's new navigation system (the Global Positioning System, which will have 18 satellites in three different orbital planes soon after the shuttle is in operation again) which has turned out to be a more convenient and cheaper version of VLBI. He offered the prospect that a sufficient density of suitable ground receivers, linked for accuracy with the VLBI network, should be able to monitor the level of tide gauges over reasonably short periods of time, less than a decade perhaps. But, rightly, people will first use this technique at the places where the surface level is changing much more rapidly; the post-glacial rebound of the area of the ex-Laurentian ice-shield (largely north of the Great Lakes) and Fennoscandia, where the change of level of the land surface approaches 10 mm a year (which is why the Great Lakes system is tilting towards the Mississippi Valley by rather more than 2 mm a year).

Another way of tackling the problem of direct measurement is to fix on some global quantity that can be measured accurately, and which depends somehow on the global sea level, so as to infer changes of the latter from measured changes of the former. What kind of quantity will fill that bill? The length of the day is obviously such a quantity, depending as it does on the moment of inertia of the Earth which in turn will depend on the mean sea level. The obvious difficulty is that there are many other influences on the length of the day, including both steady processes (such as the post-glacial rebound of North America) which progressively affect the Earth's moment of inertia, and dynamic processes (in the atmosphere or the oceans) which affect the Earth's rotation impulsively, and appear in the records as noise. How to distinguish all these factors?

Last year's symposium in Hawaii can have been left in no doubt of the difficulties after hearing the paper by W.R. Peltier, R.A. Drummond and A.M. Tushingham of the University of Toronto on the problem of post-glacial rebound (*ibid.* **87**, 79–116; 1986). Peltier is the one who, more than a decade ago, put the subject on a sound footing by showing that post-glacial rebound in North America and Scandinavia can be accounted for only by supposing that the present rate is controlled by viscous processes deep in the mantle of the Earth.

That is a curious tale. The Laurentian post-glacial rebound would not have taken 7,000 years if the compression caused by the loading of the ice had been a near-surface phenomenon. The calculations require that the effects of covering North America with ice would have been apparent 1,000 km or so beneath the surface, and that the rheology of material at that depth would imply a large viscosity. But in the past few years, it has emerged that that may be an illusion, one caused by what seems to be a phase transition at a depth of 640 km and which serves as a boundary through which influences cannot diffuse more quickly than the latent heat of the phase transition can escape.

For the once-glacial parts of the Earth's surface, the direction of sea-level change is determined by competition between isostatic rebound and the filling of the oceans with meltwater (which has long since ceased). In general, the changes involved are an order of magnitute greater than those now of interest — tens of metres per thousand years, not a millimetre or so each year. But much of the interest in Peltier's argument is that he is able to relate, for example, the changing topography of ice-sheets to the process of polar wander. Could it be that the best synoptic lookout for the predicted rise of sea-level after the greenhouse effect begins to bite will be a measurement such as that of the Earth's rotation poles?

Something of the kind is evidently necessary. The obvious indicator of global warming is the temperature of the Earth's surface, but that is even more complicated by noise (and incomplete coverage). But if the oceans act as a temporary sink for heat that would otherwise already be sufficient to make us over-warm, changing sea level might be the first indicator. **John Maddox**

Cytoskeleton

Dynamic microtubule dynamics

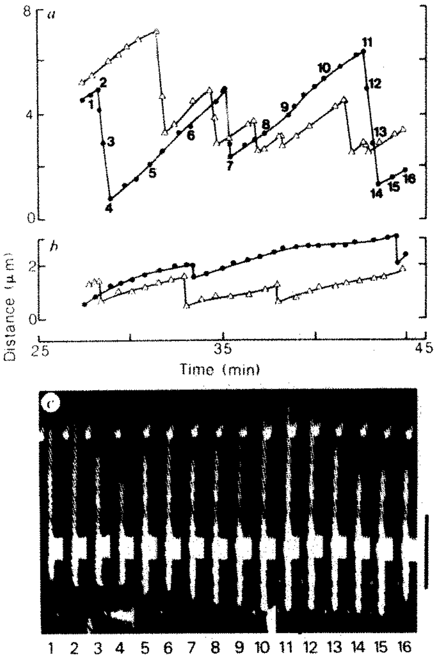
Robley C. Williams Jr, Michael Caplow and J. Richard McIntosh

WHEN assembly and disassembly of the microtubules from eukaryotic cells was first accomplished *in vitro* thirteen years ago, most observers thought the processes involved a simple reversible equilibrium between the polymeric microtubule and its tubulin subunits. Recent investigations reveal a livelier side of microtubule behaviour: an active growth and shrinkage of the polymer. A vivid example is the work of Horio and Hotani[1], who observed untreated microtubules *in vitro* in real time and found striking fluctuations in their lengths.

Microtubules in living cells come in all flavours of stability, from the ephemeral polymers of the mitotic asters to the sturdy stuff of which cilia and the protozoan cortex are constructed. Regulation of this diversity is, as yet, poorly understood, but it seems certain that the modes of microtubule assembly and disassembly lie at the heart of the matter. The assembly of tubulin subunits is accompanied by the hydrolysis of GTP. This reaction can produce a steady-state flux of subunits through the microtubule, a process termed treadmilling (see the discussion in *News and Views*[2]). Hydrolysis of bound GTP can, however, lag behind the incorporation of subunits[3]. The model that follows from this observation predicts the formation of inhomogeneous microtubules. In microtubules that are either growing or at a steady state of polymerization, the core of the microtubule is expected to consist almost completely of GDP-tubulin, whereas the recently added tubulin at the ends should form a GTP-tubulin cap[3,4]. Dissociation of a GDP-tubulin from the end of the exposed core is thought to be about 600 times faster than that of a GTP-bearing subunit from the cap[5]. Consequently, a microtubule is metastable: rapid disassembly results if the GTP-cap is destroyed (for example by dissociation of subunits from the end, by breakage, or by GTP-hydrolysis propagating endwards). According to this model, the macroscopic steady state of polymerization results from occasional rapid shrinkage of some microtubules, balanced by the slow growth of others.

This concept of microtubule behaviour was graphically supported by observations on the assembly of pure tubulin onto naturally occurring microtubule organizing centres[6]. Mitchison and Kirschner found that some of the polymers can shrink to disappearance while their immediate neighbours are growing. This phenomenon was presumed to occur via removal of subunits from, and addition to, the ends of the microtubule. Microtubules grown by elongation of preformed fragments also displayed a striking, simultaneous decrease in number and increase in the mean length of those remaining, both at steady state and on dilution. In the 'dynamic' instability model put forward to explain these observations, a given microtubule is in either a growing or a shrinking condition (phase), but is probably never static[7]. The relative rates of microtubule growth and GTP hydrolysis are thought to be the most significant factors in maintaining the GTP-cap[7]. (See ref. 2 for a discussion in *News and Views*.)

Is this model thermodynamically and kinetically sound? Is there perhaps some simpler alternative? The first question has been answered positively[8] in model studies that cast assembly and disassembly in terms of elementary reactions between soluble tubulin and plausible representations of the microtubule lattice. By choosing hypothetical values for the rate-constants, the model mimics the dynamic behaviour of microtubules in solution. The second question will not be as easily answered. Mitchison and Kirschner[6,7] explained the simultaneous increase in length and decrease in number of microtubules by an endwise, total disassembly of some polymers and addition of the released subunits to other, growing, microtubules. But immunogold labelling and electron microscopy studies[9] show that segments of preformed microtubules can also join together end-to-end to form a longer microtubule. This seemingly improbable but evidently quite efficient reaction, observed also with uncapped, taxol-stabilized, GTP-free microtubules (R.C.W. and M.C., unpublished observations), may contribute to the length redistributions on which the dynamic instability model is based.



Interconversions between the growing and shortening phases at the ends of a single microtubule. *a*, Length change at active end; *b*, change at inactive end; *c*, successive frame of a video image from one microtubule. (From ref. 1.)

Any doubt, however, that microtubules at steady state do fluctuate in length has now been dispelled by Horio and Hotani[1]. By means of real-time observation with dark-field optics, they can watch single microtubules change length (see figure). A given microtubule, when it is attached to the surface of a glass coverslip, can be followed through many cycles of shrinkage and growth. Their observations show directly that either end of each microtubule can exist in a growing or shrinking phase but that the length of a microtubule is never stationary. Micrometres of polymer, corresponding to thousands of subunits and perhaps 10–90 per cent of the length of a microtubule, assemble or disassemble between phase changes. The processes occurring at the two ends of one microtubule behave independently.

Not all these new results provide simple support for the picture developed by Mitchison and Kirschner[7,8], who explained the decrease in microtubule number and increase in microtubule length by asserting that the depolymerization phase would generally continue to completion, causing a microtubule to disappear from the population. Horio and Hotani's direct observation reveals no disappearing microtubules. Phase-reversal from shrinking to growth must be sufficiently probable, under the conditions of observation, to rescue essentially all microtubules from vanishing. One might think that this lack of conformity could be caused by the chamber used to make the observations. Attachment of microtubules to the glass surface might block their complete disassembly. But if this were the case, other microtubules not so close to the glass would disappear, thereby increasing the concentration of tubulin above that available at steady-state, so that the microtubules seen in the microscope would continually elongate. Because they neither disappear nor elongate, something other than simple dynamic instability must be going on.

Horio and Hotani also find, unexpectedly, that the end which undergoes more frequent reversals of phase, the 'active' end, grows and shrinks more rapidly than the infrequently reversing 'inactive' end. In current models, one imagines a GDP-bearing central region of the microtubule that gradually becomes longer as GTP hydrolysis proceeds on the incorporated subunits. At the active end, addition of GTP-bearing subunits should be more likely to outrun the spreading hydrolysis, leading to less frequent phase reversal than at the inactive end. It may be possible to reconcile the observed results with the GTP-cap model if GTP-hydrolysis occurs predominantly at the interface between the GTP-tubulin cap and the GDP-tubulin core (as suggested in ref. 10) and most rapidly at the active end.

Microtubule-associated proteins bind to the outside surface of microtubules, altering the energetics and kinetics of their assembly and disassembly. It seems likely that the GTP-cap persists in the presence of microtubule-associated proteins[5]. Yet when Horio and Hotani add these proteins to their microtubules, the frequency of phase reversal is greatly reduced. This result appears to be related to the observation[11] that microtubules containing microtubule-associated proteins do not show the length redistributions seen by Mitchison and Kirschner[6,7], but do undergo the treadmilling process. The function of microtubule-associated proteins in modulating the dynamic instability of microtubules thus may be physiologically important. This mechanism may, for instance, underlie the large, cell-cycle-dependent differences in lability of microtubules observed in photobleaching experiments with tubulin[12]. □

Natural selection

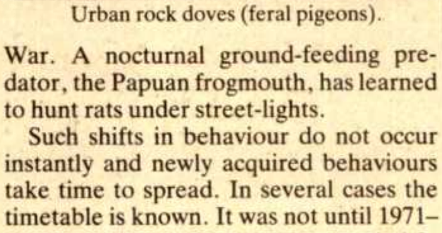
Rapid evolution of urban birds

Jared M. Diamond

A MAJOR dispute in evolutionary biology concerns the rate at which species evolve to occupy new niches. How suddenly did *Homo sapiens* replace *H. erectus*, and how soon after the demise of dinosaurs did large mammals arise? It is inevitably difficult to answer such questions using fossil evidence. Yet we live among many little-studied cases of rapid evolution, as species occupy habitats created by man. An example is the very recent formation of an urban avifauna in Papua New Guinea, summarized in a posthumously published paper by Harry Bell (*Proc. Western Fdn Vert. Zool.* **3**, 1; 1986).

In Europe, where towns have existed for thousands of years, many species of birds have become human commensals. Rock doves, starlings and house sparrows thrive in concrete habitats, and the latter species is now so closely associated with man that its original niche is unknown. In Papua New Guinea, however, the first town was founded a mere 112 years ago, and today only 16 towns have human populations exceeding 4,000. Typical town habitats are very unlike the New Guinea rainforest and consist of scattered trees and ornamental shrubs, mostly of introduced species. How quickly are bird species adapting to these new habitats, and what makes for a successful colonist?

In some cases the pre-adaptations are clear. The greater wood-swallow, which traditionally sallies from tall ridge-top trees over the primary rainforest, in towns sallies from radio towers and telephone poles. Shining starlings transferred their nests from holes in trees to vents of air conditioners, thereby becoming a pest. Swiftlets that would otherwise nest in caves now use tunnels excavated by the Japanese army during the Second World War. A nocturnal ground-feeding predator, the Papuan frogmouth, has learned to hunt rats under street-lights.



Frank Lane.

Urban rock doves (feral pigeons).

Such shifts in behaviour do not occur instantly and newly acquired behaviours take time to spread. In several cases the timetable is known. It was not until 1971–74 that a flock of black kites settled in the town of Lae to feed on road kills, although the town was founded in the 1930s. Only since 1983 have brahminy kites learned to feed on road-killed toads in Port Moresby. Goldie's lorikeet, which was formerly a rare species occurring in primary forest, arrived in the 1970s to feed on casuarina seeds in highland towns, where it is now the most abundant bird. Lemon-bellied flycatchers expanded from the savanna into the town of Wau between 1976 and 1978, 50 years after Wau was founded.

Checkered distributional patterns resulting from interspecific competition are common among closely related New Guinea bird species (my own work, in *Ecology and Evolution of Communities* eds Cody, M. & Diamond, J.M. p. 342; 1975). Bell's analysis of the town distribution of fruit doves (genus *Ptilinopus*) gives the first indication of how quickly the checkerboards develop. Three lowland species (orange-bellied, orange-fronted and pink-spotted) are each now resident in one or more towns, but no town except Popondetta supports more than one of the species, so that the distributions form a checkerboard. In natural habitats the orange-bellied and pink-spotted fruit doves are geographically widespread, the pink-spotted extends to higher elevations, but the orange-fronted is absent from the region that includes the towns of Lae and Madang. Town distributions are as follows: the orange-fronted is common in all lowland towns throughout its geographical range; the orange-bellied is found as a town bird only in Madang and Lae (and in Popondetta where it is less common than the orange-fronted and is possibly declining); and the pink-spotted occupies only Bulolo, above the altitudinal ceiling of the orange-fronted and orange-bellied. These results suggest that the orange-fronted has a competitive advantage in towns, that the orange-bellied succeeds only in the absence of the orange-fronted and that the pink-spotted succeeds only in the absence of both relatives. If so, this distribution must have arisen within the past 40 years and may not yet have reached equilibrium in Popondetta. There is a similar distribution in New Zealand, where two introduced starlings (the European starling and the Indian myna) have both acquired the habit of surveying pastures for food while perching on the back of a sheep, but in any given pasture only one of the two species occupies the sheep.

The successful town colonists are unrepresentative of the New Guinea avifauna as a whole in their preferences among natural habitats. Of species present in natural habitats near towns, only 4 per cent of the rainforest species but 33 per cent of the savanna species and 50 per cent of the second-growth species occupy towns. These differences partly reflect the varying similarities between the natural habitats and town habitats (least like rainforest), partly the behavioural plasticity of second-growth species. The very low success of rainforest species has grim implications, because it means that spreading urbanization will threaten New Guinea's famous rainforest avifauna.

As Bell notes, New Guinea town avifaunas are still far from the equilibrium that now exists in Europe. Changes in behaviour and status are occurring rapidly. The species/abundance relation remains unusually equitable: many species are vying for space in New Guinea towns, in contrast to the pattern of a few dominant species in older towns in other countries. This panorama of biology in rapid flux provides opportunities for field biologists to address some basic questions. Does the sudden acquisition of new behaviour depend on a genetic change or on culturally transmitted learning? How quickly does morphological and physiological evolution occur among colonists of the new habitats? We know that house sparrows living in wet or dry and hot or cold areas of North America differed morphologically when studied a century after their arrival (Johnston, R.F. & Selanders, R.K. *Science* **144**, 548; 1964) and that the advance of house sparrows in tropical Australia halted for 60 years before their final surge across the Tropic of Capricorn. Biologists neglected those and innumerable other opportunities to study natural selection in action. Such opportunites still exist in New Guinea and elsewhere. ☐

Jared M. Diamond is Professor of Physiology at the University of California Medical Schoool, Los Angeles, California 90024, USA.

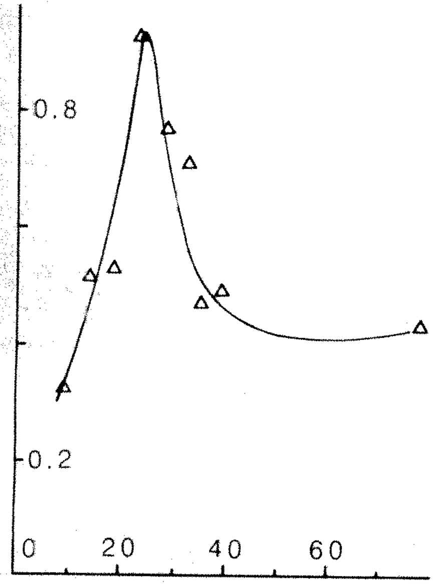
Metallic superlattices

The supermodulus syndrome

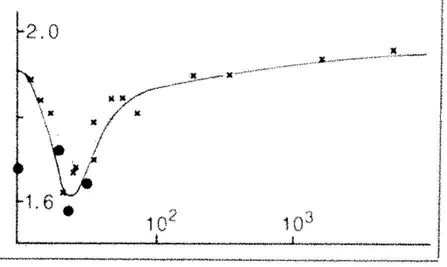
Robert W. Cahn

SYNTHETIC compositionally modulated epitaxial semiconductor structures, or semiconductor superlattices, were first proposed by Esaki and Tsu in 1969. Because of their remarkable electronic and optical properties, these structures have been investigated intensively since then. The metallic equivalent of semiconductor superlattices, synthetic modulated metal films, began to excite interest in 1977, but until now studies on these films have been scientific rather than technological. Recent work has succeeded in using synthetic, bimetallic modulated films for the spectral analysis of X rays[1], the investigation of extremely low diffusivities of one metal in another[2,3] and the study of phase transformations[4].

In 1977, Yang *et al.*[5] prepared a series of multilayer films of the metal pairs Au–Ni and Cu–Pd. The elastic stiffness of the films was measured by a primitive method that allowed the film to bulge under gas pressure over a small hole; the bulge height is determined as a function of gas pressure. The stiffness thus measured is a biaxial modulus. For Au–Ni the stiffness doubles for a critical thickness near 2 nm; for Cu–Pd, the effect is less pronounced. Recently, Baral *et al.*[6] used a more conventional, vibrating-reed approach to measure Young's modulus. The figures show their results[7] for Cu–Ni of constant 50/50 Cu/Ni ratio but varying periodicity and, for comparison, results with measurements of surface-wave velocity for 50/50 Cu–Nb films. The elastic anomaly near 2-nm thickness can evidently be a maximum or a minimum, although taken together, all published measurements[8] indicate that the anomaly is usually an enhancement and only rarely (to adopt the latest neologism) a dehancement. In Cu–Au films, however, there is no change. In some of the systems that show a modulus peak at a critical periodicity, there is also a peak of critical stress for plastic deformation.



Left, Variation of flexural modulus (in TPa, vertical scale) with wavelength (in Å, horizontal scale) for Cu–Ni. Below, Surface-wave velocity ($\times$ 10^5 cm s^{-1}, vertical scale) of Nb–Cu superlattices as a function of bilayer thickness (in Å, horizontal scale).



There are two main rival theories that seek to interpret this 'supermodulus' effect. Clapp[9] proposed a purely electronic interpretation in which the compositional modulation creates additional Brillouin zones which can touch the Fermi surface and thereby stabilize the modulated structure. If this happens, then an elastic strain will tend to drag the zone and Fermi surface out of contact, which acts in the direction of structural destabilization and thereby enhances the stiffness. (The converse effect is also conceivable.) As various theorists have pointed out (for example, ref. 10), this hypothesis predicts several critical periodicities that should lead to anomalously enhanced (or dehanced) stiffness.

The alternative view[11] is that the supermodulus effect is caused by coherency strains at the metal/metal interfaces, which are postulated to displace atoms so far from their normal sites that they are no longer within the hookean parts of their interaction potential. This approach can also interpret both enhancements and dehancements, but cannot explain the origin of the sharpness of the maximum so easily. For large periodicities, interface dislocations tend to form and release the coherency strains, but this still leaves unexplained the behaviour at periodicities of less than 2 nm. One interesting possibility is that the dehancement of stiffness in Cu–Nb films might result from glass formation by interdiffusion, the so-called solid-state amorphization reaction[12]. Cu–Nb would be a reasonable candidate system for this process, though it has not been investigated with the amorphization reaction specifically in view. It is interesting that Lin and Spaepen[13] find that in Ni–Nb multilayer films, metallic glass is formed spontaneously during film deposition (that is, without anneal) for layer thicknesses smaller than 3 nm.

Very recent work using Cu–(Ni,Fe) multilayers[14] shows the existence of a minimum grain size (~0.1 μm) at 2.6-nm periodicity. At this periodicity, the structure is seen to be defect-free; at smaller periodicities, partial interdiffusion reduces the sharpness of the interfaces and allows grains to coarsen; at periodicities greater than 2.6 nm, interfacial dislocations reduce the elastic coherency strains. These mechanisms can account for the modulus maximum at 2.6 nm. In other recent work[15], elastic moduli are calculated on the basis of the coherency strain model for Cu–Au and Cu–Ni multilayers as a function of periodicity distance, and roughly agree with experimental values

The debate between the electronic and coherency strain hypotheses (see refs 8,11) remains wide open, but it does increasingly look as though the coherency strain model will turn out to be correct

No practical use has been made yet of supermodulus enhancement, but the situation may be about to change Stiffness is a major concern in the development of improved aircraft alloys, and Al–Li and Al–Li–Be alloys, which are stiff and light, are now receiving concentrated attention A very new approach is to make massive aluminium alloy pieces, large enough to machine wing spars, by sequential evaporation[16] such alloys have substantially enhanced flow stress as well as stiffness, but there has been no report of a supermodulus effect at critical periodicities In any case, the periodicities used were 30–40 times larger than in the thin-film work, where peaks in flow stress have been observed at $\sim$2 nm periodicities[15] It remains to be seen whether alloy pieces of useful size can be made with perodicities around 2 nm, and whether an aluminium-based system will show the supermodulus effect Yahalom[17] has just reported a very promising new approach to making nanometre metallic multilayers by pulsed electrodeposition, applied initially to the Cu–Ni system He specifically suggests applying his method to the production of springs □

Molecular evolution

Deciphering divergent codes

L A Grivell

To evolutionary biologists the protists must appear a motley collection of organisms with diverse characters, defying simple classification, and with many unusual features whose original selective advantage can sometimes only be guessed at The discovery last year[1-5] that ciliate protozoa make use of an unusual version of the genetic code, in which UAA and UAG codons specify glutamine instead of stop is entirely in character and it offers molecular biologists a unique opportunity to piece together events in early evolution that may have led to the appearance of the present-day genetic code Clues to what may have happened are presented in a recent article by Hanyu *et al* [6]

Until 1981, the genetic code was believed to be the same in all organisms and it was therefore quite reasonable to assume that it had been fixed before the divergence of all life forms, any changes being impossible because they would make nonsense of messages for existing proteins This belief was shaken by the finding[7] that different versions of the code are used in the mitochondria of different organisms and that some of these changes must be of relatively recent origin

The simplest explanation for this extraordinary degree of genetic tolerance within mitochondria seems to be that only a limited set of proteins are encoded that function entirely within the hydrophobic environment of the inner mitochondrial membrane Mutations leading to changes in codon assignment, which would be lethal in a more complex genetic system with a wider range of gene products, are apparently acceptable This may also hold for the simple prokaryote *Mycoplasma capricolum,* in which, as in many mitochondria, the stop codon UGA is used to specify tryptophan (see ref 5 for a review)

How does the deviant code in the ciliates fit this picture? Are these organisms like mitochondria in being able to absorb changes in their genetic dictionaries, or are we looking at a relic of a primitive genetic code, one which possibly preceded the emergence of the so-called universal code? The first alternative seems unlikely in the light of the complex and definitely eukaryotic characters of the ciliates The second, in its simplest form, would seem to require that all bacteria, plants, fungi and animals have independently but consistently switched UAA and UAG codons to signal stop Hanyu *et al* [6] suggest a possible solution to this problem

These authors show the occurrence in *Tetrahymena* of three different transfer RNAs that can attach glutamine The first has the anticodon UmUG (m indicating methylation), capable of decoding the two normal glutamine codons CAA and CAG and is probably the counterpart of the glutamine-specific tRNA present in other organisms The others are unusual and consist of a $\text{tRNA}^{\text{Gln}}_{\text{UmUA}}$ and a $\text{tRNA}^{\text{Gln}}_{\text{CUA}}$ The first of these recognizes both UAA and UAG in natural messenger RNAs in an *in vitro* protein synthesizing system, while the second recognizes UAG only Sequence comparison shows that all three tRNAs are related, with $\text{tRNA}^{\text{Gln}}_{\text{UmUA}}$ and $\text{tRNA}^{\text{Gln}}_{\text{UmUG}}$ showing 81 per cent homology and $\text{tRNA}^{\text{Gln}}_{\text{UmUA}}$ and $\text{tRNA}^{\text{Gln}}_{\text{CUA}}$ 95 per cent homology Hanyu *et al* therefore conclude that the two unusual glutamine-specific tRNAs evolved from the normal one early in ciliate evolution by gene duplication and divergence, with the UAG-specific $\text{tRNA}^{\text{Gln}}_{\text{CUA}}$ derived from the $\text{tRNA}^{\text{Gln}}_{\text{UmUA}}$ to give a strengthened response to UAG

They go on to argue that because, apart from mitochondria and *Mycoplasma,* all eubacteria and eukaryotes normally use UAA, UAG and UGA as termination codons, it is more likely that two of these codons failed to specify termination during the evolution of the ciliates, rather than being acquired as stop codons by the other organisms in a process of convergent evolution They therefore propose that although UAA and UAG were probably stop codons in the archetypal ciliate, they must have been rarely used and that weak suppressor tRNAs for these codons may have existed at a very early stage Mutations creating UAA and UAG codons within protein-coding genes would not have been lethal for such prociliates Any subsequent mutation which allowed acquisition of an anticodon capable of perfect recognition of these codons would then result in the fixation of their use as amino-acid codons A G-to-A transition in the anticodon of a duplicated glutamine-specific tRNA gene is one of the simplest ways in which this could have occurred

This picture has some attractive aspects First, it is consistent with the suggestion by Woese[8] that the primitive genetic code may have been highly ambiguous and error-prone and that even though considerably fewer than the present 20 amino acids may have been encoded, it would have been important to minimize the number of codons not specifying an amino acid Second, it is consistent with molecular phylogenetic data[4,9] indicating that the ciliates branched off from the primitive eukaryotic ancestor very early in evolution, quite possibly at a time when protein translation was still tolerant of changes in the genetic code Finally, it is consistent with more recent patterns of change in evolution, in which gene duplication followed by the acquisition of a new function by one of the duplicated genes is common Despite these attractive features, however, the process proposed by Hanyu *et al* [5] tends to underplay the fact that many other organisms are able to recognize and translate termination codons which are used either to modulate the synthesis of certain proteins, or to allow the insertion of modified amino acids (for reviews, see refs 10,11) Recognition of termination codons *per se* is thus not unusual How they are recognized depends on subtleties of tRNA structure, modification or codon context The usage of UAA and UAG as normal codons in the ciliates may be an extreme form of this recognition process, perhaps one that has developed secondarily as part of the peculiar life style of these organisms

If, on the other hand, the existence of tRNAs capable of the recognition of stop codons is the relic of an intrinsic property of a primitive and error-prone code, additional variations in the code in other evolutionary groups might be expected, particularly in those subject to similar evolutionary pressures and who branched off the main eukaryotic line either before or around the same time as the ciliates Based on sequence comparisons of ribosomal RNA (ref 9), *Dictyostelium, Euglena* and the *Trypanosoma* represent even earlier divergence points from the mainstream of eukaryotic descent But neither *Dictyostelium* nor *T brucei* shows any deviation from the standard code Data on *Euglena* and other ancient groups, such as the dinoflagellates, the red algae and *Pelomyxa,* are eagerly awaited

Finally, a couple of other intriguing questions remain The first relates to the mechanism by which protein synthesis is terminated As Hanyu *et al* [6] point out, higher eukaryotes seem to use only one release factor for all three termination codons It will therefore be of interest to see how the *Tetrahymena* factor, which should recognize only UGA, differs from its known eukaryotic counterparts The other question is whether any organism exists or has existed in which stop codons are not used at all, so that translation is ended by 'run-off' synthesis It may be worthwhile to delve further among the protists, the answer could be in there somewhere □

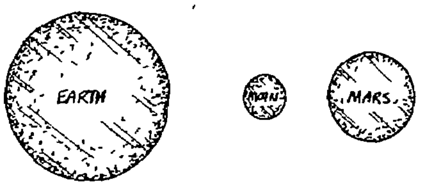
Cosmogony

Moon's birth shocked Earth?

Alan P Boss

THE most promising explanation of the birth of the Moon is the impact of a Mars-sized body with the Earth during the final phase of planetary accumulation If such an impact occurred nearly tangentially, the high angular momentum of the Earth–Moon system can be understood, one of the major attractions of this theory The first detailed computer simulations of such a giant impact have now been completed[1] and can be compared with lunar and geochemical data[2] to help isolate the manner in which the Moon may have formed

Thinking on the origin of the Moon has undergone a remarkable transformation in the past few years[3] Recent work on the three classical hypotheses of fission, capture and binary accretion has uncovered flaws in their mechanics serious enough to warrant their rejection But at the same time a relatively new hypothesis has become (not entirely coincidentally) quite popular This hypothesis invokes the collision of a Mars-sized or larger protoplanet with the growing protoearth[4,5], followed by formation of the Moon in Earth orbit from the debris of the explosion



Collision at 10 km s^{-1} of a Mars-sized body with the protoearth would produce a colossal explosion that may have led to lunar formation

When originally proposed a decade ago, the giant impact hypothesis received little attention, largely because giant impacts were thought to be highly improbable But a new variant of the general theory of terrestrial planet formation predicts that the final phases of formation primarily involved the accumulation of bodies ranging from about the size of the Moon (around one-hundredth the mass of the Earth) to three times the mass of Mars (three-tenths of the Earth)[6] The appearance of a general theory which predicts the occurrence of Mars-sized impacts on a protoearth of around the present Earth mass with essentially unit probability, coupled with the apparent demise of the competing theories, has encouraged serious efforts at exploring the consequences of the giant impact hypothesis

Benz and his colleagues[1] use a computer code to model the detailed physics of giant impacts much more accurately than previous efforts[7] The outcome of a giant impact depends sensitively on impact parameter (the offset between the centres of the colliding bodies) and relative velocity Small impact parameters require high relative velocities to achieve the angular momentum of the Earth–Moon system Benz *et al* found that small impact parameters lead to complete disruption of the impactor and to accumulation of this impact ejecta by the protoearth Their favoured model involves a large impact parameter where the impactor grazes the surface of the protoearth, survives the collision largely undispersed and quickly reforms into a cohesive body The protomoon is trapped in Earth orbit by a combination of dissipation of relative velocity during the collision, acceleration by gas pressure gradients in vaporized phases, and gravitational torques with the deformed protoearth Because the orbit of the protomoon initially has a perigee within the Roche limit of the Earth (around three Earth radii), the protomoon may eventually be tidally disrupted, forming a de-volatilized disk of matter which may accumulate into the final Moon More recent calculations by Benz *et al* include iron cores in both bodies, and show that the iron core of the impactor can be swallowed by the protoearth, leaving the impactor mantle to form the protomoon

These models illustrate the main successes of the hypothesis giant impacts provide a reasonable mechanism for injecting roughly a lunar mass of matter into Earth orbit, with the right amount of angular momentum, and with the matter depleted in iron and volatiles, as required by chemical analysis of lunar samples Furthermore, an origin as violent as proposed seems consistent with the large-scale melting required by lunar magma ocean models

One difficulty with this version of the giant impact hypothesis is now apparent Ringwood[2] has re-emphasized the strong similarities in abundance of siderophile elements in the Earth and the Moon The models of Benz *et al* imply that the protomoon formed almost entirely out of the impacting body, thereby requiring the impactor, formed elsewhere in the terrestrial planet zone[6], to have a mantle very close in composition to that of the Earth This improbable requirement spoils the beauty of the hypothesis But there may be a way out

Melosh and his colleagues[8,9] have also produced detailed models of giant impacts Contrary to Benz *et al* , they find that large-scale vaporization accounts for the formation of a prelunar disk about the Earth The discrepancy appears to be caused by different assumptions about the equation of state and by difficult numerical techniques, with the work by Melosh *et al* probably coming closer to reality Because vaporization does not discriminate between impactor and impactee, Melosh's prelunar disk is a roughly equal mixture of impactor and protoearth Making the Moon out of a mixture of impactor and protoearth mantle seems to solve the siderophile problem, because the protoearth composition would also be altered by the addition of the bulk of the impactor, with the final Earth mantle being composed of as little as about 70 per cent protoearth mantle (assuming a three-tenths Earth-mass impactor striking a seven-tenths Earth-mass protoearth), a proportion closer to that of Melosh's prelunar disk

Clearly many details remain to be investigated and other problems, such as giant impacts totally melting the Earth and producing a massive crust incompatible with the present Earth, will require explanation If divining the origin of the Moon were a paying proposition, venture capital firms would certainly be well advised to invest in improved models of giant impacts ☐

Fusion energy

Highest temperatures yet

R S Pease

DEUTERIUM gas in the Tokamak Fusion Test Reactor at Princeton was heated this summer to a temperature of 230 × 10^6 K (20 keV), perhaps the highest temperature yet recorded in a laboratory[1,2] It lies close to the temperatures planned for fusion reactors, and paves the way for the planned production of megawatts of fusion power in deuterium−tritium experiments in 1989 These promising results bring us closer to the goal of controlled nuclear fusion energy

What does this experiment amount to, and how does it relate to other attempts? The Tokamak Fusion Test Reactor experimental assembly is a toroidal electric discharge in a strong longitudial magnetic field Three other large tokamaks are now operating the Joint European Torus at Culham, JT-60 at Tokai in Japan and D III-D at San Diego In the Tokamak Fusion Test Reactor, the torus major radius is 2 4 m and its minor radius is about 1 m The discharge current in the high-temperature experiments is about 1 MA and lasts about 5 s, this current provides the magnetic field which confines the high-temperature deuterium plasma and provides the necessary thermal insulation, it also provides a relatively small amount of heating which on its own heats the plasma to about 20×10^6 K The higher temperatures at Princeton were obtained with considerable additional heating provided by injecting into this plasma a stream of energetic neutral deuterium atoms (pre-accelerated as ions to 95 keV and then neutralized)

The additional heating amounted to 17 MW for up to 0 5 s during the latter half of the current pulse, it raised the ion temperature at the centre of the discharge to 230 × 10^6 K This temperature was still rising at the end of the heating period (which is limited by engineering technicalities) The ion number density in the central region (within roughly 20 cm of the centre of the minor cross-section) is of the order of 5 × 10^{19} m^{-3}, and the thermal coupling between the electrons and the ions is relatively slow The electron temperature is about 70 × 10^6 K, noticeably lower than that of the ions The ion temperature was measured by the Doppler broadening of line radiation from nickel and iron impurities (in highly stripped, lithium- and helium-like states), and is consistent with magnetic measurements of the total energy in the plasma (roughly 2 MJ) The energy confinement time, a measure of the thermal insulation obtained by dividing the plasma energy by the input power, is between 0 1 and 0 2 s

The experimental error of the estimated deuterium ion temperature has not been announced, it is probably of the order of 25 per cent, but until a full exposition of the estimation methods is published, some reservation must remain on the value of the temperature quoted The temperature planned for in reactors is about the 230 × 10^6 K (or 20 keV) now claimed No such uncertainty applies to the deuterium–deuterium fusion power in the plasma, which is unambiguously obtained by measuring the neutron flux emitted from the plasma This fusion power is reported to be about 10 kW A substantial but unspecified proportion of this power must be due to direct interaction of the injected 95-keV deuterons with the plasma deuterons, an enhancing effect explicitly sought in the objectives of the Tokamak Fusion Test Reactor If a 50/50 mixture of deuterium and tritium had been used in the same conditions, then the fusion power would have exceeded 1 MW Previously about 0 5 kW of deuterium–deuterium fusion power has been reported from Princeton[3]

The achievement of these results primarily arises from the heating power — the largest yet used on a tokamak As reported both by Princeton and by the Joint European Torus team at a recent symposium[4], neutral injection is an effective way of heating large tokamaks to the 10 keV range, but is nonetheless accompanied by some degradation of the thermal insulation obtained without it, and a consequent two-fold reduction of the energy confinement time, depending on the power used An encouraging feature of the Princeton result is that this degradation has not increased at the higher power used The best heating was obtained using so-called balanced injection that is, the angular momentum imparted to the plasma by the injected deuterium atoms (which, in the unbalanced case, causes the plasma to rotate at near-sonic speeds) is kept small

From the point of view of scientific understanding, the key issue of the magnetic thermal insulation remains The energy losses from the plasma exceed the unavoidable minimum values arising from ion–ion collisions and from the inevitable bremsstrahlung radiation of hot electrons But in some conditions, and in some other experiments, these minimum values have been approached rather closely One encouraging indication given by the Princeton result is that a qualitative characteristic of the ideal thermal insulation, the bootstrap current[5], in which the collisional outward diffusion of the plasma across the magnetic field can by itself sustain the discharge current, has been indicated in some conditions of their reactor

Overall, the preliminary report from Princeton indicates the achievement of conditions close to those hoped for when construction of the $300-million apparatus was approved in 1976, and suggests that fusion power in the megawatt range is achievable in the planned deuterium–tritium experiments The report gives an encouraging foretaste of the results from experiments on all the large tokamak assemblies ☐

Mass extinctions

Catastrophic vegetation changes

Margaret E Collinson

DINOSAURS and ammonites are probably the best-known examples of the many species that became extinct at the Cretaceous–Tertiary (K–T) boundary[1,2] Because there are unusually high concentrations of iridium in the clays at the boundary, it is possible that the biotic changes were caused by asteroid impact[3,4] Terrestrial phenomena such as vulcanism may, however, have been responsible for the extinctions[5–7] Although ecological disruptions of marine biota at this time are widely documented[1–6], little is known about the influence of the K–T event on terrestrial species[8] New evidence from fossil land plants (refs 9, 10 and page 148 of this issue[11]) reveals a widespread ecological trauma, coupled with floral turnover, which occurred at the same time as the marine disruptions

Late Cretaceous floras were dominated by flowering plants in at least four distinctive floral provinces[12,13] In the Northern Hemisphere the Aquillapollenites province includes eastern Siberia and western North America, and the Normapolles province included Europe and eastern North America In the pollen and spore record several features characterize the K–T event There was a major floral turnover in the Aquillapollenites province, with extinction of many forms, more restricted turnover in the Normapolles province, but little or no turnover in Southern Hemisphere provinces A marked increase in the development of modern pollen types occurred in the early Tertiary[8,12,13]

The first detailed evidence of the vegetational expression of these floral changes, the 'fern spike', was found during a study of the K–T boundary in the Raton Basin of the western interior of North America[14] Destruction of pre-boundary angiosperm-dominated vegetation was followed by establishment of a fern-dominated, coal-forming mire vegetation Many Cretaceous flowering plants became extinct, although some persisted across the boundary Re-establishment of angiosperm dominance followed "within a few centimetres of the boundary"[14] but with very different floral composition

These events are known to have occurred throughout the western interior of North America and in Canada[9] Floral change in angiosperm groups falls into three categories major extinctions but with some species persisting across the boundary, groups showing evolutionary changes between pre- and post-boundary forms, and groups largely unaffected at the boundary In the first group, different species become extinct in the northern and southern parts of the region, and macrofloral analysis[11] reveals differential extinction in the southern (up to 75 per cent of Cretaceous species) compared with the northern (up to 25 per cent) part of the western interior The presence of a post-boundary, fern-dominated, coal-forming, mire vegetation was confirmed by the macrofossil analyses

A recent palynological study[10] from a marine sequence in Japan reveals a fern spike at the same time as the major faunal turnover in marine biota This study not only extends the geographical range over which the ecological disruption in the Aquillapollenites province has been recognized, but demonstrates, for the first time, that the marine and terrestrial events happened at the same time

A relationship between leaf form and prevailing conditions has been observed, where vegetation is in equilibrium with climate Using this relationship, Wolfe and Upchurch[11] report in this issue additional aspects of the K–T boundary events in western North America These include an increase in precipitation across the boundary with the initiation of rain forest environments in the early Tertiary, little overall change between late Cretaceous and early Tertiary temperatures, and a high survival rate of deciduous versus evergreen taxa across the boundary both in northern conifer-dominated and in southern angiosperm-dominated vegetation An increase in coniferous elements in the post-boundary vegetation occurred in the Montana/Wyoming area of the western interior of North America[11] and also in Japan[10] (It may also occur in the western Mediterranean if magnetostratigraphic correlation of the sections studied proves correct[15])

Vegetational changes across the boundary have been compared with the destruction and renewal of modern vegetation after catastrophic volcanic eruption[14,16,17] Replacement climax vegetation may, in such cases, be controlled by the disruptive effects of continued disturbance, without reaching equilibrium with the prevailing climate[18] Thus, palaeoclimatic inferences based on K–T boundary vegetation sequences assume that no subsequent disturbance affected post-boundary vegetation succession Sedimentological or other evidence is needed to confirm this assumption

To explain the differential extinction of evergreen taxa, Wolfe and Upchurch[11] suggest a 1–2 month low (near 0 °C) temperature change at or near the boundary The magnitude and duration of such an excursion is clearly constrained by the high survival rate of large aquatic ectotherms[11] But it seems possible that seeds of evergreen taxa survived in the seed bank and re-established when conditions became less hostile

Despite possible problems with such details, it seems clear that the vegetation did change across the K–T boundary in the Aquillapollenites province[9–11] Angiosperm-dominated forests were destroyed and a fern-dominated, coal-forming mire vegetation became established immediately post-boundary at the same time as marine biotic changes Turnover in angiosperm floras varied according to taxon and geographical area, but included both major extinctions and persistence more or less unchanged across the boundary Post-boundary vegetation was therefore different in many ways from that pre-boundary In some areas conifers increased in abundance and selection for deciduousness had a profound effect on Northern Hemisphere but not Southern Hemisphere vegetation[11]

If volcanism in the Indian Deccan Traps did cause the extinctions, as has recently been suggested[19], it is indeed surprising that the Southern Hemisphere provinces show no evidence of the ecological trauma of the Aquillapollenites province Detailed examination of K–T boundary sections from these provinces is clearly needed The last appearance of the dinosaurs may well have preceded these vegetational changes[8], but of the many possible reasons for the extinction of the dinosaurs, those involving a short cold period or enforced changes in herbivore diet bear reinvestigation □

Dating and correlating the French Mousterian

SIR—We note the thermoluminescence dates from Le Moustier[1] with interest and consider them to be valid and informative in the context of that site However, it is regrettable that in his News and Views piece Paul Mellars[2] has used the publication of these dates as an opportunity to reinterpret the chronostratigraphy of Combe Grenal and, by inference, the early Upper Pleistocene sequence of south-west France

Mellars claims that various lines of chronostratigraphic evidence from "key sites" such as Le Moustier and Combe Grenal now converge to suggest that the Mousterian archaeological sequences are successive rather than parallel Unfortunately, this claim is based on the contentious assumption that data from certain so-called "key" sequences can be simply used to interpret other sites, it omits relevant evidence and it balances perilously on the unjustified correlation of the oxygen isotope record from deep sea core V19–30 with arboreal pollen from Combe Grenal The correlations suggested by Mellars fail to take into account a conventional radiocarbon date and thermoluminescence dates for Combe Grenal[3] and ignore significant stratigraphic non-sequences between layers 55–56 and 35–36 at Combe Grenal and H1 and G4 at Le Moustier The proposed correlation between the sites would imply an average error of 50 per cent in the available thermoluminescence dates Although it is clear that the chronostratigraphic interpretation of the Combe Grenal data is not straightforward[3], an error of this magnitude seems most unlikely (S G E Bowman, personal communication) Indeed, the dates tend to support the alternative hypothesis of considerable overlap between the Le Moustier and Combe Grenal sequences as suggested by Bordes[4] and Laville[5,6]

As an alternative to the thermoluminescence dates, Mellars compares arboreal pollen data from Combe Grenal with the oxygen isotope sequence This correlation is problematic in the absence of independent dating to indicate the chronological position and duration of the pollen sequence Without such dating the comparison of curves that represent ice volume and percentage of arboreal pollen rather than actual temperature is speculative, especially as the latter may vary due to local conditions and taphonomic factors as well as climatic change[7,8]

Mellars uses the correlations in his two figures to support his particular view[9] of the succession of archaeological industries from Ferrassie to Quina and then Mousterian of Acheulian Tradition This view would seem to be supported by his positioning of the La Ferrassie hominid from Peyrony's layer D[10,11] at 60,000–75,000 BP This is surprising because it requires a hiatus in the order of 30,000–40,000 years between layers D and E, assuming the generally accepted dating of 30,000–35,000 BP for the Lower Perigordian archaeological assemblage in layer E Further, it does not allow for the possibility that the burials were inserted into layer D and could postdate both the deposits and, in Mellars view, the Ferrassie assemblage Elsewhere[11] the burials have been said to be late Mousterian, dating from Wurm II at around 37,000 BP On the evidence available it would seem unwise to try to arrange the fossil hominid record in line with the model given by Mellars

Overall, the viewpoint presented seems premature and needs to be considered further in the context of a detailed review of the chronostratigraphic and archaeological evidence Otherwise, to paraphrase Bordes[12] on the subject, we remain at risk of setting Charlemagne on a motorcycle

MELLARS REPLIES—First, I was well aware of the small series of thermoluminescence dates (6 against the 34 for Le Moustier) produced by the British Museum laboratory for the Combe Grenal sequence[1], but these have little if any direct bearing on the central issues The laboratory itself has already expressed serious reservations over the interpretation of several of these dates[1] and drawn attention to the obvious conflict between the two dates of 105,000 and 113,000 years obtained for the basal levels of the sequence and the totality of the geological, palaeobotanical, faunal and archaeological evidence which points to a *minimum* age for these deposits in the region of 130,000–140,000 BP (= ocean core stage 6, or 'Rissian' in the French terminology)[1–3] Dating of a parallel series of samples by the same laboratory from the nearby site of Pech de l'Azé IV has been dismissed by the laboratory as "too young to be acceptable"[4] For this reason, exact interpretation of the Combe Grenal sequence on the basis of the thermoluminescence dates alone would clearly be hazardous

What is significant is that 5 of the 6 thermoluminescence dates for the Combe Grenal sequence are substantially earlier than any of the 34 dates for the Le Moustier succession — which is fully consistent with the general conclusion that the greater part of the geological and archaeological sequence at Combe Grenal is entirely earlier than that at Le Moustier Note that dating of a sample from the upper (but not final) Mousterian levels at Pech de l'Azé IV yielded a date of 19,600 ± 1,600 BP, which is approximately half of the known age of these levels, and demonstrably in error by a factor of at least ten standard deviations on the measured sample age[4]

Second, I am not quite sure I understand the objections to the proposed correlation between the Combe Grenal sequence and the oxygen isotope record in ocean cores, which is based not on my own interpretations but on the correlations already adopted by Laville and others for the major part of the Combe Grenal succession[5,6] The interpretation of the ocean core sequence as a record of climatic fluctuations depends not only on the record of oxygen isotope ratios but also on studies of faunal assemblages in ocean core sediments (as a reflection of sea-surface temperatures)[7] and on the close correlations now established with palaeobotanical records from terrestrial and offshore sites, particularly the long and well-dated pollen sequence from Grande Pile in north-eastern France[8,9] Similarly, the interpretation of the climatic sequence at Combe Grenal depends not only on changing arboreal pollen ratios (though these are the easiest to illustrate in simple graphical form) but on the parallel and mutually consistent records of geology, sedimentology and faunal assemblages[2,3,10] The remarkable similarity in all these independent records of climatic change can hardly be dismissed by a passing reference to "local and taphonomic factors" and provides unambiguous support for the climatological/chronological correlations proposed by myself, Laville[5], Dennell[6] and others for the Combe Grenal succession

Third, limited depositional hiatuses should perhaps have been indicated in figures 1 and 2 of my article between layers G and H at Le Moustier and layers 35 and 36 at Combe Grenal — but these episodes have no bearing on the specific correlations proposed between the two sites

Fourth, I fully accept the implications of a major hiatus between the Mousterian and Upper Palaeolithic levels at La Ferrassie Similar depositional/erosional hiatuses are well documented at several other cave and rock-shelter sites in south-west France, for example between the

Mousterian and Solutrian levels at Le Placard, and between the Mousterian and Aurignacian levels at Abri Caminade[2,11] Positive indications of this hiatus can be seen in recently published sections of the site[14] The suggestion that the Neanderthal burials at La Ferrassie represent later instrusions into the Mousterian levels is intriguing, but difficult to evaluate, 80 years after the original excavations

Finally, Cook and Ashton make no allowance for the wealth of purely archaeological evidence bearing on the wider problems of Mousterian chronology and intercorrelations between sites Any attempt to support the stratigraphic correlations of Laville[2,12] would need to explain why at least 12 sites in south-west France show a consistent sequence of Mousterian of Acheulian tradition above Quina/Ferrassie industries, why Mousterian of Acheulian tradition industries invariably occur at the top of Mousterian sequences in cave and rock shelter sites, and why Mousterian of Acheulian tradition industries are entirely lacking from all except the uppermost 4 of the 55 levels of Mousterian occupation at Combe Grenal[13] No explanation has so far been offered as to how these observations can be reconciled with the hypothesis of a close synchronism between the archaeological sequences at Le Moustier and Combe Grenal

What can AIDS virus codon usage tell us?

SIR—Macromolecular sequence comparison is extraordinarily useful in elucidating evolutionary relationships, largely because divergence rates are approximately constant, and the chance of convergence is very small The close evolutionary relationship of the human immunodeficiency virus (HIV) and visna virus has been well characterized by this approach[1,2] Grantham, largely responsible for demonstrating that patterns of codon choice are species are species specific[3], and Perrin now suggest that comparison of such patterns in HIV and visna may provide a useful approximate evolutionary distance[4]

Decomposition of a DNA sequence into a codon usage table loses a great deal of information — comparisons of the intact sequences of homologous genes and proteins must be more informative than comparisons of codon choice In fact, the distance measure used by Grantham and Perrin (how many of 18 amino acids have the same most-preferred codon in two codon usage tables) can yield some strange results For example, among the viruses in Table 1, it is thought that Moloney murine leukaemia virus (MMLV, another retrovirus) is the most closely related to HIV, and yet HIV codon usage is most similar to that in the influenza virus, and even cauliflower mosaic virus (CAMV) is more similar to HIV than is MMLV Also, a compilation of 66 mouse genes[5] yields the same preferred codons as the human (total) for each of the 18 amino acids, and yet differs from 60 rat genes[5] for two amino acids Thus, unlike divergence in protein and DNA sequences, differentiation at the level of codon usage is clearly not linear with time It is also highly susceptible to convergence

Table 1 Similarities of codon choice between organisms

	(*N*)	HIV	E LO	E HI	Baci	Y LO	Y HI	H AT	H CG
Human (total)	(135)	2	8	8	1	2	7	3	14
Human G+C rich	(8)	0	8	10	1	0	7	1	
Human A+T rich	(8)	12	8	5	13	14	7		
Yeast HI	(38)	5	2	11	6	11			
Yeast LO	(66)	11	6	6	13				
Bacillus	(21)	11	9	7					
E coli HI	(42)	2	8				5	(3)	MMLV
E coli LO	(58)	6				10	1	(28)	AD2
					3	6	12	(6)	SV40
				11	1	5	13	(8)	Flu
			10	7	5	8	8	(2)	CAMV
			Flu	SV40	AD2	MMLV	HIV		

Values are the number of amino acids (out of 18) where the two data sets show the same preferred codon *N* is the number of genes in each data set Yeast, *Saccharomyces cerevisiae*, *Bacillus*, *B subtilis* HI and LO (for *E coli* and yeast) indicate groups of genes identified as having high and low codon bias Human GC-rich α-actin, apolipoprotein A1, β-chorionic gonadotropin, α-globin, ζ-globin, metallothionein II, insulin, α-tubulin Human AT-rich albumin, α-amylase (pancreatic and salivary), factor IX, γ-fibrinogen, γ-interferon, HPRT, parathyroid hormone Viruses HIV, 5 genes (*gag, pol, sor, env, P27*) of ARV-2, Moloney murine leukaemia virus, Flu, influenza virus isolate B/Lee/40, SV40, simian polyoma, CAMV, cauliflower mosaic virus, AD2, adenovirus 2 All codon usage data was taken from ref 5, except yeast[6], *Bacillus*[10], *E coli*[7] and HIV (calculated from GenBank)

Furthermore, it is clear that there is considerable heterogeneity in codon choice among genes within species In *Escherichia coli* and yeast (the two best studied organisms) groups of genes with high and low codon bias can be identified[3,6,7] that differ somewhat in their preferred codons (Table 1) In mammals there are also large differences among genes in the direction of codon preference[8] These differences seem to be related to local genomic G+C content[8], and can yield very different sets of preferred codons

Thus, when Grantham and Perrin use their comparison to estimate the extent to which viruses imitate the codon preference of their hosts[4], and point out that codon usage in HIV genes is different to that in a compilation of all human (excluding immune system) genes, this is somewhat misleading In fact, HIV genes show considerable similarity in codon choice to a group of human genes with low G+C content Comparing species totals, HIV codon usage shows more similarity to that in *Bacillus subtilis* and yeast, than to that in the compilation of human genes

On the positive side, it is possible that the differences among mammalian genes in pattern of codon usage may partly reflect the diverse tissues in which those genes are expressed One investigation of this possibility[9] gave negative results, but examined very few genes It may be that codon usage in HIV genes reflects adaption to expression in particular tissues, in which case the report[4] that there is some similarity in this respect between HIV genes and T-cell receptor genes would be rather interesting

Colonization of space: destiny or folly?

Von R Eshleman

The US National Commission on Space has grandiose plans for the colonization of the Solar System. Has the view that unmanned missions may bring much greater benefit to mankind been passed over?

THE presidentially-appointed National Commission on Space has recently released an expansive agenda for the US space programme in the first quarter of the twenty-first century (*Pioneering the Space Frontier*, Bantam Books, Inc., New York, 1986). With space enterprise, exploration and science as components, the overall rationale behind this vision of the future is founded on an assumption that the human species is destined, within the foreseeable future, to colonize space.

But this assumption is not critically examined. It is offered as an act of faith, as though it were rendered self-evident by references to Columbus and 'The New World', the settlement of the American West, and the pioneering spirit that has served us so well in the past.

These are indeed powerful images, but do they necessarily make space colonization a human imperative? I do not question whether it could be done so much as to wonder why it is assumed that it should be done. I would worry about unresolved difficulties, but my main concern is the danger of precluding alternative possibilities of greater promise.

The commission envisages that by the year 2000, the United States would have an Earth Spaceport, with crew, for storage, fueling, repair, supply, maintenance, and launch of transfer and orbital manoeuvering vehicles for access to more distant locales. By the year 2025 there would be three additional spaceports with human crews, including one near Mars, staffed spaceships continually cycling between the orbits of Mars and Earth, manufacturing at a permanent human base on the Moon, astronaut outposts on Phobos and Deimos, the small moons of Mars, and an exploratory base on the surface of Mars which would become a fully-staffed permanent base within a few years. It is stated that this 'Highway to Space' and 'Bridge Between Worlds' would provide the infrastructure for space applications and science, while serving as a focal point for international cooperation and advances in technology. And it would initiate the colonization of the Solar System.

Will this proposal for pioneering the space frontier prove to be prophetic or visionary? It is intended to help influence future events so as to become the former, but current events and their origins suggest that it could well be the latter. It is my opinion that the commission's proposals, if initiated, would lead to a continuation of the fundamental failure of the US space programme to use national resources most effectively for progress at the frontier of space. The crux of the problem, I submit, is an inappropriate mix of the relative influences of our space ends and means and sometimes dreams.

In the report, for example, it is the dream of colonization that determines the proposed infrastructure of spaceports, cycling spaceships and lunar and martian bases. But these are simply means, the ends are primarily the exploration and commercial and scientific use of the space environment. Is there not a danger that the means will become ends in themselves? The question is not even asked the other way around. If all manner of space manufacturing, Earth remote sensing, space communications, planetary exploration, and space science laboratories and observatories are indeed our main ends, by what means may they best be realized? This inevitably brings up the decades-old debate concerning the relative importance and roles of manned and unmanned space endeavours. In the commission's view, the debate is finished. Human crews, settlers, and vacationers belong wherever they conceivably can go. In this scenario, the next frontier will be conquered as before, with a wave of human pioneers.

Ultimate frontier

But mankind could expand into the ultimate frontier of space in another way. Never before have we had the ability to observe, explore, utilize, examine, monitor, manipulate, prospect, mine and manufacture, or in short pioneer and operate at a new physical frontier, without the necessity of a physical human presence at that frontier. In a way, humanity as a whole could experience its continuous expansion into thousands of locales at the frontier of space, with a multitude of its doers (like the hand of Viking 1 as it clutched a sample from an ancient plain of Mars) and sensors (like the eyes of Jason Jr as it descended the grand staircase of the Titanic or the magnetometers of Voyager 2 as they charted the bizarre field of Uranus) on the ends of thousands to billions of kilometre-long radio nerve fibres and commandable sinews. Remote human monitoring and control of space manufacturing and delicate experimentation could also be accomplished.

The means to secure these ends would be low-cost unmanned launch and transfer vehicles and new levels of capabilities in robotics, communications and control, adaptive and expert systems, and many related technologies. Our collective space dreams could encompass the endless possibilities for international cooperation in obtaining new knowledge, products and resources from space in this way, and the endless potential of applying them to better the human condition on Earth. Such dreams include an automation revolution to rival the industrial revolution in significance, and new levels of understanding of climatic effects like carbon-dioxide warming, nuclear winter and acid rain from remotely controlled examinations of related phenomena on other worlds. Concerns about national prestige and demonstrations of technological prowess, as with Apollo, or dreams about solving international tensions by a joint symbolic venture in space, such as a human mission to Mars, do not appear to me to be useful guides for progress.

The current hiatus in American access to space due to the Challenger disaster should be used to re-appraise our goals and the methods for their realization. It is clear that the present problems would have surfaced in some way, even if the tragic accident had not occurred. Although many observers have cheered the decision by President Reagan to replace Challenger, some seem to have missed the significance of the accompanying announcements that the United States will phase out commercial and foreign payloads for the shuttle fleet, and will encourage the commercialization of launch services after the 15-year delay that was enforced by nationally-subsidized competition. This stands as a tacit admission that we have failed to realize the fundamental rationale for the space shuttle programme, namely, that of providing low-cost access to space for all US and many foreign users.

The shuttle experience stands as one example of the kinds of things that could go wrong if we try to bypass incremental, well-funded, long-term progress based on carefully defined goals and feasible, cost-effective means tailored to those ends. I submit that space colonization is a dream whose time has not yet come, and that the benefits of the space frontier beckon us to realize them in the most direct and effective ways possible. □

The quark plasma

H. Satz

Fakultat fur Physik, Universitat Bielefeld, Postfach 8640, D-4800 Bielefeld 1, FRG
and Physics Department, Brookhaven National Laboratory, Upton, Long Island, New York 11973, USA

Because nucleons are bound states of quarks, nuclear matter should at sufficiently high density become a quark plasma. Assuming quantum chromodynamics as the basic theory of nuclear forces, it is possible to derive strong-interaction thermodynamics and study the nature of this transition. Predictions of thermodynamic variables are obtained by computer simulation; they provide the first theoretical information on the phase structure of strongly interacting matter. The experimental search for the quark plasma is beginning this year at Brookhaven and at CERN. Energetic nuclear collisions could produce sufficiently dense and long-lived strongly interacting systems to allow a first look at the predicted new state of matter.

IN the past two decades our picture of an elementary particle has changed significantly Today we consider protons, neutrons and all the other 'elementary' particles in the realm of nuclear forces as composite as bound states of quarks Elementary particles are no longer the smallest units of matter, they, in turn, consist of quarks The binding force between quarks is quite different, however, from the forces usually encountered in physics: at short distances it becomes so weak that the quarks appear to be free, but with increasing distance of separation, it grows without limit Thus it is not possible to split an elementary particle into its quark constituents—this would require an infinitely large force Elementary particles remain the smallest units of matter that can exist by themselves, individually, quarks can only exist together with other quarks or antiquarks

This modified view of the elementary particle concept has in turn had a profound effect on our picture of nuclear matter at high density If nucleons (protons and neutrons) were elementary hard spheres, then a densely packed system of such objects would be the limiting state of matter (see Fig 1) For composite nucleons, however, interpenetration will occur if the density is increased enough, and eventually each quark will find very many others in its immediate neighbourhood Because it has no way to remember which of these were its partners in the low-density nucleonic state, the concept of a nucleon and of nuclear matter has become meaningless here Thus it is expected that at a high enough density a new state of matter will appear the quark plasma—a system whose basic constituents are unbound quarks

Before considering in more detail how quark binding can be dissolved in dense matter, let us get some idea of the densities involved Dense atomic solids contain about 10^{23} nucleons cm^{-3} nuclear matter, as it exists in the interior of neutron stars, has about 10^{38} nucleons cm^{-3}, and is thus 10^{15} times denser than matter in the world around us What is the effect of further compression in this regime of extreme density?

I have already noted that the strength of the binding force between quarks increases indefinitely with their separation, making the 'ionization' of a nucleon into its quark constituents impossible the quarks are 'confined' Why then should they become deconfined in sufficiently dense matter? The answer to this question is found in charge screening, which already occurs in atomic solids The force between the charged partners of a bound state is considerably modified, if this bound state is placed in an environment of many other such objects The Coulomb potential between two electric charges e, separated by a distance r, has in the vacuum the form e^2/r, in the presence of many other charges it becomes subject to Debye screening, $e^2/r \rightarrow (e^2/r)\exp(-r/r_D)$, where the screening radius r_D is inversely proportional to the overall charge density of the system the more other charges present in the environment, the shorter the range of the force between two given charges If in atomic matter the Debye radius r_D becomes less than the atomic radius r_A, then the binding force between electron and nucleus is effectively screened, and the electron becomes 'free' For atomic systems, an increase in density thus results in an insulator-conductor transition[1,2] the binding between charges is dissolved in the presence of enough other charges

Screening, in contrast to ionization, is thus a short-range mechanism to dissolve bound states, and for this reason we expect it to apply also to quark binding I shall return shortly to the theoretical basis of the force between quarks, note here only that the interaction is again based on a charge, the 'colour' charge, which in strong-interaction physics plays the role of the electromagnetic charge in atomic physics Nucleons are colour-neutral bound states of colour-charged quarks, and hence nuclear matter corresponds to a colour insulator With increasing density, colour screening should set in and lead to the transition from colour insulator to colour conductor to the quark plasma The predicted new state of matter thus is a macroscopic system which is conductive to the basic charge of the strong interaction

The theoretical analysis of strongly interacting matter is based on the fundamental theory for the interaction of quarks, quantum chromodynamics I shall survey the present state of this analysis in the next section The experimental investigation of these phenomena is the main aim of forthcoming studies of

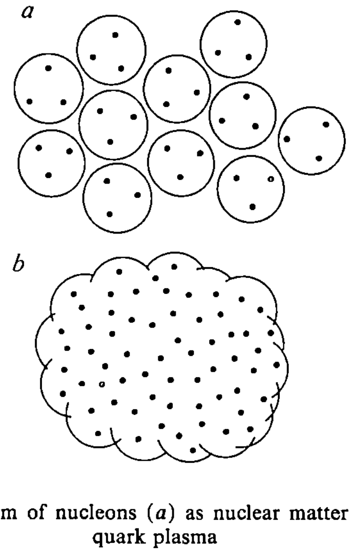

Fig 1 A system of nucleons (*a*) as nuclear matter and (*b*) as quark plasma

ultrarelativistic collisions of heavy nuclei, this will be taken up in the section after next

Statistical quantum chromodynamics

Quantum chromodynamics (QCD) describes the interaction of quarks in much the same way as quantum electrodynamics (QED) does for electrons Spinorial matter fields ψ—here quarks, electrons in QED—interact through massless vector gauge fields A, here gluons take the place of photons Just as in QED, the interaction in QCD is determined by an intrinsic charge, the 'colour', each quark can be in one of three different colour charge states In contrast to QED, however, the gauge fields here also carry a charge each gluon can be in one of eight colour states As a result, the gluons, as well as the quarks, interact with each other, and it is in fact this gauge-field interaction that is the crucial feature of QCD Gluonic lines of force between two quarks now attract each other, and this turns the three-dimensional Laplace equation, with the Coulomb solution $V(r) \sim 1/r$, into a one-dimensional form, with $V(r) \sim |r|$ as 'confining' solution

The Lagrangian density of QCD has the form[3-5]

$$\mathscr{L} = -\tfrac{1}{4} F^a_{\mu\nu} F^{\mu\nu}_a - \sum_f \bar{\psi}^a_f (\imath - g)_{\alpha\beta} \psi^\beta_f \qquad (1)$$

with

$$F^a_{\mu\nu} = (\partial_\mu A^a_\nu - \partial_\nu A^a_\mu - g f^a_{bc} A^b_\mu A^c_\nu) \qquad (2)$$

Here $a, b, c = 1, \quad , 8$, and $\alpha, \beta = 1, 2, 3$ denote the gluon and quark colour charges, respectively, they are based on SU(3) as the colour gauge group, whose structure constants are f^a_{bc} The explicit summation in equation (1) runs over the possible different species ('flavours') f of quarks, I restrict myself here to the (practically massless) u and d quarks, which suffice to construct all non-strange nucleons and mesons

Note again that it is the last term in equation (2), and hence the non-abelian nature of the gauge group[6], which constitutes the crucial feature of the theory, for $f^a_{bc} = 0$, equations (1) and (2) have the same structure as QED

The Lagrangian (1)/(2) contains a single, dimensionless coupling g As a result, QCD cannot predict any dimensional observable, but only the dimensionless ratios of observables In many ways, such a description comes close to an ideal physical theory it is closed in itself, and contains no outside parameters As shown below, QCD thus predicts for instance the transition temperature from nuclear matter to quark plasma in units of the nucleon mass, and this mass is itself calculated within the theory as the lowest bound-state energy of three massless quarks

Given the Lagrangian density (1)/(2), we have in principle all the dynamical input necessary for strong interaction thermodynamics From $\mathscr{L}$, we must determine the Hamiltonian H, and then construct in the usual way the partition function

$$Z(T, V) = \mathrm{Tr}(\exp(-H/T)\} \qquad (3)$$

for a thermodynamic system at temperature T and within a spatial volume V, the trace in equation (3) runs over all microscopic physical states From Z, we obtain by differentiation the desired thermodynamic observables, getting for instance $\varepsilon = (T^2/V)(\partial \ln Z/\partial T)_V$ for the energy density, and $P = (\partial \ln Z/\partial V)_T$ for the pressure But how is it possible to carry out the actual evaluation of Z? The perturbative approach familiar from QED could be applied here as well for the regime in which the interactions are weak—that is, at very high density But the central theme of statistical QCD, the transition from the strongly coupled nuclear matter to the weakly coupled plasma, is by nature non-perturbative and cannot be addressed in such a fashion

The only approach known at present that permits us to study strongly interacting matter at all densities is the lattice formulation introduced by Wilson[7] Replacing the space-time continuum, on which the fields ψ and A are defined, with a discrete and finite set of lattice points, one obtains a form of the partition function that is divergence-free and, moreover, structurally very similar to that of spin systems in statistical mechanics It is therefore possible to use the computer simulation techniques developed for such spin systems in the evaluation of lattice QCD[8] Renormalization group theory, which studies the scale-dependence of statistical systems, then permits us to recover the continuum limit (vanishing lattice spacing) of the results thus obtained In the past few years this method of evaluation has been applied extensively and with considerable success in the study of the phase structure of strongly interacting matter (for a recent survey, see ref 9)

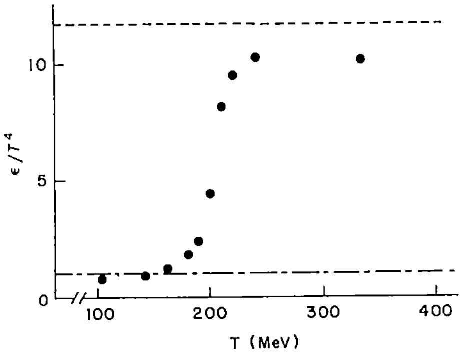

Fig. 2 The energy density of strongly interacting matter as a function of the temperature compared with the energy density of the ideal quark-gluon plasma (---) and of the ideal pion gas (- - -) (From ref 12)

After taking a brief look at the computer simulation of statistical systems[10], I shall here go on directly to the results obtained so far

The analytical mathematics available today has been developed to a large extent for isolated systems, even very simple many-body systems with interaction cannot generally be solved, once the interaction really connects the whole system and is not perturbatively reducible to small parts of it As an example, recall that the three-dimensional Ising model is not analytically solved In recent years, with the advent of large-scale computers, it has become possible to simulate such systems the given system is reproduced on the computer in a specific microscopic configuration In reproducing all possible configurations, it would then be possible to evaluate $Z(T, V)$ exactly for systems of finite size Because the three-dimensional Ising model—N^3 spins pointing either up or down—already leads to 2^{N^3} configurations, it is evident that for meaningful systems such a procedure is not feasible, even on the largest computers Therefore, in statistical physics Monte Carlo methods have been developed to generate 'typical' configurations[11], and, averaging over a sufficiently large number of these for the simulated system, it is possible to 'measure' the thermodynamic quantities of interest

The density of strongly interacting matter can be increased in two distinct ways by compression, or by heating, which owing to the relativistic energy range involved leads to particle production and hence a higher density So far most of the results of statistical QCD deal with the latter of these two cases, with 'hot mesonic matter' of vanishing baryon number density The other extreme, the compression of 'cold nuclear matter', is now the subject of much study, the computer simulation of this system is technically more difficult

Beginning with matter of vanishing baryon number density, the energy density of a non-interacting gas of massless quarks and gluons is

$$\varepsilon_P = (37\pi^2/30) T^4 \simeq 12 T^4 \qquad (4)$$

Just as in the Stefan-Boltzmann form for the photon gas, the numerical factor in equation (4) is determined by the number of degrees of freedom of the constituents involved their spins, colours and flavours Similarly, a gas of non-interacting π mesons becomes, if we neglect the meson mass, $\varepsilon_\pi = (3\pi^2/30)T^4 \simeq T^4$, taking into account the three possible charge states of the π In the low-temperature region, where quarks are confined, we might expect values of ε in this range, whereas at high enough temperatures the plasma form (4) should become correct The energy density obtained by computer simulation of statistical QCD[12] is shown in Fig 2, there is a very rapid transition from the mesonic regime to the plasma The transition temperature—converted to physical units through comparison with the mass of the nucleon or the ρ meson—is around 200 MeV, which in turn means that an energy density of at least 2 5 GeV fm^{-3} is necessary to create a quark-gluon plasma

Before we turn to nuclear matter, a further aspect related to the deconfinement of quarks should be noted An electron in a conductor has an 'effective' mass different from that in a vacuum or in an atom This mass shift is the consequence of collective effects of all the positive ions and other electrons present Similarly, we can consider an 'effective' quark mass, which in the confined phase is around 300 MeV (corresponding to the three constituent quarks of a nucleon), in the weakly interacting plasma it vanishes This shift in the effective quark mass need not exactly coincide with deconfinement In principle it may occur later, which would lead us to a three-phase structure for strongly interacting matter hadronic matter, consisting of mesons and nucleons, a constituent quark plasma, consisting of massive but deconfined quarks, and finally the quark-gluon plasma of massless quarks and gluons For systems of vanishing baryon number density, however, statistical QCD has shown that the two phenomena indeed do occur at the same point[12,13]

Systems of non-vanishing baryon number density—'nuclear' or 'baryonic' matter—are now a subject of considerable attention The partition function depends in this case on a further variable the baryonic chemical potential μ, which through $n_B = (T/V)(\partial \ln Z(T, V, \mu)/\partial\mu)$ determines the overall baryon number density of the system (the number of baryons minus that of antibaryons, per unit volume) So far, numerical studies have been made only for rather small values of μ[14,15] The resulting phase diagram is shown in Fig 3, up to this point, deconfinement and quark mass shift still coincide Whether that will remain true even at very low temperatures, or whether the mentioned additional phase, the constituent quark plasma, makes its appearance there, remains to be seen

Nuclear collisions at high energies

The thermodynamics of strongly interacting matter is of importance to cosmology Very soon after the Big Bang, the Universe must have been a hot, dense quark-gluon plasma, its rapid expansion presumably reduced the density such that after about 10^{-3} s the transition to the hadronic Universe occurred Only from that point on was there a physical vacuum

In recent years the possibility of recreating this cosmological process in the laboratory has come within reach[16] The collision of two heavy nuclei at high enough energies should produce a 'little bang', providing a bubble of strongly interacting matter sufficiently large and of sufficiently long lifetime to allow the application of statistical QCD, that is, it should form the quark plasma, and make possible the study of the transition to hadronic matter What is the physical basis for this?

When two nucleons collide at high energy, as for example in one of the large proton accelerators at CERN (Geneva) or Fermilab (Illinois), they almost always just pass through each other In the process the nucleons are excited, but in addition they leave a 'condensation trail' of deposited energy in the region of space they passed through (see Fig 4) This energy is rapidly transformed into hadrons, the secondary particles usually produced in such collisions From the analysis of proton-proton collision data, it is known that the deposition of energy at high enough energies is about 1/3 GeV fm^{-3} It does not increase much more with a further increase in collision energy, which only makes the condensation trail longer

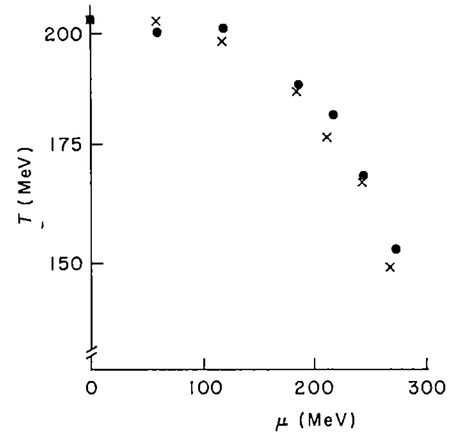

Fig 3 The dependence of the deconfinement temperature (×) and the chiral-symmetry restoration temperature (●) on the baryonic chemical potential μ, increasing μ means increasing the baryon number density (From ref 15)

If instead of the nucleons, two heavy nuclei collide (for simplicity, both with mass number A), a multiple superposition of the phenomenon just described is obtained, so that a given region of the condensation trail now receives a much larger deposition of energy[17] Simple geometrical arguments lead to an energy density of at least $\varepsilon \sim A^{1/3}$ GeV fm^{-3}, this means that an energetic collision of two ^{238}U nuclei provides an average deposition of about 6 GeV fm^{-3} As seen in the previous section, this is well above what is needed for plasma formation

Processes of this type can also be simulated on large computers, using simple phenomenological interaction models as input, One such stimulation (done by D Strottman (Los Alamos), based on a model he developed with A S Goldhaber (Stony Brook)) is shown in Fig 5, we see clearly the formation of the condensation trail after the nucleons have penetrated each other The process shown here is the collision of a ^{16}O nucleus with a^{238}U target, at an incident energy of 100 GeV per nucleon Such reactions will be the first to be studied in forthcoming experiments at CERN (Geneva), I shall return to the experimental situation shortly

Nuclear collisions should thus produce bubbles of rather high energy density, and of a volume $V_A \sim A$ fm^3, although not really macroscopic, V_A is, for large A at least, much bigger than the typical hadron volume of about 1 or 2 fm^3 It is therefore hoped that such a bubble represents a system to which the equation of state obtained in statistical QCD may be applied, if the energy

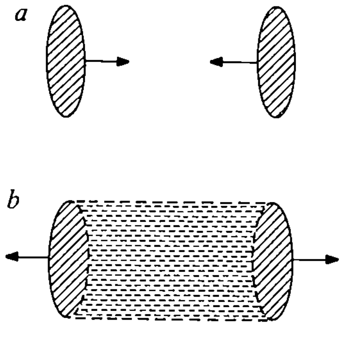

Fig 4 High-energy collision of two nucleons (a) just before, (b) just after the collision

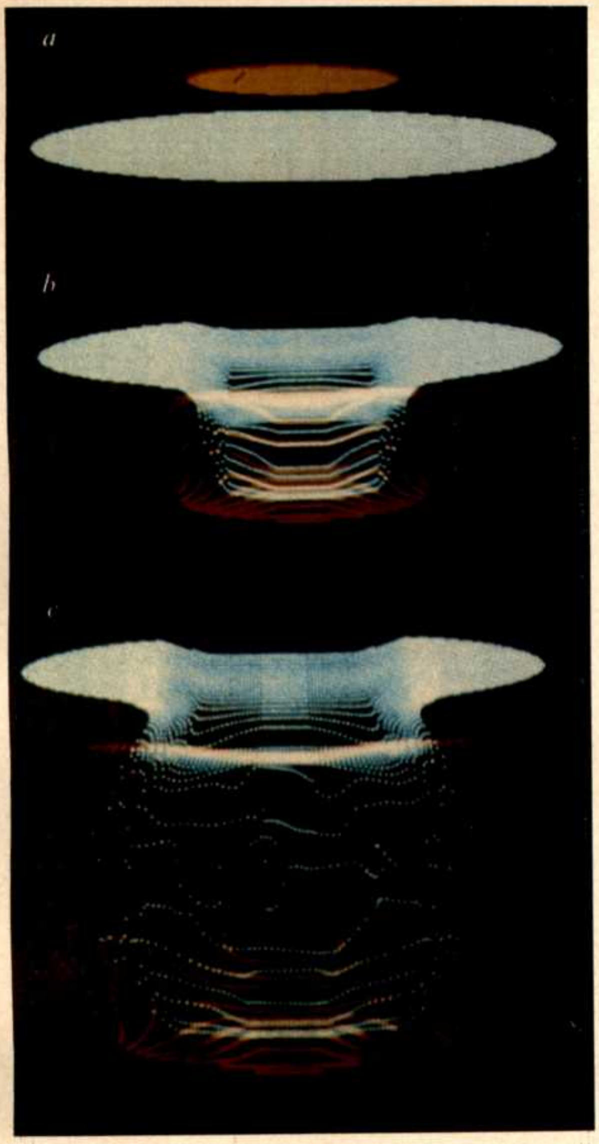

Fig. 5 Successive stages of a high-energy nuclear collision: ^{16}O at 100 GeV per nucleon on ^{238}U; (*a*) at approximately 10^{-24} s before the collision, (*b*) at 2×10^{-23} s and (*c*) at 10^{-22} s after the collision. (From the computer simulation by D. Strottman.)

deposit is high enough, the initial temperature will be high, and the bubble will contain quark matter.

Each plasma bubble will now expand quite rapidly and in doing so cool down to the deconfinement transition temperature. Hadrons—predominently mesons—will form, and after still further expansion, at the energy density of about 1/3 GeV fm^{-3}, they will cease to interact and form the secondary particles produced in the collision. The plasma expansion has been a subject of much recent work[18]; it is usual to apply the hydrodynamic flow equations, using an equation of state of strongly interacting matter (ideally that obtained from statistical QCD) as input.

Given this model for plasma formation and transition in nuclear collisions, how can it be tested experimentally? What are the signatures for the creation of a new state of matter in such interactions? What has emerged so far is a number of different indications, which, if all observed together, would make plasma formation the most likely explanation.

At the time when any measurement is made, the 'little bang'—provided it occurred—is over. Hence one thing to look for is a signal from the initial plasma phase that is not affected by the subsequent transition. If quarks in the plasma, by collision or annihilation, emit photons, then these, because of the much weaker electromagnetic interaction, will generally escape from the system without further interactions. The spectra of photons, real or virtual (as e^+e^- pairs), should thus tell us something about the early stage of the produced system.

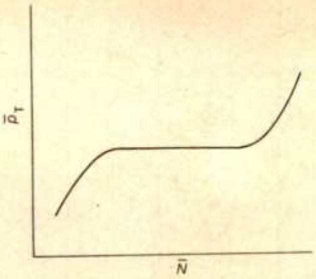

Fig. 6 Schematic dependence of the average transverse momentum $\bar{p}_T$ of hadronic secondary particles on the average number $\bar{N}$ of such secondary particles, as expected for energetic nuclear collisions leading to a first-order deconfinement-confinement transition. (From ref. 19.)

Because the number of produced secondary hadrons is directly related to the initial energy density, the multiplicity in a given collision may serve as an indicator for ε. In the condensation trail we find bubbles of various momenta in the longitudinal direction (that is, along the collision axis). Hence the longitudinal momenta of the secondary particles are not directly related to any specific plasma bubble. The average transverse momenta $\bar{p}_T$ can be so related, however, and thus provide a measure of the initial temperature: the higher p_T, the greater the momentum boost due to the plasma expansion must have been, and hence the higher the initial temperature *T*. Thus, using $\bar{p}_T$ as a measure of temperature and the multiplicity $\bar{N}$ in a given momentum range as a measure of energy density, from Fig. 2, the $\bar{N}$ dependence of $\bar{p}_T$ should be as shown in Fig. 6[19]. Indeed, there are first indications for such a behaviour, obtained from the study of nuclear collisions in data from cosmic rays[20].

For a survey of experimentally observable signatures see ref. 21. As this article was being completed, a further and apparently rather clear signal for plasma formation was developed[22]. If deconfinement occurs, then the production of J/Ψ mesons in nuclear collisions must be very strongly suppressed, because within the plasma the charmed quark constituents of the J/Ψ cannot form a bound state, and the large mass of the J/Ψ prevents it from being formed in a later stage. No other mechanism for such a suppression is yet known. It should be emphasized, however, that with the study of dense hadronic systems we enter an unexplored region of physics, and thus surprises are to be expected.

The experimental study of high-energy nuclear collisions is scheduled to start this year. At Brookhaven National Laboratory a beam of ^{32}S ions at 15 GeV per nucleon should become available in October 1986, and three major project groups plan to perform experiments with this beam. At CERN a beam of ^{16}O (perhaps also ^{32}S) ions, of energies up to 200 GeV per nucleon, will be used by five major experimental groups in a three-week run starting in November 1986. In both laboratories there will be additional smaller-scale emulsion experiments. It is certainly hoped that these studies may provide first indications of the quark plasma; nevertheless in both cases the ions are not very heavy, and *A* should be large to obtain as 'macroscopic' a system as possible. At Brookhaven a booster facility is under construction, which will allow the acceleration of ions as dense as gold (^{197}Au); it should go into operation in around 1989. Beyond these projects, which rely on existing accelerators both at BNL and CERN, there are plans for the construction of a machine dedicated to high-density hadron physics at Brookhaven. This relativistic heavy ion collider (RHIC) would provide a colliding nuclear beam facility, with energies of around 100 GeV per nucleon in each beam for even the heaviest ions. A first decision on this proposal is expected soon.

Why do a rapidly growing number of physicists find these prospects so exciting? It appears to be within reach to study the states of matter in strong interacting physics, and in this study to recreate experimentally in the laboratory a crucial stage in the development of the early Universe.

Organization of anterior pattern in the *Drosophila* embryo by the maternal gene *bicoid*

Hans Georg Frohnhöfer & Christiane Nüsslein-Volhard

Max Planck Institut für Entwicklungsbiologie, Spemannstrasse 35, 74 Tübingen, FRG

Embryos derived from bicoid (bcd) *females lack head and thorax. Cytoplasmic transplantation experiments reveal that* bcd^+*-dependent activity is localized at the anterior pole of wild-type embryos. The activity can induce anterior development in mutant embryos at any position along the antero-posterior axis and suppresses posterior development.*

WHEN the young *Drosophila* embryo proceeds through the stages of syncytial blastoderm towards gastrulation, the perivitelline layer of somatic nuclei looks almost homogeneous, with no morphological signs of cellular specification. But when the blastodermal layer is examined with molecular probes, the spatially restricted transcription of segmentation genes reveals that it is already being subdivided into segmental units[1-3]. It has frequently been proposed that maternally encoded functions provide positional information in the egg and control the spatial pattern of zygotic gene expression, which in turn determines the developmental fate of individual cells. In insects, there is evidence for two centres of activity, located at the egg poles, which organize the antero-posterior axis (reviewed in ref. 4). In *Euscelis* transposition of posterior polar plasm within the egg can induce a duplicated posterior end with inversed polarity[4]. An analogous activity was found at the anterior in chironomid midges; manipulation of the anterior pole can cause double abdomen formation (reviewed in ref. 5). The activity appears to be required for anterior and to inhibit posterior development. The anterior activity in *Smittia* is sensitive to RNase and ultraviolet irradiation[5] and are therefore characterized as RNA-containing particles.

Evidence for terminal organizing centres has been obtained in *Drosophila* by experimental removal and/or transplantation of polar cytoplasm[6]. Specific, distinct phenotypes are produced which resemble the phenotypes of several maternal effect mutants. This suggests that the genes involved are important in the establishment of the morphogenetic centres. Five loci are known in which mutations eliminate the posterior pole plasm, including the polar granules. No pole cells are formed and the development of the abdomen is abolished. Strikingly, the posteriormost somatic region of the embryo, the telson, is not affected[7-9]. In *oskar* mutants (osk^-), abdominal segmentation can be restored by transplantation of wild type pole plasm into the prospective abdominal region[9]. Only pole plasm from osk^+ embryos can induce posterior development at the anterior, suggesting that this group of genes is involved in the organization of posterior pattern[6,9].

The anterior structures, head and thorax, are eliminated by maternal effect mutations of the bicaudal group[10-12]. Head and thorax are replaced by a second duplicated abdomen (including telson) of reversed polarity. Bicaudal embryos are produced by mutations in a variety of complementation groups with quite different genetic properties, but in no case with 100% penetrance[12]. Therefore these mutants do not readily define functions specifically required for anterior development. Here we describe the maternal effect gene *bicoid* (*bcd*). Embryos produced by mutant females lack head and thorax and have a second duplicated telson at their anterior end, but usually no abdominal segments of inversed polarity. We show that the function of *bcd* is mediated by a cytoplasmic activity, localized at the anterior, with long range organizing effects on the antero-posterior pattern.

Phenotype of *bicoid*

All eleven *bcd* alleles are strictly maternal. The penetrance is 100%, but the alleles differ in the extent of anterior pattern defects they produce (Fig. 1). Embryos from strong mutant alleles completely lack the head and thorax (Fig. 1*d*); instead they have a second telson at the anterior end. Deletions and fusions of segments are also found in the anterior abdominal region. Occasionally abdominal segments with inversed polarity are duplicated at the anterior, together with the telson. The weakest alleles show pattern defects only in the anterior head

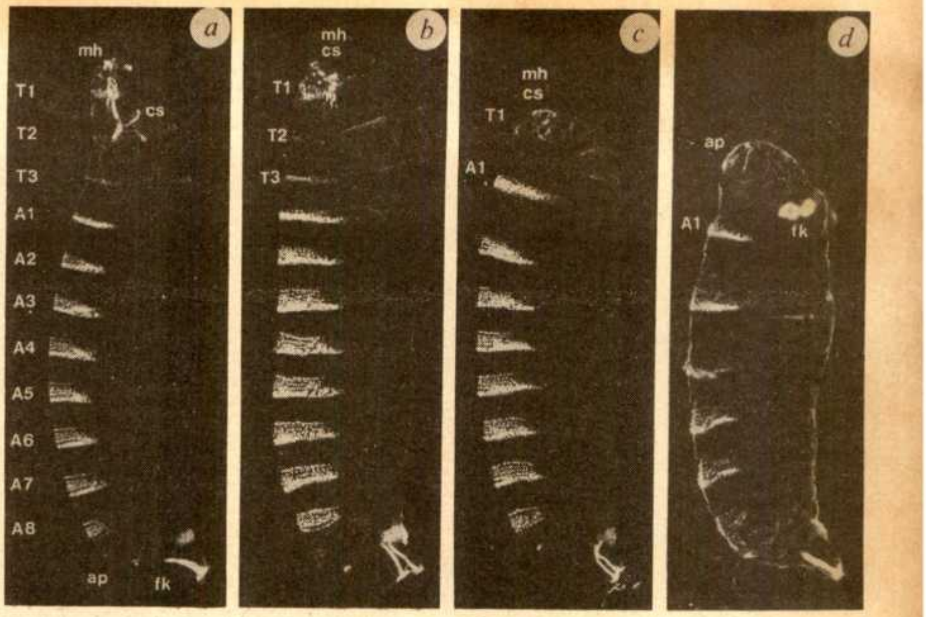

Fig. 1 The phenotype of *bicoid*. Cuticular preparations of embryos of different mutant strength. *a*, Wild type. The weakest *bcd* alleles ($bcd^{2\text{-}13}$, bcd^{E5}, and bcd^{111}) lack only labral derivatives (median tooth, dorsal bridge) and are not shown. *b*, Weak intermediate phenotype (bcd^{E3}/bcd^{E3}, 18°). The entire head is reduced; thoracic and abdominal segmentation is normal. *c*, Strong intermediate phenotype (bcd^{E3}/bcd^{E3}, 25°). The head is further reduced and the thorax is affected. On the ventral side denticle belts T2 and T3 are deleted and T1 is reduced in size. Three dorsal bulges with segmental arrays of dorsal hairs demonstrate that the thoracic region is still composed of all three segments fused together. Intermediate alleles: bcd^{E3} (strongly temperature-sensitive), bcd^{E4} and bcd^{085}. *d*, Strong *bcd* phenotype (bcd^{E1}/bcd^{E1}). Head and thorax are lacking altogether. They are replaced by a complete telson with anal plates, tuft, spiracles and filzkörper, but these are not stretched. The anterior abdomen shows segment defects and fusions. Strong alleles: bcd^{E1}, bcd^{E2}, $bcd^{33\text{-}5}$, $bcd^{23\text{-}16}$, bcd^{GB}. A more detailed description of the individual alleles and their temperature dependence will be given elsewhere. Mutant alleles: *Bicoid* alleles were induced with ethyl-methanesulfonate in a marked chromosome and isolated: (1) in a large scale mutagenesis experiment designed for recessive female sterile mutations on the third chromosome (C.N.-V., G. Jürgens, K. Anderson, R. Lehmann & H.G.F., unpublished, see also refs 9, 24) (bcd^{E1}-bcd^{E5}, bcd^{085}); (2) as alleles which failed to complement bcd^{E3} ($bcd^{2\text{-}13}$, bcd^{111}, $bcd^{33\text{-}5}$, bcd^{GB}) or (3) from individual F_1 females heterozygous for a mutagenized chromosome, on the basis of the dominant haploinsufficient phenotype (anterior shift of the head fold) ($bcd^{23\text{-}16}$, *Df*(3*R*)*LIN*). The *bcd* gene is not complemented by *Df*(3*R*)*Scr*, *Df*(3*R*)*LIN*, or *Df*(3*R*)9*A*99, but covered by *Df*(3*R*)Ns^{R+17} and *Df*(3*R*)4*SCB* which places it in 84A into the same cytogenetic interval which contains *zerknüllt*[25-27].

Methods. Embryos were collected on yeasted agar plates, dechorionated and devitellinized. They were mounted in Hoyers mounting medium, diluted 1:1 with lactic acid and cleared by overnight incubation at 60 °C. Darkfield photographs. A1-A8 = ventral abdominal denticle bands, ap = analplates, cs = cephalopharyngeal skeleton, fk = filzkörper, mh = mouth hook, T1-T3 = thoracic denticle bands. Anterior at the top, ventral at left. For the morphology of the larval cuticle see refs 28, 29.

region. With increasing allelic strength the entire head region (Fig. 1*b*), then the thorax (Fig. 1*c*) are affected. Otherwise there is no clear order in which structures are eliminated. Three anterior regions with different sensitivity for bcd^+ reduction can be distinguished; the preantennal head region, antennal and gnathocephalic head segments, and thorax.

In transheterozygous combinations, *bcd* deficiencies behave like strong alleles. The allelic series thus reflects a continuous decrease of bcd^+ activity (hypomorphic states); the strong alleles approximate the complete loss of bcd^+ function (amorphic condition).

Development

Bicoid embryos develop normally until blastoderm formation. Morphological alterations in mutant embryos start at gastrulation. The cephalic fold, indicating the position of the gnathal anlagen, is a good landmark for changes of organization (Fig. 2). Females carrying a duplication or a deletion for bcd^+ produce embryos with the cephalic fold shifted towards a more posterior or anterior position respectively (Fig. 2*a*–*c*). With further decrease of bcd^+ activity in homozygous alleles, the cephalic fold becomes weaker, and finally disappears (Fig. 2*d*). At intermediate mutant strength a posterior midgut plate is formed at the anterior end, indicating a duplicated telson. This is seen more clearly in strong alleles (Fig. 2*e*). However, no pole cells are formed at the anterior end and no pole plasm is found there in the early stages. The shifted cephalic fold reveals that the *bcd* phenotype is associated with changes in the blastodermal anlagen plan. Thus the reduction in the size of anterior structures in the differentiated embryo can be traced back to shrinkage of the corresponding primordia. The abdominal anlage is enlarged and spreads towards the anterior (data not shown).

Localization of bcd^+ activity

We tried to restore the *bcd* function in strong mutant embryos by transplantation of cytoplasm from wild type embryos. Cytoplasm was taken from the anterior tip of young (stage 2)[13] wild type embryos and transplanted into the anterior of mutant embryos of the same age. The amount of transplanted material corresponded to about 5% of the egg volume; one wild type embryo was used as a donor for 1–2 mutant recipient embryos. Nearly all recipient embryos showed a change in phenotype from strong *bcd* towards normal. Some embryos formed only thoracic segments (Fig. 3*b*); others, in addition to thorax, gained almost complete heads (Fig. 3*a*). Three exceptional embryos survived until pupation. The anterior abdomen, which is misshapen in the mutant, became normalized whenever thorax was induced. However, the normal number of abdominal segments was often not restored; new defects arose in the midabdominal region. The embryos were classified according to the degree of anterior development observed (Fig. 4).

The rescuing activity of anterior cytoplasm is strongly dependent on the genotype of the female producing the donor eggs (Fig. 4*b*). Cytoplasm from bcd^- embryos has no rescuing activity. Eggs laid by females with only one bcd^+ gene (*Df* bcd^-/bcd^+), the normal two doses (bcd^+/bcd^+) and three doses of the gene (*Dp* $bcd^+/bcd^+/bcd^+$) have cytoplasm with increasing bcd^+ activity. Varying the amount of transferred cytoplasm mimicks the effect seen with varying bcd^+ gene dosage (Fig. 4*a*), suggesting a linear relationship between bcd^+ gene expression and transplantable activity. This suggests that the bcd^+ gene product might be the active transplanted factor and that no negative feedback acts on its accumulation at the anterior end.

The efficiency of phenotypic rescue decreases with increasing age of both donors and recipients (Fig. 4*c*, *d*). Unfertilized eggs

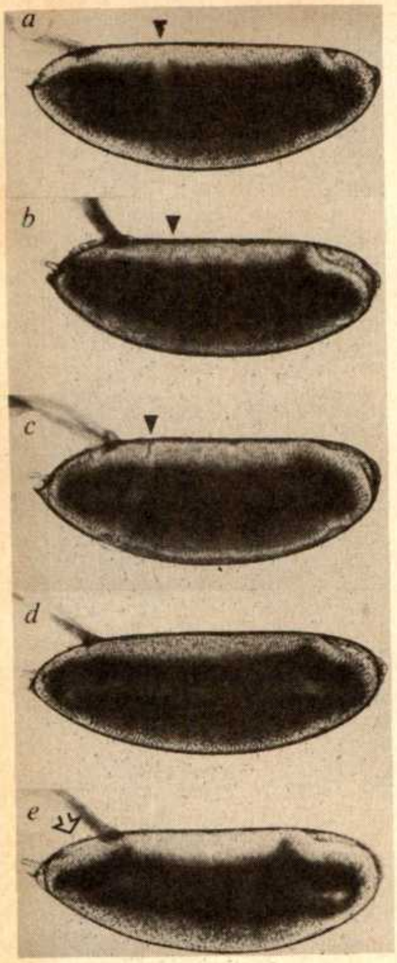

Fig. 2 Gastrulation pattern of mutant embryos. Photographs of living embryos produced by females with: *a*, three bcd^+ copies ($C(1)RM.y$; $T(Y;3)MA9^P/T(Y;3)\ A109^D$)[30,31]; *b*, two bcd^+ copies (wild type); *c*, one bcd^+ copy ($bcd^{GB/+}$); *d*, bcd^{E4}/bcd^{E4}, intermediate allele; *e*, bcd^{E1}/bcd^{E1}, a strong allele. The position of the cephalic furrow (arrowhead) varies with bcd^+ activity between 62% EL (*a*), 65% (*b*) and 71% (*c*). The significance of the backshift in *a* is obscure because females carrying a duplication tend to produce eggs with an unusual shape. Both types of embryos with shifted cephalic folds usually produce normal patterns and survive to adulthood. The cephalic fold is absent in intermediate and strong alleles (*d*, *e*). In the strong phenotype (*e*), a second posterior midgut plate is evident at the antero-dorsal side of the embryo (open arrow). Later in development it performs characteristic invagination movements. Embryos were collected on agar plates, covered with Voltalef 3S oil and photographed in transmitted light with a Zeiss photomicroscope. Anterior left, dorsal at the top.

contain the most active cytoplasm. The activity in older embryos decreases slowly until the last cleavage, after which the activity is sharply reduced (Fig. 4*c*). The high activity observed in unfertilized eggs persists for much longer (data not shown). The responsiveness of recipients decreases continuously (Fig. 4*d*), suggesting that the bcd^+ activity is involved in a process which lasts from fertilization to the end of cleavage.

To determine the localization of the *bcd*-dependent activity in wild-type embryos, cytoplasm was taken from various positions each covering about 10% egg length (EL) along the antero-posterior axis. Figure 4*e* shows that bcd^+ activity is high at the anterior pole and declines sharply away from it, suggesting a graded distribution of bcd^+ activity in the anterior third of the egg. However, the resolution of 10% EL is at the limit of our technique, and a high homogeneous distribution from 85–100% EL would also fit the data. No dorso-ventral difference in activity and no clear difference between central yolk and cortical cytoplasm was obvious. In older donors (syncytial blastoderm), the prevalent anterior localisation is still present (data not shown).

Induction of anterior development

Anterior structures can be induced by injecting bcd^+ activity at any position along the antero-posterior axis. The anterior structures are formed near the injection site. The corresponding reorganization of the pattern involves major changes in embryonic polarity. The abdomen also reorganizes according to the conditions installed by the anterior determinants. The ability of the injected material to induce new thoracic or cephalic structures strongly decreases with distance from the anterior pole (Fig. 5*f*). The posterior pole seems to exert a suppressive force which declines toward the anterior end.

We transferred increased amounts of cytoplasm to compensate for reduced efficiency in induction in the posterior half of the egg. The results are shown together with those of standard experiments in Fig. 5*a*–*f*. We now describe some typical examples of the phenotypes created by heterotopic transplantation, starting with the phenotypic response upon anterior injection.

Even embryos rescued by anterior injection display slight deviations from the phenotypes of the allelic series. They tend to have a rather poorly developed head compared to the thorax (Fig. 3*b*). It may be that when the material is transplanted it is not deposited in the very anterior tip but is spread over an area around 85% EL. If so, the distribution of the activity influences the relative sizes of head and thorax. Injections at 67% EL produced about the same range of phenotypes as anterior injection.

Injection at 50% EL induces head structures near the middle of the injected embryo, flanked by two thoracic regions with opposite polarity (Fig. 3*c*, *e*, *g*). Telson structures characteristic of the mutant phenotype are still present at both poles. A maximum of anterior positional information is thus established near the site of injection in the centre of the egg and decreases in both directions toward the poles. Abdominal segments are only formed at the original posterior site and are frequently reduced in number. The phenotypes suggest that the blastodermal region giving rise to abdomen has been compressed into a very posterior region of the egg.

The asymmetry observed in the embryos is also seen in the inverted region of the induced thorax, which tends to have fewer segments than the one with normal polarity. In the borderline case there is no inverted région in the induced thorax, suggesting a general preference to establish anterior maxima at the terminal region of the egg rather than in the middle. Further, the suppression by posterior factors may primarily affect the posterior portion of the injected material and cause anterior maxima to be established at blastodermal positions somewhat anterior to the site of injection.

Injections to more posterior positions (15% EL and 32% EL) can induce head structures together with three thoracic segments at the posterior end of the egg, the polarity of the entire embryo being reversed. At the same time formation of abdominal segments is strongly suppressed, never leaving more than one field of abdominal denticles. Complete suppression of the abdomen is observed more frequently after injection at 32% EL than at 15% EL (Fig. 5*a*–*f*), suggesting that *bcd*$^+$ activity probably does not act on the posterior pole plasm to suppress abdomen specific factors[9]. Rather it appears to act on a signal spreading from the pole or to share common targets with this signal.

When abdominal segments are formed in phenotypically less extreme animals, the posterior segments have inversed polarity. Figure 3*d*, *f* shows an embryo in which, in addition to producing thoracic structures, two inversed abdominal segments were formed, the posterior one having the appearance of a first abdominal segment. As the anterior activity cannot induce abdominal development on its own, it must have modified the action of some abdomen specific factors. Such an interaction would ensure a continuous change of morphological values at the boundary of thorax and abdomen.

Phenocopies by cytoplasm removal

The *bcd* phenotype can also be produced (phenocopied) by elimination of anterior cytoplasm. Pricking the anterior end of wild type eggs (stage 2) to allow leakage of ~5% volume mainly generates embryos with reduced head structures, resembling weak *bcd* phenotypes (Fig. 6*a*). Treating embryos in which *bcd*$^+$ activity is already reduced causes stronger *bcd* phenocopies approaching the amorphic phenotype (Fig. 6*b*, *c*). Strong mutant embryos do not show any change on loss of anterior cytoplasm (Fig. 6*d*). The artificial phenotypes also show abdominal defects suggesting that the entire *bcd* phenotype is caused by the lack of anteriorly localized cytoplasmic activity. Pricking preblastodermal eggs at non-terminal sites does not eliminate cuticular pattern elements, whereas leakage at the posterior pole with removal of the posterior pole plasm causes abdominal defects resembling weak *oskar* phenotypes[6]. In *Smittia*, in contrast to *Drosophila*, anterior pricking creates bicaudal embryos with a reversed abdomen at the anterior[14]. This difference reflects a general tendency in *Smittia* to produce symmetrical states, if one terminal activity is not balanced by its antagonist.

Conclusions

Mutant *bcd* embryos fail to produce head and thorax. Corresponding primordia do not appear in the anlagen plan at the blastoderm stage. Instead a second telson is found at the anterior end and the abdominal primordium is expanded towards the anterior. The *bcd* phenotype is thus composed of two types of defect; loss of anterior structures due to shrinkage of the anlagen

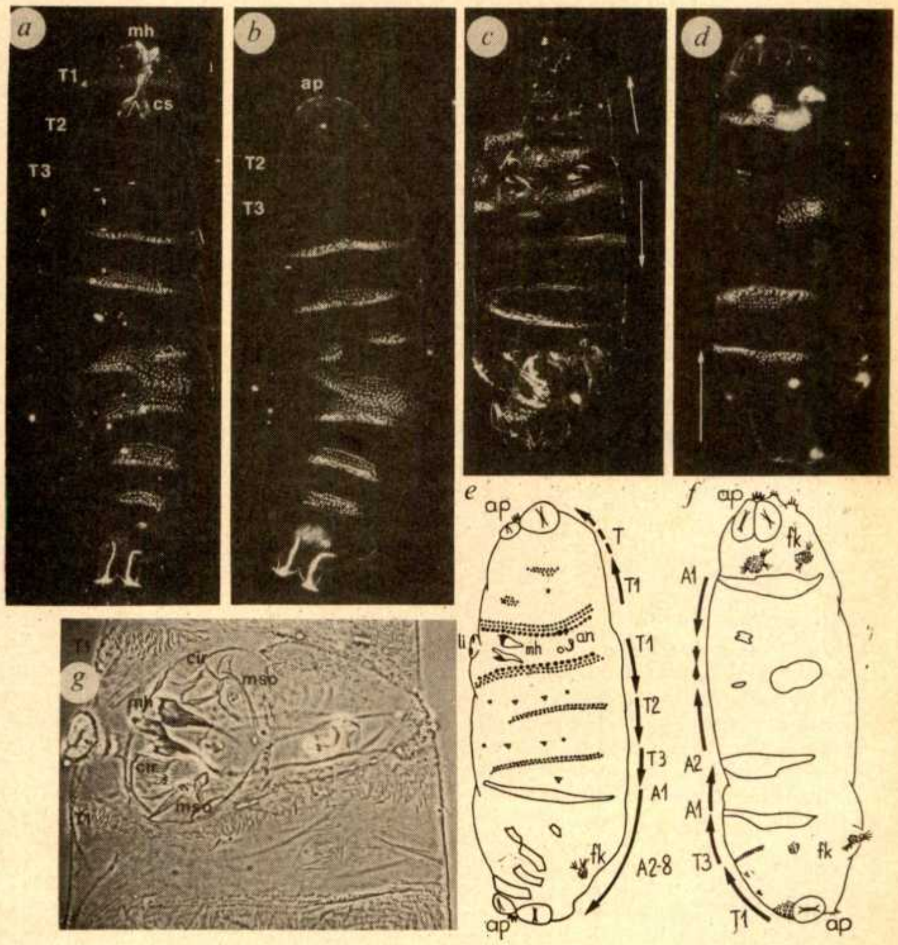

Fig. 3 Phenotypes of *bcd*$^-$ embryos injected with anterior cytoplasm. *a*, *b*, Strong and weak response to anterior injection. The embryo in *a* has gained all anterior structures with the exception of the labral derivatives (median tooth and dorsal bridge). Note that the anterior abdominal region is also normalized; but mid-abdominal segments are fused, a type of defect not seen in non-injected controls. The embryo in *b* developed two thoracic segments, but no head structures; small anal plates are retained at the anterior. In the phenotypic series, embryos with more than one thoracic segment also have some remnants of head structures (compare Fig. 1*c*). Moreover injected embryos display T2 and T3, but the denticle belt of T1 is the most stable to mutation. These discrepancies are interpreted as being caused by a subterminal and less compact positioning of the activity in the injected animals. *c*, *e*, *g*, Embryo after injection at 50% EL. The induced cephalic structures are flanked at the anterior and at the posterior side by thoracic regions of opposite polarity. Most of the head structures are formed at the dorsal side of the embryo (shown in detail in *g*). Mainly maxillary derivatives can be recognized. In this type of embryo, the head is not oriented along the antero-posterior axis of the egg; cephalic structures frequently have dorsal or lateral positions and their sequence seems to be delineated tangentially along the circumference of the egg within a transverse plane. The transverse plane is the plane of bilateral symmetry seen among the head structures. Sometimes pairs of head structures occur at either side of the embryo, (4 mouth hooks, 4 maxillary sense organs and/or 4 groups of ventral cirri in total). Due to cuticular holes and the scarcity of characteristic structures other than those of the maxilla the anteroposterior polarity of the head is difficult to assess. Possibly the anterior end of the head lies either dorsally or ventrally depending on the localization of the injected cytoplasm. *d*, *f*, Embryo injected at 15% EL. Two bands of thoracic denticles have been induced at the posterior. They are the anteriormost elements of an inversed region including about 2.5 abdominal segments. Anteriorly the original abdominal polarity is preserved. The appearance of a new A1 shows that not only the polarity but also the quality of abdominal segments has been changed. The posterior telson is partially suppressed. Arrows, segment polarity; polarity is ambiguous in the case of the broken arrow in *e*. Black dots and triangles, thoracic sensory organs. Identification of labial (li) and antennal (an) structures is not certain in the specimen in *e*. cir, cirri; mso, maxillary sense organ. Other designations as for Fig. 1.

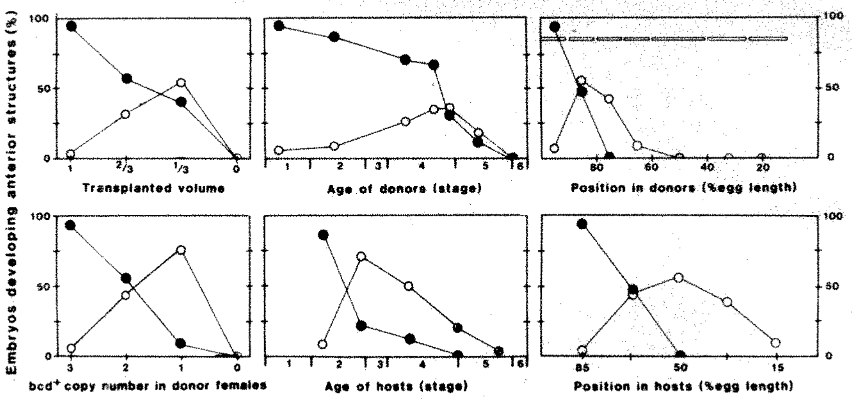

Fig. 4 Phenotypic response on cytoplasmic injection. Frequencies of embryos induced to develop thoracic and cephalic structures (●, strong response) or displaying thoracic structures only (○, weak response) provide a measure for efficiency of induction obtained under various experimental conditions. Females carrying a duplication for bcd^+ produced the donor eggs and the recipients were from bcd^{E1}/bcd^{E2} females unless otherwise indicated. Donor eggs were of stage 1 or 2 in *d* and unfertilized elsewhere; recipient eggs were of stage 1 or 2. Cytoplasm was withdrawn from an anterior area (80–100% EL). When injected into an anterior position it was observed to spread in the central core of the egg between 75 and 95% egg length. The amount of cytoplasm transferred was about 5% of the egg volume. Average number of embryos for each point was 33 (range 13–54). *a*, The usual amount of injected cytoplasm is set to 1 arbitrary unit. The different relative volumes (1, 2/3, 1/3) were achieved by counting the time cytoplasm was allowed to flow from the needle into the egg (15 s, 10 s, 5 s respectively). *b*, Donor females were of the genotypes $bcd^+/bcd^+/bcd^+$ $(T(Y{:}3)MA9^P/T(Y{:}3)\ A109^D)$, wild type, $bcd^-/+(Df(3R)9A99/+)$, and bcd^{E1}/bcd^{E2} with bcd^+ copy number decreasing from three to zero. *c*, *d*, Stages as described in methods. Unfertilized eggs are taken to represent the youngest stage 1 in *c*. In old recipients (stage 5) despite the low frequency of induction affected animals mostly display some remnants of head structure surrounded by few thoracic denticles (●). *e*, Bars on top represent the areas from where cytoplasm was withdrawn. *f*, Further information about the phenotypes obtained in this experiment is provided in Fig. 5*a*–*c*.

Methods. Eggs were dechorionated with NaOCl and attached to a sticky cover slip. Recipient embryos were dried for 10–12 min with a fan, both donors and recipient eggs were then covered with halocarbon oil (Voltalef 10S). Injections were performed under a compound microscope. Micropipettes of about 12 μm external diameter driven by a syringe were used. Recipient eggs were entered by the micropipette at the anterior pole in most cases, sometimes from the side but never from posterior in order to avoid loss of the posterior pole plasm. To assess the amount of cytoplasm transferred, the entire content of an egg was drawn into the needle. About 20 recipient embryos could be injected using one donor embryo. Cytoplasm which leaked out during injection was removed afterwards. Experiments were performed at 18 °C or 20 °C. Usually about 80% of injected embryos differentiated cuticle and could be scored. The stages are those of Campos-Ortega and Hartenstein[13] (1, freshly laid egg; 2, early cleavage; 3, pole cell formation; 4, syncytial blastoderm (nuclear cycle 10–13)[32]; 5, blastoderm cellularization; 6, gastrulation). All embryos were staged visually during injection; young and old stage 2 embryos in *d* were distinguished by the time they entered gastrulation.

and abdominal segmentation defects in a stretched posterior domain. The action of bcd^+ on both the anterior and abdominal region is mediated by the anteriorly localized activity. The anterior centre thus influences the pattern of more than half of the egg length in spite of its striking anterior localization. The structures of the telson occupy the terminal positions in the egg if there is low bcd^+ activity, irrespective of which other structures become their neighbours.

The amount of bcd^+ activity present in the egg determines the size of cephalic and thoracic anlagen. It also affects the degree of anteriorness in the cuticular structures. The exact positioning of the bcd^+ dependent activity seems to influence the relative preponderance of thoracic and cephalic elements in homotopic transplantations. Changes of polarity associated with heterotopic transplantations provide more striking evidence that the bcd^+ activity not only establishes the anterior primordium but also controls its internal organization. Describing the action of *bcd* therefore requires more than one spatial parameter. The production of different anterior qualities depending on quantity and distribution of bcd^+ activity is best explained by assuming a graded distribution of factors determining the positions of head and thorax. The well organized polarity observed in the cuticle of injected embryos contrasts with the coarse conglomeration of activity present immediately after transplantation. The

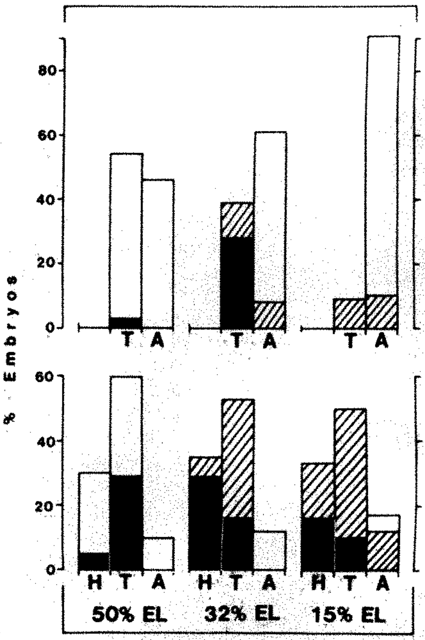

Fig. 5 The effect of heterotopic transplantation on abdomen formation. The standard volume (*a*, *b*, *c*) or 1.5× standard volume (*d*, *e*, *f*) of anterior cytoplasm was transplanted into three different positions at 50% EL (*a*, *d*). 32% EL (*b*, *e*) and 15% EL (*c*, *f*) of bcd^{E1}/bcd^{E2} embryos; other conditions were as described for Fig. 5. On an average 35 embryos have been recorded for each panel. Columns in each panel show the frequency of embryos with head and thoracic structures (H), only thorax (T), or neither of the two (A, abdomen). The marked areas in each column indicate the behaviour of the abdomen occurring in each class. Black portion, embryos with complete abdominal suppression (without abdominal denticle belts); hatching, cases in which inversed abdominal segments have been induced; white, the remainder of the embryos with an abdomen (partially suppressed or not). The phenotype expressed may depend on whether the transferred cytoplasm happens to be closely centred around the injection site or spreads some way through the egg. A certain amount of cytoplasm may be sufficient to induce head if centred well at 50% EL, but will then not suppress the abdomen very strongly. If the same amount of cytoplasm induced only thorax, abdominal suppression was much stronger suggesting less restricted localization (*d*). In many of the embryos displaying thorax only, segmental organization was poor and polarity was disordered. Otherwise we observe the expected positive correlation between transplanted volume, extent of anterior inductions, and suppression of abdomen. Abdominal suppression is most effective at 32% EL, whereas abdominal inversion is obtained with higher frequencies at the posteriormost injection site. The differences between the three sites tend to decrease with higher amounts of transplanted cytoplasm, probably due to lower spatial resolution. Once the threshold of posterior inhibition is overcome, anterior induction may be favoured in terminal positions. On transferring large volumes of cytoplasm, frequencies of polarity reversal within induced anterior regions varied with the site of injection thus: 2% (85% EL), 12% (67% EL), 55% (50% EL), 6% (32% EL), 5% (15% EL).

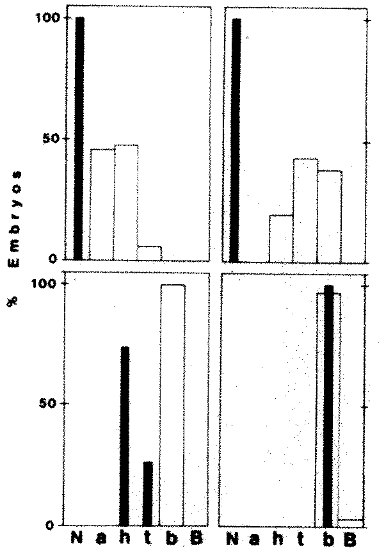

Fig. 6 *a–d*, Production of *bcd* phenocopies by removal of cytoplasm. The phenotypic response upon pricking and subsequent leakage of anterior cytoplasm from different genotypes is shown. Maternal genotype of pricked eggs: *a*, wild type; *b*, $Df(3R)9A99/+$: *c*, bcd^{E3}/bcd^{E3}; *d*, bcd^{E1}/bcd^{E2}. The letters along the abscissa designate the phenotypic classification. N, essentially normal; a, head weakly reduced with antenna still present; h, head strongly reduced; t, thorax reduced (head reduced or absent, usually some telson structures duplicated); b, head and thorax entirely absent, mimicking the bcd^- phenotype; B, some abdominal segments inversed reminiscent to *Bicaudal* (only 1 case). Black columns, phenotypic spectrum of untreated embryos; white columns pricked embryos. Removal of anterior cytoplasm causes a shift toward the amorphic phenotype. Treating amorphic mutant embryos elicits no further change (for example, toward bicaudal embryos).

Methods. Embryos were mounted as in transplantation experiments, but not dried. Anterior pricking caused loss of cytoplasm (5% egg volume), which was carefully removed from the outside of the eggs. About 70% of the embryos survived to the differentiated stage[6]. At least 30 embryos have been recorded for each panel.

transplanted activity may achieve some redistribution, but we feel that it probably acts as a localized source providing a spreading signal to instruct the peripheral sheet of nuclei. This might explain why the position of the transplanted material is crucial for the eventual phenotype but is not necessarily isomorphic with the pattern induced. An anteriorly localized RNA transcribed from the *bcd* locus and distributed similarly to our transplantable activity has been found[15]. The translation product may be the postulated signal.

The spatially restricted expression of zygotic segmentation genes of the 'gap' class might be the focus of *bcd* function in the anterior half of the embryo[3,16]. Gap mutants eliminate continuous blocks of segments (or parasegments[17]) along the body axis[18–20]. In contrast to the *bcd* phenotype, the anlagen plan outside the regions deleted suffers no major alterations[20–22]. In *hunchback* mutants, labium and thorax (the posterior part of the *bcd* domain) are lacking[20]. Therefore there may be no expression of *hunchback* in *bcd* embryos. Mutants in *Krüppel* (*Kr*) eliminate segments T1–A5, segments which are dependent on the function of *bcd*, as well as segments dependent on *oskar*. *Kr* should therefore be expressed in both *bcd* and *osk* embryos. However, the abdominal expansion seen in *bcd* embryos suggests an anterior shift in the spatial expression of *Kr*.

Abdominal development is strictly dependent on maternal genetic functions as exemplified by the gene *oskar*, which has been examined by means quite similar to our own work on *bcd*[9]. In controlling the posterior pole plasm and abdominal development, *oskar* and its relatives[7,8] constitute a posterior analogue to the function of *bcd*. However the interplay between *bcd* and *oskar* dependent factors is not symmetric. Anterior anlagen show no major expansion towards the posterior in *oskar* embryos[9,33], so the establishment of the anterior *bcd* domain is independent of the posterior centre. But an antagonistic effect can be provoked experimentally; when posterior pole plasm is transplanted to the anterior tip of wild-type eggs it suppresses anterior development[6,9]. Anterior cytoplasm transplanted into the range of the future abdomen is weakened in its inductive strength (Fig. 4*f*). Because the anterior source material seems to be outside the range of inhibiting posterior factors in wild-type eggs, there is no obvious natural function for such an interaction during postfertilization stages, when both polar centres are already established.

The bcd^+ gene is not required to establish abdominal anlagen as such but is required to confine abdominal development to the posterior half of the embryo. Depending on position, bcd^+ activity can drive abdominal primordia backwards in the blastodermal anlagen plan; change abdominal segmental qualities toward more anterior values; or suppress abdominal development. Thus bcd^+ exerts profound interventions on structures which develop fairly autonomously in bcd^- embryos. If one assumes abdominal development to be organized by a posterior gradient emanating from the pole plasm[23], then inhibition and modification of this gradient by *bcd* dependent activity would explain all types of interactions described here. Alternatively, *bcd* might not act on maternally encoded factors and contribute nothing to abdominal development other than to determine its anterior boundary by control of *Kr* gene expression.

We thank Ruth Lehmann for discussions and Kavita Arora, Thomas Berleth, Stephen Cohen, Martin Klingler, David Marcey and Siegfried Roth for helpful suggestions on the manuscript. Ruth Lehmann, Kathryn Anderson and Gerd Jürgens participated in the mutant screens that led to the isolation of the *bicoid* alleles. We thank Gunilla Weinraub for drawings, Roswitha Groemke-Lutz for the photographic prints, and Dominique Kaiser for typing the manuscript.

A parallax effect due to gravitational micro-lensing

B. Grieger, R. Kayser & S. Refsdal

Hamburger Sternwarte, Gojenbergsweg 112,
D-2050 Hamburg 80, FRG

The astrophysical importance of gravitational micro-lensing due to stars in the deflecting galaxy is now well-known[1–7]. Each macro-image (caused by the corresponding smoothed-out galaxy) can be split up into several micro-images with typical angular distances measured in micro-arcseconds. Here we discuss a parallax effect due to gravitational micro-lensing (star disturbances). We show that such an effect would most favourably be observed during high amplification events when a compact source (quasar) crosses a critical curve. During such an event even a relatively small displacement (≥0.1 AU) of the observer may lead to measurable differences in the image brightness. We discuss this parallax effect with special emphasis on the determination of (1) the size of the quasar and (2) the relative transversal velocities involved. It should be possible to observe such a parallax-effect with a relatively small telescope (10–20 cm) included in an interplanetary mission. In extreme cases, annual oscillations in the light curves of lensed quasars can be observed from the Earth, but in most cases these oscillations can be neglected.

Of particular interest among instances of gravitational micro-lensing are the high amplification events[2] that occur when a compact source crosses a critical curve[1]. These high amplification events where $\Delta m \approx 3$ are suddenly initiated (or terminated) by the appearance (or disappearance) of two bright micro-images[1,4,5]. It is a kind of 'gravitational eclipse' effect, allowing the formation of large spatial magnitude gradients and the occurrence of very fast changes in the observed brightness due to transverse motion (grad $m \approx 0.3$ AU^{-1} and $\partial m/\partial t \approx 0.1$ day^{-1} for a source radius of 10^{-4} pc and a typical transverse velocity of 500 km s^{-1}). The frequency of such high amplification events has been estimated[2] to be about 0.3 per year for all known gravitationally-lensed quasars. The time scale of such events is given approximately by the diameter of the source divided by the transverse velocity V_T of the source relative to the critical curve in the source plane. We note that V_T is equivalent to a relative transverse velocity (v_T) between the observer and the critical curve in the observer plane

$$v_T = -V_T \frac{D_d}{D_{dq}}(1+z_d) \tag{1}$$

where D_d and D_{dq} are apparent size distances and z_d is the redshift of the deflector. Because the critical curves have a radius of curvature of the order of one normalized length unit[2] ($\sim 10^4$ AU for solar mass stars), we can approximate the critical curves by straight lines inside the solar system. We can also assume that the observed luminosity of a point source locally only depends on the distance d to the critical curve ($\propto d^{-1/2}$)[1,4,8].

During a high amplification event, the observed brightness changes very rapidly, and even a small displacement of the observer can bring about measurable changes. During a typical event ($\Delta m \approx 3$), a displacement of only 0.1 AU (perpendicular to the critical curve) in the plane of the observer leads to a change in brightness of up to $\delta m \sim 0.025$ for a typical lensed quasar ($D_d \approx D_{dq}$ and a source radius of 10^{-4} pc). (For the somewhat untypical lens object OSO 2237+0305 ($D_{dq}/D_d \sim 10$), $\delta m \sim 0.25$.)

This parallax effect raises the possibility of calculating v_T from observations made by three observers some distance apart (see Fig. 1). If the time lags δt_{AB} and δt_{AC} in the light curves are known, we can eliminate the angle β and determine the relative transverse velocity v_T (perpendicular to the critical curve) in the observer plane:

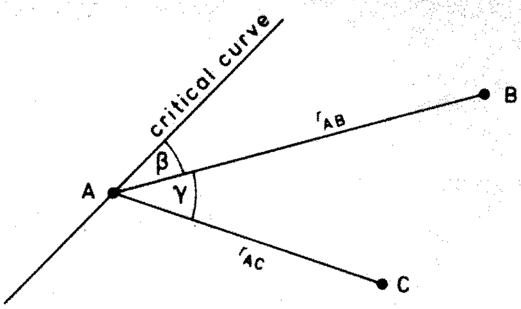

Fig. 1 Position of 3 observers, projected onto the observer plane.

$$v_T = |\sin\gamma| \left\{ \left(\frac{\delta t_{AB}}{r_{AB}}\right)^2 + \left(\frac{\delta t_{AC}}{r_{AC}}\right)^2 - 2\cos\gamma \frac{\delta t_{AB}\,\delta t_{AC}}{r_{AB}r_{AC}} \right\}^{-1/2} \tag{2}$$

Here we have made use of the fact that the time lags δt are equal to the time differences across the critical curve.

From equation (1) we obtain the corresponding velocity V_T in the source plane. From the typical time scale Δt of the high amplification event, we can then determine the time needed by the source to cross the critical curve, and thereby the radius $R = k\Delta t/V_T$ of the source, where k (≈ 1) depends on the luminosity profile of the source and the amplitude of the event. This will be discussed in a subsequent paper.

If there are only two observers, A and B, a straightforward relation between the two unknowns v_T and $\sin\beta$ emerges (see Fig. 1).

$$v_T = r_{AB}\sin\beta/\delta t_{AB} \leq r_{AB}/\delta t_{AB} \tag{3}$$

We thus see that with only two observers an upper limit of v_T is obtained.

Because reliable determination of the time lags does not require very exact observations we propose that a rather small telescope (diameter 10 to 20 cm) would be sufficient in the case of the brightest multiple quasars where $m \approx 17$. In view of the very important information that could be obtained the possibility of sending such a telescope in an interplanetary mission should be investigated.

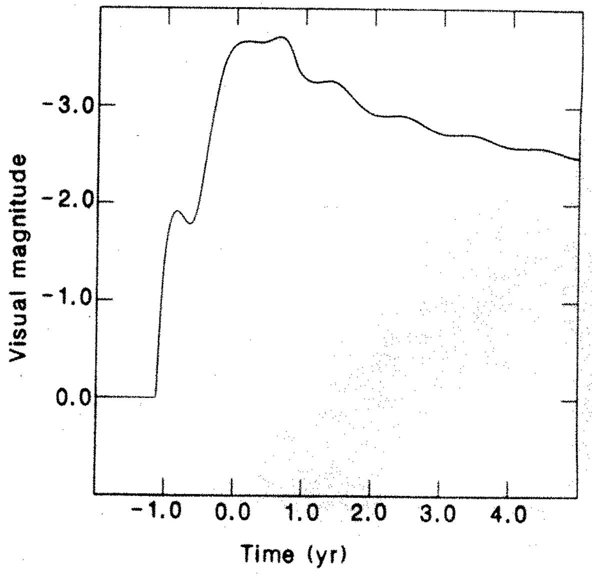

Fig. 2 Simulated light curve of a high amplification event in the lens object 2237+0305, showing oscillations due to the annual motion of the earth.

Considering the sighting of the somewhat improbable lensing by a double star[9,10] in our galaxy ($D_{dq} \approx 10^7\ D_d$), a parallax effect could possibly be observed by Earth-bound observers. During the most rapid variations, an observer displacement of only 6 km results in a brightness change of up to about 0.1 mag. The time scale of the high amplification event would then typically be measured in seconds.

Another possible application of the parallax effect would be to make use of the annual motion of the Earth. For an Earth-bound observer the distance $d(t)$ to the critical curve in the observer plane varies (1) due to the transverse velocity of the solar system relative to the critical curve and (2) due to the annual motion of the Earth. We note that the position of the Earth projected onto the plane of the observer is determined by the celestial coordinates of the observed object.

Figure 2 shows a simulated light curve for the lens object 2237+0305, which because of the large value of D_{dq}/D_d (~10) gives the best chance of observing the effect. Here we have used a dimensionless surface density of continuously-distributed matter of $\sigma_c = 0.8$, a Hubble parameter of $H_0 = 75\ \mathrm{km\ s^{-1}\ Mpc^{-1}}$ and a standard cosmological model ($q_0 = \sigma_0 = 0$). The source has a radius $R = 2.7 \times 10^{-4}$ pc and a luminosity profile $I(r) = I_0 (1-(r/R)^2)^{1/2}$. This seems to be more reasonable than $I(r) =$ constant and has the advantage of leading to an analytical solution of the mean amplification $\langle A(\mathrm{d})\rangle$. The change in brightness is given by $m(\mathrm{d}) = -2.5 \log \langle A(\mathrm{d})\rangle$. We further assume a transverse velocity of one source radius per year, that is $260\ \mathrm{km\ s^{-1}}$ in the source plane or $25\ \mathrm{km\ s^{-1}}$ in the observer plane. The annual motion of the Earth shows up clearly in the light curve as an oscillation (Fig. 2). It is clear that observable effects only occur if (1) the transverse velocity of the solar system relative to the critical curve is smaller than or about equal to the orbital velocity of the Earth ($v_T \leq 50\ \mathrm{km\ s^{-1}}$ and (2) the projection $\tilde{R}$ of the source radius R onto the observer plane is not too great ($\tilde{R} \leq 100$ AU). The first condition is particularly unlikely to be fulfilled, because a typical transverse velocity in the observer plane is of the order of $500\ \mathrm{km\ s^{-1}}$. It therefore seems safe in most cases to neglect the annual parallax effect by gravitational micro-lensing, even during the high amplification events.

Companion star of a binary millisecond pulsar

G. A. Wright & E. D. Loh

Department of Physics and Joseph Henry Laboratories, Princeton University, Princeton, New Jersey 08544, USA

Binary pulsars offer important clues about the evolution of neutron stars. We have searched for and identified the companion star of the recently discovered[1] binary millisecond pulsar PSR1855+09. The optical counterpart is compatible with a $0.3M_\odot$ white dwarf with a surface temperature of ~5,900 K. This is in accord with currently accepted ideas on the genesis of such a fast binary pulsar[2]. The low temperature of the white dwarf implies that the system is $>10^9$ yr old. Such an old pulsar is not easily accounted for by the conventional theory, in which the pulsar ceases to be active after its magnetic field decays, a process believed to take ~10^7 yr.

In February 1986, an accurate position was obtained for PSR1855+09 by Fruchter using the Very Large Array (VLA)[1]. Shortly afterwards, we began to look for the companion of this pulsar. Observations were made in April 1986 with the 2.3-m telescope at the Wyoming Infrared Observatory. Pictures were taken using the Princeton charged coupled device (CCD) camera at the $f/2$ prime focus. The field of view is 7 × 10 arc min and the plate scale is 1.23 arc s per pixel. For the observations of PSR1855+09, 500- and 700-nm bandpass filters were used (each ~100-nm wide), corresponding roughly to the V and R bands.

Nine exposures were made over two nights in the 700-nm band. Of these, the three pictures with the best seeing were averaged and the result used for photometry. Seven 500-nm exposures were taken on one night and the best two averaged. All exposures were 300 s long. Sky transparency was good during the observations. The seeing in the best 700-nm frames is 2.5 arc s (full width at half maximum, FWHM) and 3.0 arc s in the 500-nm frames. The inferior seeing in the 500-nm pictures is due in part to strong, gusty winds during those exposures. The telescope was moved slightly between exposures to avoid always putting the candidate star close to any defective pixels on the CCD.

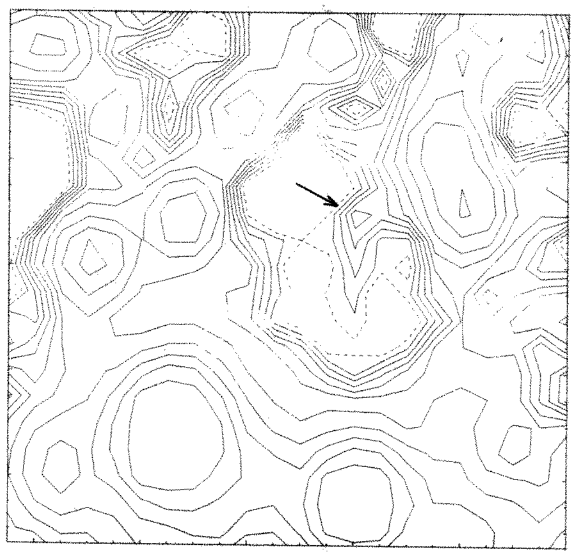

Fig. 1 Isophot plot of the 700-nm-CCD frame of the companion of PSR1855+09. East is up and north is to the right. The arrow indicates the position of the object. The area shown is 27 × 27 arc s. The contours are linearly spaced for low intensities changing to logarithmic at high intensities. The lowest intensity contour is dashed. The west pointing 'tail' near the marked object is caused by a very faint ($m_{700} \simeq 24$) star visible in the best seeing 700-nm frame. The two bright objects at the western edge of the field are $m_{700} \simeq 17.5$ stars visible on Palomar Sky Survey plates.

The candidate star for the companion of PSR1855+09 is shown in Fig. 1. Its peak intensity in the 700-nm frame shown is 7σ above the noise (detector noise plus sky noise). In the poorer seeing 500-nm frame, the peak is 3σ above the noise. The indicated star corresponds, within astrometric error, to the VLA position of PSR1855+09 listed in Table 1. (Error in astrometry is estimated to be ±0.9 arc s in both right ascension and declination.) It is in a dense field of stars, only 3° away from the galactic plane. The number of stars in the field was

Right ascension (1950.0)*	$\alpha = 18$ h 55 min 13.681 s $\pm$ 0.006 s
Declination (1950.0)*	$\delta = +09° 39' 13.39'' \pm 0.09''$
Pulsar period*	$P = 5,362,100,452.5 \pm 0.3$ ps
Orbital period*	$P_b = 1,065,067.49 \pm 0.03$ s
Dispersion measure distance*	$d \simeq 350$ pc
Companion mass*	0.2-0.4$M_\odot$
Pulsar magnetic field*	$B = (3.4 \pm 0.4) \times 10^8$ G
Companion apparent magnitude	$m_{700} = 22.01 \pm 0.10$
	$m_{500} = 22.65 \pm 0.15$
Companion temperature	$T = 5,900^{+1,400}_{-1,000}$ K

* Data from ref. 1.

counted to estimate the probability of a chance coincidence. The measured density of stars gives the probability for the centroid of any star to be within 1 pixel of the indicated position of $\leq 5\%$.

Data reduction and photometry were done using the Princeton Stargaze picture processing system. Photometry is complicated by the fact that the candidate star lies in the wings of a pair of nearby bright stars. These stars were fitted by gaussians and subtracted from the pictures. A 3.7 × 3.7 arc s aperture was centred on the candidate and its intensity measured. A relatively small aperture was chosen to exclude light from other nearby stars. The light falling outside the aperture was estimated by photometry of calibration stars and the intensity was corrected for this. The resulting intensities were converted into AB_{79} system magnitudes using the flux standard stars BD+26 2606 and HD84937 (ref. 3). (AB_{79} magnitudes are relative to a fictitous star whose spectrum is flat in frequency. $m_{AB} = 0$ corresponds to a flux density of 3.65×10^{-20} erg s^{-1} cm^{-2} Hz^{-1}.) The apparent magnitudes are listed in Table 1. Most of the error is due to the uncertainty in the background level of such a crowded field of stars. Other errors come from sky and readout noise and possible errors in centring the photometry aperture. The colour index $m_{500} - m_{700}$ is 0.6 ± 0.2.

The candidate star must be a degenerate star. Main-sequence stars with the observed flux ($m_{700} = 22.0$) in the galactic plane are redder than $m_{500} - m_{700} = 2.3$, because intrinsically blue stars must be distant and highly reddened. Degenerate stars at the same apparent magnitude are ~100 times closer and therefore suffer less reddening. The probability of a degenerate star being with 1 pixel of the pulsar position is $<10^{-4}$ (ref. 4). Therefore we conclude that the star indicated in Fig. 1 is the companion of PSR1855+09.

The temperature of the companion star can be estimated from the colour index. Using the dispersion measure distance obtained by Segelstein *et al.*[1] of 350 pc and taking a value for interstellar absorption of $A_V = 1.9$ mag kpc^{-1} (ref. 5), we get a corrected colour index $m_{500} - m_{700} = 0.3 \pm 0.2$. Dispersion measure distances are typically accurate to 50%, although in some cases they may be off by a factor of two or more[6]. (The error given includes a 50% uncertainty in distance.) The corrected colour index corresponds to a temperature of $5,900^{+1,400}_{-1,000}$ K.

From pulse arrival time measurements, Segelstein *et al.*[1] have estimated the mass of the companion of PSR1855+09 to be 0.2-0.4 solar masses. The observed object is consistent with a white dwarf of $M = 0.3M_\odot$, $R = 0.02R_\odot$, and $T = 5,900$ K at a distance of 475 pc, which agrees with the 350 pc dispersion measure distance.

That the companion star is so cool indicates that the PSR1855+09 system is very old. The characteristic cooling time for a $0.3M_\odot$ white dwarf is 2×10^9 yr (ref. 7). The age of the pulsar, whose progenitor evolves off the main sequence earlier than the white dwarf's, must be greater than this. The pulse period of PSR1855+09 is 5.4 ms. An old pulsar spinning so fast must have been spun up by angular momentum transfer from the companion. Our evidence supports the conventional hypothesis that millisecond pulsars are recycled, that is they are old neutron stars whose large angular momentum is due to mass accreted from a companion star.

A similar low-temperature white dwarf was observed in the PSR0655+64 system by Kulkarni[8]. The existence of such an old yet still active pulsar is at odds with the naive notion of magnetic field decay in pulsars[9], which would switch them off after $\tau_{\text{magnetic}} \simeq 10^7$ yr. Kulkarni proposes that the pulsar magnetic field has two components, one that decays in a timescale of 10^7 yr and a residual nondecaying field. Under some circumstances, the residual field may be sufficient for the pulsar to remain active for much longer than τ_{magnetic}.

Measurement of the pulse period derivative yields an estimate of the surface magnetic field of a pulsar[10]. The timing data[1] for PSR1855+09 gives a field of $(3.4 \pm 0.4) \times 10^8$ G. Because the age of the pulsar is 100 times the field decay time, the present field is a good candidate for a nondecaying remnant field. The other millisecond pulsars, PSR1937+21 and PSR1953+29, have surface fields within a factor of two of this value. These three pulsars have the smallest magnetic fields measured. Whether this represents a lower limit on pulsar magnetic fields is an interesting question awaiting more data.

We thank the director and staff of the Wyoming Infrared Observatory for telescope time and assistance. Earl Spillar helped us make the observations. Andy Fruchter, Lloyd Rawley, Dan Stinebring and Joseph Taylor supplied much useful information and made many helpful comments. This work was supported in part by the NSF.

An explanation for fast downflows on the Sun

The discovery of coronal loops has provoked major revisions in the theory of solar and stellar atmospheres. The solar corona is now recognized as a highly structured plasma, organized by bundles of intense magnetic field into individual arch- and loop-like structures along which gas can flow[1]. Each arch, rooted in the solar interior, extends through the chromosphere ($T < 10^4$ K), and generally contains coronal plasma ($T > 10^6$ K) in its upper reaches. Early attempts at explaining the temperature and density structure of isolated static loops met with considerable success, despite the simplicity of the theory[2,3]; however, attempts to generalize the theory to describe loops with mass flows have remained singularly unsuccessful[4-9]. Here we point out that the puzzling observational properties of loop mass flows[10-15] can be naturally explained if the loop is sufficiently cool ($T \lesssim 10^6$ K)—that is, if it contains no coronal plasma.

Observed flows exhibit several features that must be explained by any convincing theory. First, the flows are observed to persist much longer than the transit time of a gas element through the

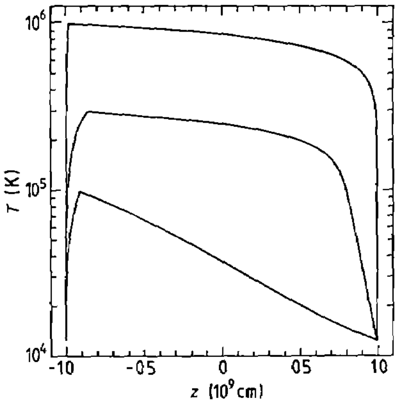

Fig. 1 Temperature profile in a loop of length 2×10^9 cm (z is the distance along the loop) with a steady flow of 5 km s^{-1} at 10^5 K, for peak temperatures of 10^5, 3×10^5 and 10^6 K. The corona is heated by a point energy source (at the position of maximum temperature). Extreme asymmetry is required to drive flows of the observed magnitude, 5–10 km s^{-1} at 10^5 K.

loop[10,11]. This fact alone suggests a quasi-steady model in which plasma flows continually from one footpoint to the other. This model also readily accounts for the second observed property, namely, that emission from the downflowing leg predominates[10-15]. This can be understood as a consequence of the asymmetry of the temperature profile[9] induced by steady flow (see Fig. 1). Altogether more tantalizing, however, is the third property: flow speeds are large (5–10 km s^{-1}) at transition-region temperatures ($T\simeq10^5$ K), yet the flows apparently disappear at coronal temperatures[11-14]. This feature appears completely inexplicable in terms of current steady flow models. The problem arises because, on the assumption of subsonic flow, the pressure $P=2\rho RT$ should be nearly uniform, which, together with the steady-state condition of constant mass flux $q=\rho v$, implies $v\propto T$. It follows that in typical loops the highest velocities are to be expected at coronal temperatures, namely $T\geq10^6$ K.

The key to this paradox lies in momentum conservation. When the flow velocity approaches the sound speed, the dynamic pressure, $\rho v^2\equiv qv$, becomes important, forcing the gas pressure to decrease. The net result is an upper limit on the coronal temperature for a given flow speed (see equation (3) below).

To illustrate the problem in the simplest possible way, we neglect gravity and assume a loop of uniform area. Then the steady flow momentum equation implies

$$qv+P=qv_0+P_0 \tag{1}$$

where subscript zero denotes conditions at a reference point. As the dynamic pressure qv increases, the gas pressure P must decrease. Eliminating $\rho=q/v$ from equation (1) and writing $M=v/c$ for the Mach number relative to the isothermal sound speed $c=\sqrt{2RT}$, we can solve for temperature, obtaining

$$\frac{T}{T_0}=\frac{v}{v_0}\left[(1+M_0^2)-M_0^2\frac{v}{v_0}\right] \tag{2}$$

For subsonic flow ($v\ll c$), equation (2) reduces to the familiar hydrostatic condition of uniform pressure, $v/v_0=T/T_0$. But at higher flow speeds the function $T(v)$ is a parabola, with a turning point at (v^*, T^*), where

$$\frac{v^*}{v_0}=\left(\frac{1+M_0^2}{2M_0^2}\right),\qquad \frac{T^*}{T_0}=\left(\frac{1+M_0^2}{2M_0}\right)^2 \tag{3}$$

which occurs when the flow speed reaches the isothermal sound speed.

This turning point defines the maximum possible temperature T^* in the loop. Setting $T_0=10^5$ K and noting that for $v_0\lesssim10$ km s^{-1}, $M_0^2\ll1$, we obtain from equation (3)

$$T^*\simeq(20/v_0)^2\times10^5\ \mathrm{K} \tag{4}$$

with v_0 in km s^{-1}. It is clear that higher loop temperatures correspond to lower flow speeds. For v_0 in the range 5–10 km s^{-1}, equation (4) yields $T\lesssim4\times10^5$–1.6×10^6 K. Thus the absence of significant flow velocities at coronal temperatures is a natural consequence of momentum conservation.

So far the cause of mass flow has not been considered. A complete description of the flow requires consideration of the energy equation[9,16-18]; in the present model, spatial asymmetry of the coronal energy source powers the flow. Figure 1 shows temperature profiles for peak temperatures of 10^5, 3×10^5 and 10^6 K, with a flow speed of 5 km s^{-1} at 10^5 K, computed for the simplest case of a localized 'point' energy source. The heating asymmetry is immediately apparent. Indeed, extreme heating asymmetry is required to drive flows of the observed magnitude. The flow originates as follows[9]. Energy is transported most readily (by thermal conduction) towards the closer footpoint, where the excess heat flux 'boils off' chromospheric material. The conductive flux into the downflowing leg of the loop is weaker, allowing the gas to cool as it flows towards the distant footpoint, where it condenses back into the chromosphere. Note that the coronal heat source is only ~10% of the loop length above the chromosphere in the upflowing leg. Larger flow speeds require even greater asymmetries[18].

Turning briefly to the question of gravity and area non-uniformity, we find that these can significantly alter the flow pattern, but in opposite senses. Gravity causes the gas density to decrease with increasing height, thus the velocity of upflowing plasma, $v=q/\rho$, tends to increase more quickly, enhancing the influence of dynamic pressure and reducing the maximum temperature (equation (3)) still further. Fast flows may therefore be constrained not only to cool loops, but also to low-lying loops. If the loop area A increases with height, the velocity, $v=q/A\rho$, rises less quickly, so that the constraints on loop temperature and height are somewhat relaxed. However, physically realistic area variations seem unlikely to produce a major effect[18].

Thus we conclude that all features of the observed flows follow from the analysis presented here. Specifically, steady flows that exhibit substantial transition region velocities with a predominance of redshifted emission, and which disappear at coronal temperatures, are naturally explained. The theory will be strengthened if spatially resolved observations can confirm the predicted asymmetry in loop structure associated with fast flows.

This research was partially supported by NSF grant ATM85-96006.

Poly(styrene peroxide): an auto-combustible polymer fuel

K. Kishore & T. Mukundan

Department of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore 560 012, India

Commonly, polymers exhibit extremely slow, candle-like burning, although oxidizers can increase the rate of combustion, as in solid propellants. Polymer degradation occurs before combustion, and being endothermic, demands a continuous supply of energy. However, if a polymer can degrade exothermically, it can sustain degradation and automatically increase the rate of combustion (autopyrolysis). Poly(styrene peroxide), PSP, which degrades exothermically[1] is such an exceptional and rare example. We explored the possibility of autopyrolytic behaviour in PSP. Interestingly, it was observed that, once initiated, PSP not only sustains its own degradation, but also supports a flame in air, with a burning rate comparable to that of solid propellants. This makes PSP an ideal candidate for a special fuel, such a fast-burning autopyrolytic polymer being hitherto unknown. Here, in the first reported study on the combustion of a polymeric peroxide, we examine some salient features of the combustion of this unique auto-combustible polymer and potential fuel, and show that the combustion is controlled by polymer degradation.

PSP was prepared and purified from styrene and oxygen as reported by Miller and Mayo[2]. It was characterized by ^1H and ^{13}C NMR, IR and Raman spectroscopy. The PSP samples containing additives (nitrobenzene and *p*-toluidine) were prepared by dissolving PSP and the additive (one mole for every 20 polymer repeat units) in acetone, followed by removal of solvent. The polymer was filled free of air bubbles in glass tubes 8 mm in diameter with cotton support. The sample was ignited using a nichrome wire, and the linear burning rate was measured. The burning rates (the average of five repititions) were closely reproducible (within 1% error). Temperature profile measurements were carried out using a chromel-alumel thermocouple (0.127 mm in diameter) inserted into holes drilled into the polymer sample so that the thermocouple bead was well inside. The thermocouple output was fed to a Philips (PM 3234, 0-10 MHz) double beam cathode ray storage oscilloscope, maintained at a sensitivity of 5.8 mV cm^{-1}. The sample tubes were insulated with plaster of paris to minimize lateral heat losses. The degradation peak temperatures of PSP with and without additives were obtained on a DuPont 990 differential scanning calorimeter at a heating rate of 20 °C per min with a sample weight of ~2 mg. The temperature axis was calibrated using benzoic acid.

Pyrolysis gas chromatography studies of the same samples were carried out on a Shimadzu GC-4C gas chromatograph, with attached PYR-1A pyrolyser using a dioctyl phthalate coated on a chromosorb column. Nitrogen (35 ml min^{-1}) was used as carrier gas. The samples were pyrolysed at 200 °C, and chromatographed on the column heated at 5 °C min^{-1}, from 50-125 °C. The products were identified by comparison with retention times of pure compounds. The three sample weights varied and hence the aldehyde peak intensities are not the same.

Table 1 Degradation peak temperatures and burning rates of PSP with and without additives

Additives (5 mole % per repeat unit of PSP)	DSC peak temperature (°C)	Linear burning rate (mm s^{-1})
Nil	149.0±0.2	2.00±0.03
p-Toluidine	141.8±0.2	2.47±0.03
Nitrobenzene	158.4±0.2	0.162±0.001

DSC, differential scanning calorimetry

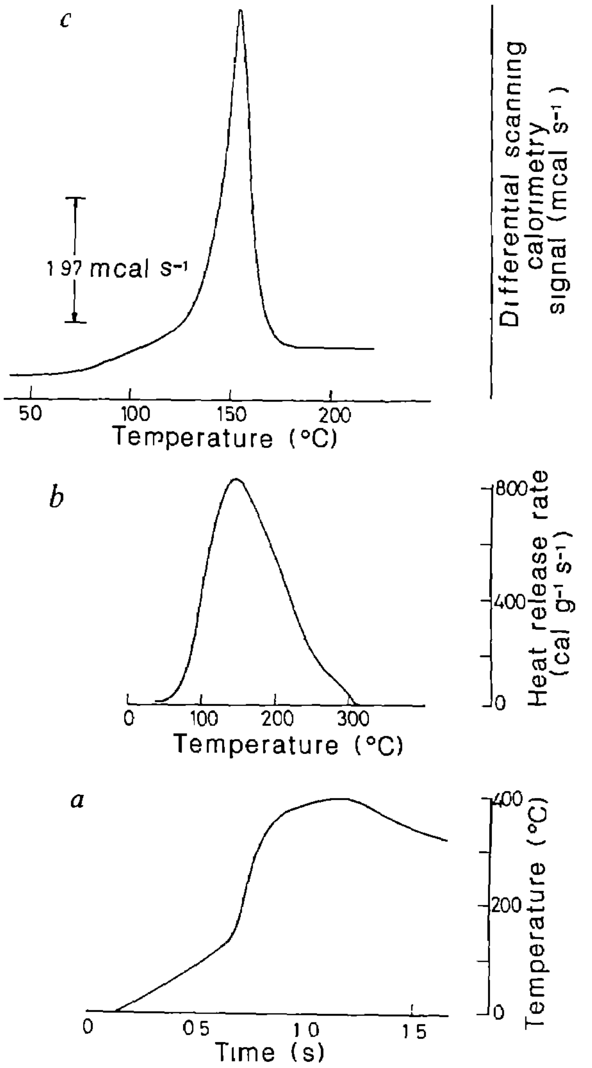

Fig. 1 Thermal profile of poly(styrene peroxide). *a*, Time-temperature trace during combustion, *b*, computer generated, rate of heat release against time plot, *c*, differential scanning calorimetry trace of degradation, heating rate = 20 °C min^{-1}, sample weight ~2 mg

PSP degrades via a radical chain scission mechanism[3] giving benzaldehyde and formaldehyde as major products. A recent pyrolysis gas chromatography study (in the pyrolysis range 120-430 °C) confirms the formation of these two products and accounts for more than 90% of the total degradation products[4]. The remaining products might be formed due to the radical and ionic disproportionation mechanism as proposed by Mayo and Miller[3].

A typical temperature profile (time-temperature trace) is shown in Fig. 1*a*. Heat release rate (dq/dt) at any instant can be calculated from the equation,

$$\frac{dq}{dt} = C_p \frac{T_2 - T_1}{t_2 - t_1}$$

T_2 and T_1 being the temperatures at time t_2 and t_1 respectively, and C_p the average heat capacity of PSP. The profile data were fed into the computer to obtain a plot of dq/dt against T. The temperature dependence of C_p, measured by differential scanning calorimetry was obtained using a computer fit ($C_p = 0.001236T + 0.3541$). The value of C_p above 90 °C, when PSP starts to degrade during combustion, was determined by extrapolation of this fit. The plot of dq/dt against T is given in Fig. 1*b*. A typical calorimetric trace (of PSP degradation) that relates the rate of heat flow (dq/dt) to time/temperature, is shown in

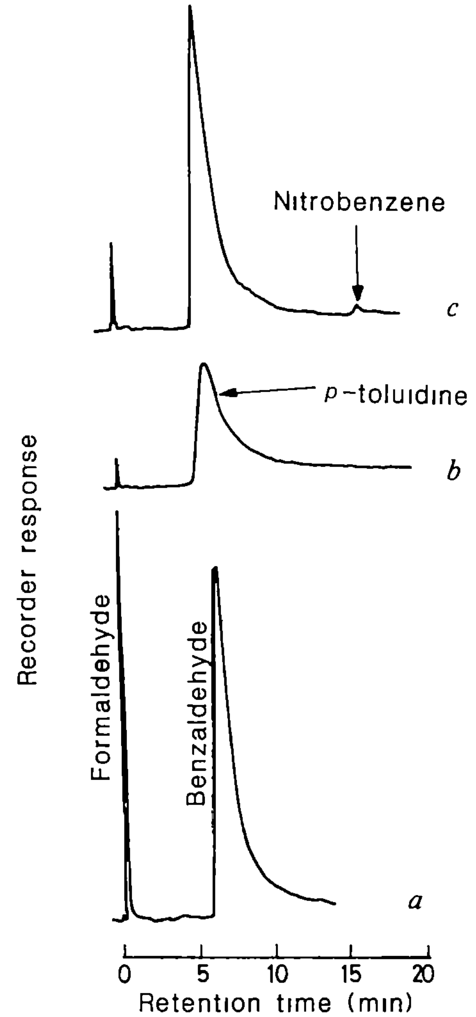

Fig 2 Pyrograms of PSP samples *a*, PSP, *b*, PSP+*p*-toluidine (merges with benzaldehyde) and *c*, PSP+nitrobenzene

Fig 1*c* Note that the solid-gas interface temperatures (surface temperatures) where PSP degradation occurs coincides in the two cases shown in Fig 2*b*, *c*

The profile experiment was used to determine the heat of degradation of PSP during its combustion PSP initially at ambient temperature degrades and the gaseous products are heated to a maximum temperature before entering the flame at the mouth of the tube The enthalpy change for PSP going from ambient to maximum gas temperature is $\Delta H = C_p(T_2 - T_1)$, T_2 and T_1 being the maximum gas temperature (400 °C) in the profile (Fig 1*a*) and ambient temperature (25 °C) respectively, an average value of $C_p = 0\ 54$ cal mol^{-1} at the surface temperature, 150 °C, was used Corrections for vaporization of benzaldehyde and formaldehyde[1] were made to the above value of ΔH and the heat of degradation of PSP from the combustion experiment thus obtained was 45 0 kcal mol^{-1} Considering the heat losses that occur during the combustion experiment this value is in reasonable agreement with the experimental value reported earlier[1] Comparing the heat of degradation value obtained from the profile experiment and those from differential scanning calorimetry (50±1 kcal mol^{-1}) and thermochemical calculations[1] (52±1 5 kcal mol^{-1}) suggests that combustion of PSP occurs as a consequence of its degradation, otherwise heat released before combustion should differ from the heat of degradation obtained by scanning calorimetry This conclusion is supported by the following observations (1) During combustion, the flame remains at the mouth of the tube, while the surface at which degradation occurs recedes, that is, the flame persists as a result of the combustion of PSP degradation products, (2) under controlled conditions PSP degrades without a flame, the regression rate being equal to the burning rate

A corroboration of this inference was sought with the help of two additives Thermograms were recorded to obtain degradation peak temperatures with and without these additives, the linear burning rates were also measured (Table 1) It can be seen that the additives bring about similar changes in combustion and degradation, *p*-toluidine accelerates both, while nitrobenzene decelerates both

Pyrolysis gas chromatography of the PSP samples containing additives was carried out to investigate the effect on PSP degradation (Fig 2) No new degradation products were formed in the presence of the additives and the overall composition of the degradation products remained the same In the case of the PSP-nitrobenzene sample, nitrobenzene has a longer retention time (Fig 2*c*), while for the PSP-*p*-toluidine case the *p*-toluidine merges with the benzaldehyde peak (Fig 2*b*) These results suggest that the additives only affect the rate of reaction rather than the mechanism of PSP degradation A detailed study of this aspect, which unavoidably falls beyond the realm of this preliminary report, would prove vital in regulating the rate of combustion for potential use of the polymer as a fuel However, the present investigation describes the unusual phenomena of autopyrolysis and autocombustion of an unadulterated polymer and unambiguously proves that its combustion is primarily controlled by degradation

We thank Mr P A Joy and Mr M Jayamurthy for their help in computations

Submarine hydrothermal vents were first unequivocally detected by measurement of ^{3}He/^{4}He ratio anomalies coupled with deviations from ambient T–S relationships on the Galapagos spreading centre[1,2]. Since then the existence of hydrothermal vents along the entire length of the East Pacific Rise has been demonstrated by shipboard observations of ^{3}He, methane, and manganese in the effluent plumes[3–5]. We have extended our studies of vent fields at mid-ocean-ridge spreading centres to search for effluent plumes in back-arc basins, which are also thought to be active regions of seafloor spreading where new oceanic crust is formed[6], and thus where rifting and fissuring along the axis of extension should provide similar opportunities for the downward penetration of sea water and the development of active hydrothermal systems. We have detected large plumes of methane-enriched water in the Mariana Trough back-arc basin[7] and also in the summit crater of Loihi Seamount[7] at the present site of the Hawaiian hotspot, thus establishing the widespread existence of 'off-ridge' hydrothermal vents in the ocean. However, although the Loihi vents produce plumes enriched in both ^{3}He and methane[7], we find that, surprisingly, the Mariana vents are enriched in methane without a corresponding enrichment in ^{3}He This is the first time such a 'decoupling' of these two effluent plume tracers has been observed.

---

‡ Present addresses Scripps Institution of Oceanography, La Jolla, California 92093, USA (Y H), Department of Oceanography, Seoul National University, Seoul 151, Korea (K -R K)

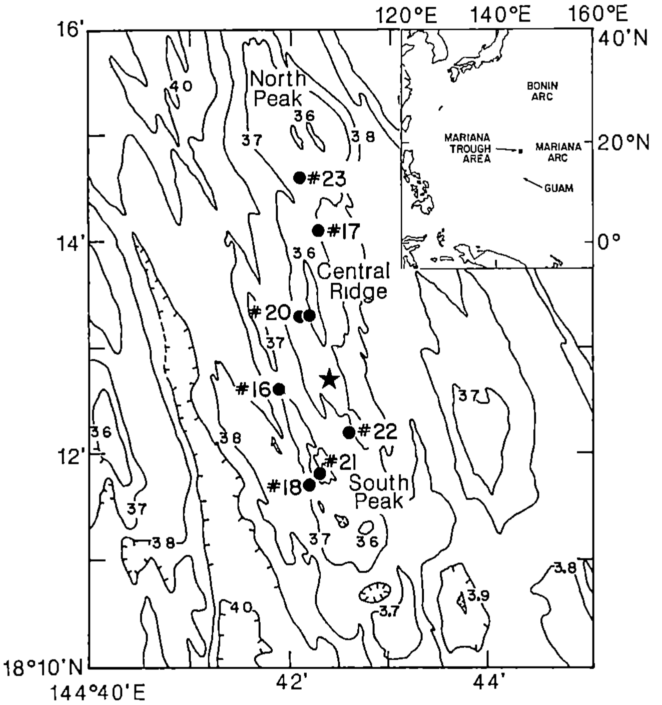

Fig. 1 Cepheus station locations in the Mariana Trough The stations lie between two large volcanic peaks four miles apart, along a ridge of fresh lavas from fissure eruptions This section is a high spot in the Mariana Trough and was chosen for investigation because the axis is accessible for study by the submersible Alvin (depth < 4 km) The star on Central Ridge marks the site of a 0 02 °C temperature anomaly observed with Deep Tow by P Lonsdale, who made this map A CTD towed on the Cepheus expedition also detected a 'true' hydrothermal plume spike in the vicinity of station 20, with amplitude 0 01 °C Depth contours in km

Our search for off-ridge hydrothermal vents was carried out in a region of the axial rift valley between 18°11′ N to 18′15′ N, at the suggestion of P Lonsdale, who had previously (with the Deep Tow CTD (conductivity, temperature, depth) observed small temperature spikes in the water column that were 'real' plumes in the sense that corresponding decreases in salinity were lacking[1] The shipboard work was done on the Japanese vessel *Hakuho Maru* on the Cepheus expedition[8], in the area shown in Fig 1, which was mapped by Lonsdale Seven hydrographic stations were occupied along the axial volcanic ridge, a methane plume was observed in all cases although complete profiles through the plume were obtained at only four of the stations

Figure 2 shows the Mariana methane plume in section from south to north along the ridge crest The core concentration of methane is 74×10^{-6} cm^3 kg^{-1} at a depth of 2950–3000 m, increasing slightly toward the northern peak The plume rises 600–700 m above the bottom before entraining enough ambient water to reach density equilibrium and spread horizontally along the 3000 m isopycnal (1041 428 kg m^{-3} at 2957 m) This 'upper' plume is distinctly separated from the lower more discontinuous plume ~200 m above the sea floor, and it is obviously generated by more active vents We suppose that the 'upper' plume is a '21° N'-type plume generated by the so-called 'black smokers', which vent high-temperature water from chimneys above the sea floor, whereas the lower and much more dilute plumes probably represent the low-temperature 'Galapagos-type' effluent from a cooled subsurface reservoir These lower plumes are discontinuous in section because of the offset of the axial ridge at 18°12 5′ N (Fig 1) We have observed[9] similar sets of near-bottom and 'upper' plumes on the East Pacific Rise at 20° S, where the plumes are clearly associated with vents as shown by Angus photographs of the vent fauna However, the East Pacific Rise plumes generally rise only some 300 m above the ridge crest before spreading horizontally[9,10], much less than the height observed here As we observed that the potential density gradients are quite similar both in the Mariana plume and at several localities on the East Pacific Rise, it is possible that the much greater rise height of the Mariana plume is due to higher effluent temperatures, perhaps above 400 °C, from very large 'black smokers'

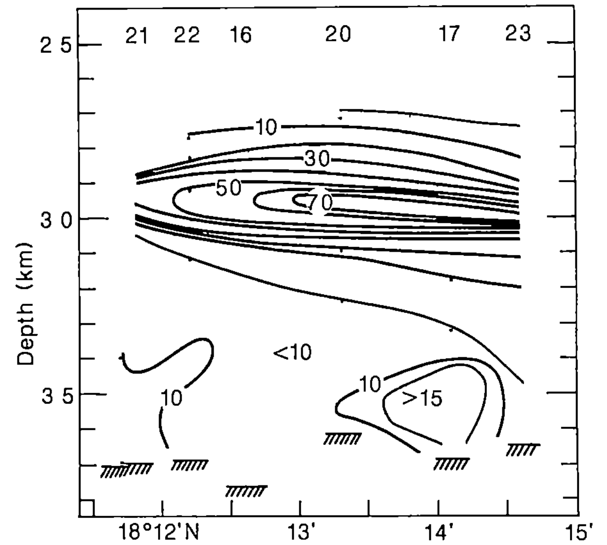

Fig 2 Structure of the methane plumes along the Mariana Trough spreading axis Station numbers are along the top, methane contours are in 10^{-6} cm^3 (STP) methane per kg sea water Bottom depths at the stations are indicated by cross-hatched bars

Table 1 shows the methane and helium data at station 23, the only station for which a helium profile was obtained The ^{3}He/^{4}He ratio anomalies are tabulated as $\delta\,^3$He values (in per cent), that is, the percentage enrichments relative to the atmospheric ratio The saturation anomalies relative to atmospheric solubilities[11] are also listed for both He isotopes and for neon, and finally the absolute He isotope concentrations are tabulated for each isotope

Figure 3 shows the $\delta\,^3$He profile superimposed on the methane plumes from stations 20 and 23, and it is seen that the very large and sharp methane maximum is not reflected in the ^{3}He profile A close reading of Table 1 shows that there is probably a very slight maximum in $\delta\,^3$He between 3,000 and 3,145 m, correlated with a similar slight maximum in the solubility anomalies and absolute concentrations of the He isotopes The solubility anomalies and absolute concentrations of ^{3}He indicate that there may be a small maximum at 3,000 m, amounting to no more than 0 8% Comparison with the methane peak indicates that the methane/^{3}He ratio in the added volatiles must be $> 100 \times 10^{-6}$, which is much greater than the $\sim 3 \times 10^{-6}$ observed at East Pacific Rise vent fields[5,12] We also find that, in detail, the ^{3}He and ^{4}He concentrations are well correlated ($r = 0$ 87), with a slope corresponding to a mixture of a He component with a ^{3}He/^{4}He ratio of only 3 2 (± 0 7) times atmospheric, rather than a ratio of 8 as observed on mid-ocean ridges This indicates that there is a significant radiogenic He component in the Mariana vents in addition to the large methane enrichment relative to He These data as a whole thus suggest that some effects we have not encountered on the East Pacific Rise have significantly influenced the volatile compositions in the Mariana vents

A methane profile was also measured in the so-called 'Mounds' area west of the axis of the Mariana Trough at 18°01′ N, 144°18′ E, an area of high heat flow thought to be a site of hydrothermal activity[13] Samples were collected at 12 depths from 2,930 to 3,515 m, above the bottom depth of 3,534 m The observed methane concentrations had a mean of (4 3 ± 0 4) × 10^{-6} cm^3 kg^{-1}, which is identical to the ambient methane back-

Table 1 Methane, ^{3}He, ^{4}He, Ne and potential temperature (T_{pot}) measurements for Cepheus expedition station 23

Depth (m)	T_{pot} (°C)	Methane (10^{-6} cm^3 kg^{-1})	δ^3He (%)	ΔNe (%)	Δ^4He (%)	Δ^3He (%)	^{4}He (10^{-6} cm^3 kg^{-1})	^{3}He (10^{-12} cm^3 kg^{-1})

Seawater samples were collected in 23-litre Niskin hydrographic bottles, with the use of a pinger to measure distance above the sea floor Samples of 40 ml (He) and 1 liter (methane) were drawn in tandem in copper tubing and Pyrex cylinders The He samples were sealed with refrigeration clamps and were extracted at Scripps Institution of Oceanography and analysed for ^{3}He/^{4}He ratios and He and Ne concentrations (by isotope dilution) as described by Lupton and Craig[10] Methane measurements were made on board with the Shimadzu FID (flame ionization detection) gas chromatograph and vacuum extraction system described by Kim[9]

The salinity at 2,705 m is 34 657‰, below this depth the salinity is (34 663 ± 0 002)‰, that is, constant to within the precision of the measurements[8] δ^3He $= (R/R_A - 1)\times 100$, where $R = {}^3$He/^{4}He in the sample and R_A refers to atmospheric ^{3}He/^{4}He ratio ($=1\ 40\times 10^{-6}$) The Δ values for Ne, ^{3}He and ^{4}He are the saturation anomalies relative to atmospheric solubility at the potential temperature of the sample[11] Slight corrections for air leakage into the copper samplers have been made to the He results for five of the samples in which excess Ne was observed (ΔNe values in parentheses) ΔNe values between 3 0 and 3 3% are normally distributed owing to random errors, and the mean of these values, 3 17%, is taken as the actual Ne solubility anomaly For the five samples with ΔNe > 3 3%, the ΔHe values are reduced by subtracting 1 276 (the solubility coefficient ratio) times the Ne solubility deviation from the mean The recalculated anomalies in ^{3}He and ^{4}He ratios and solubilities, and the absolute concentrations of ^{3}He and ^{4}He, are tabulated for these five samples The precision of the ^{4}He concentration data is ~0 3% The precision of the δ^3He measurements is about 0 7%, so that the corrections for air leakage for these data are not significant except for a 0 6% correction for the 2,901 m sample However, these corrections were made very carefully because the lack of a sharp maximum in the isotope ratios or absolute concentrations made us look very closely at the data

ground in the Mariana Trough samples, (3 9 ± 0 6) × 10^{-6} cm^3 kg^{-1}, obtained by averaging 23 samples with minimum methane concentrations in the same depth range at stations 16–23 on the axis of the trough Thus if hydrothermal activity is present at the 'Mounds' site, it is not intense enough to make observable methane plumes and it must be extremely diffuse

In conclusion, we have observed a large hydrothermal methane plume rising 700–800 m above the sea floor and extending several miles along the axial region of the Mariana Trough The discovery of this plume extends the source of submarine hydrothermal vents to the extensional region of back-arc basins, which implies that there is much more hydrothermal activity in the ocean than previously thought However, the lack of a strong helium signal associated with the methane plume, and the relatively low ^{3}He/^{4}He ratio in the added He, indicate that significant differences in chemistry are present in the mantle sources and hydrothermal water-rock interaction processes in the marginal basins of the oceans Thus we look to the forthcoming Alvin investigations in these regions to increase our understanding of these effects

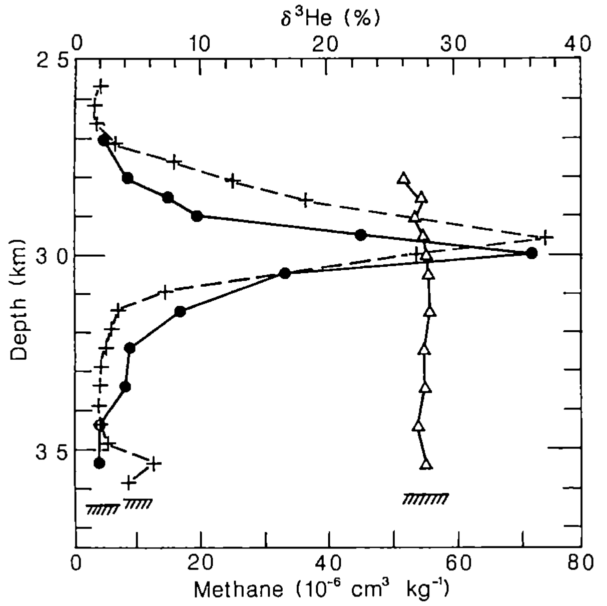

Fig 3 Methane plumes at stations 20 (dashes) and 23 (solid), compared with the δ^3He isotopic ratio anomaly relative to atmospheric helium at station 23 (triangles)

We thank H Tsubota, M Fukazawa, T Gamo, H Inoguchi, H Morinaga and the officers and crew of the vessel for assistance aboard the *Hakuho Maru* We are grateful to Peter Lonsdale for his detailed map and discussions of the Mariana Trough area, and to R L Chase for helpful comments The work at La Jolla was supported by the NSF Division of Ocean Sciences

Note added in proof Since this paper was submitted we have extended our observations of back-arc hydrothermal methane plumes to the central spreading axis of the Lau Basin in the southwest Pacific[14] Hawkins and Helu[15] have dredged sulphides of probable hydrothermal origin from this basin, and Both *et al*[16] have photographed hydrothermal chimneys and vent fauna on the spreading axis of the Manus Basin, where we subsequently observed large methane plumes (Papatua expedition, 1986)

The Kerguelen Plateau in the southern Indian Ocean stands 2–4 km above the adjacent sea floor and is ~2,500 km long (Fig 1)[1,2]. Seasat provided a unique data set for deriving the free-air gravity field of the region (Fig. 2)[3–5]. Here we report the results of a new analysis of the plateau province's structure employing both Seasat and newly-acquired multichannel seismic (MCS) data[6,7] for ground truth. The northern sector is characterized by volcanism and a sedimentary basin; the southern sector by a broad anticlinal arch, major faulting, and a sedimentary basin; and the eastern sector by an abyssal basin (Labuan) and bounding ridge (William's). The three sectors argue for a more complex tectonic evolution of the feature than has been previously proposed.

Seasat's radar altimeter, pulsing 1,000 times per second, allowed the determination of the average distance between the satellite and several square kilometres of the sea surface directly beneath it One-second averages of the distances, each representing ~8 km of ground track, provided continuous profiles of sea surface topography to a precision of 5–10 cm The ocean surface closely coincides with the geoid, the gravitational equipotential surface reflecting the mass distribution within the Earth Variations in gravitational acceleration computed directly from the geoid surface[4] result in gravity anomaly estimates accurate to 5 mGal with a spatial resolution of 25–50 km Although less accurate than shipboard gravity measurements at spatial scales <100 km, Seasat's uniform track coverage (<5 to several tens of kilometres spacing)[5] permits comprehensive mapping of the gravity field with consistent accuracy (Fig 2), whereas shipboard measurements are sparse in the plateau region (Fig 1) and are inadequate for regional analyses Caution must be exercised in viewing the gravity map south of ~60 °S sea ice increased altimeter noise by an order of magnitude and thus reduced precision, features of dimensions less than several tens of kilometres may be artefacts of the sea-surface gridding procedure or represent measurement noise, and features lineated in the satellite track directions may be artificial, resulting from uncertainties in correlating measurements along adjacent profiles

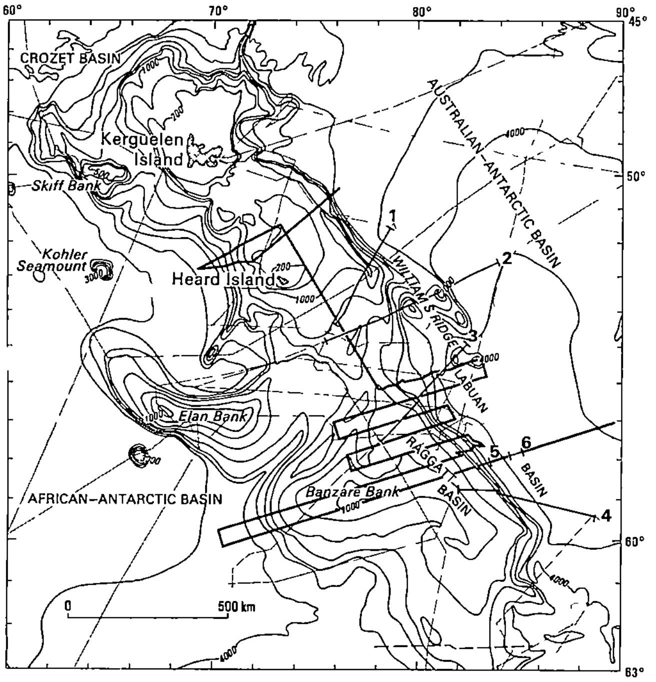

Fig 1 Bathymetry of the Kerguelen Plateau based on shipboard echo-sounding and the Seasat-derived free air gravity field, contour interval is 500 m Seismic control is indicated as follows thick solid lines, 48-channel seismic, dashed lines, digital single-channel seismic, thin solid lines, analogue single-channel seismic All lines have gravity, magnetics, and bathymetry Numbered segments (1–6) indicate profiles displayed in Fig 4

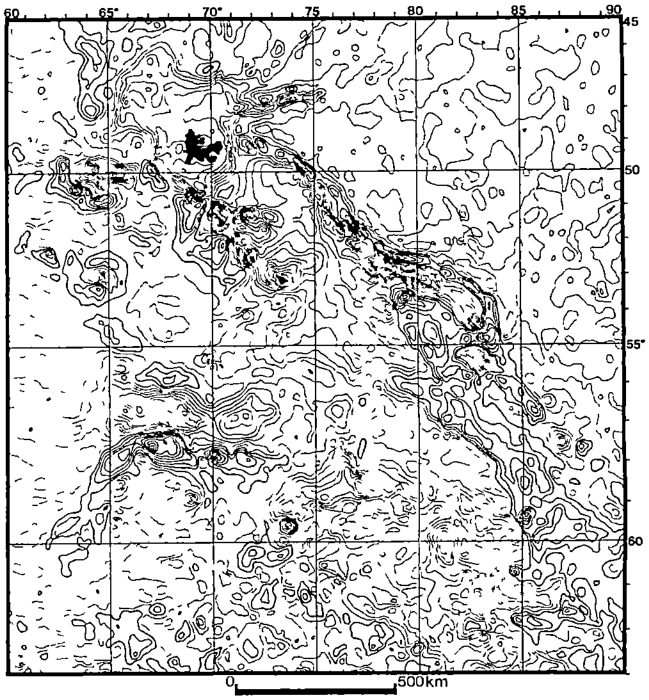

Fig. 2 Seasat-derived free-air gravity field of the Kerguelen Plateau The contour interval is 8 mGal, and the 0 mGal contour is drawn in a heavy black line Kerguelen and Heard islands are in solid black Compare with bathymetry in Fig 1

In 1985, the R/V *Rig Seismic* acquired the first multichannel seismic data over the southern and eastern sectors of the Kerguelen Plateau province[6,7] Two airguns (500 cubic inches) comprised the sound source, and the 1,200-m streamer was configured for 48 channels, allowing 12-fold coverage The record length was 7 s, with a 2 ms sampling rate The data are high quality and reveal far more structural detail than do the older single channel seismic data[1]

Figure 3 summarizes the new structural interpretation of the Kerguelen Plateau province The northern sector includes the province's only islands, composed of volcanics and volcanics/intrusives[8], and offshore comprises a major sedimentary basin[9] as well as numerous smaller basins separated by igneous intrusions or basement horsts[1,2,6,7,9–11] A large positive gravity anomaly coincides with the north-west end of the plateau, defining an apparent structural entity we term the 'Kerguelen massif' The massif, sub-rectangular except for a narrow ridge extending east-northeast from the northeastern margin, includes the Kerguelen Islands in the south and small sedimentary basins in the north and north-east South-southeast of the Kerguelen massif, and separated from it by a transverse gravity trough, is an amalgamation of generally positive gravity anomalies extending as far as Heard Island The largest of the positive anomalies

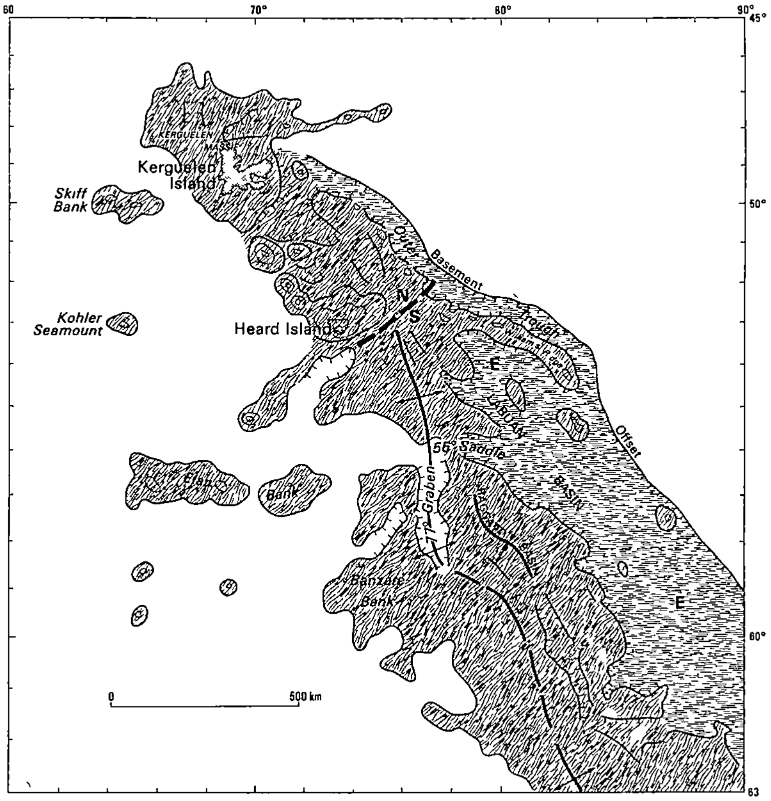

Fig 3 Morphotectonic map of the Kerguelen Plateau province based on combined analysis of Seasat-derived gravity and seismic reflection data Diagonal stippling indicates elevated areas, horizontal stippling indicates deep basins Scarp symbols indicate moderate to steep gravity gradients, in some cases coinciding with normal faults N/S, boundary between northern and southern sectors, E, eastern sector Anticline symbol indicates axis of broad arch of southern sector and syncline symbol indicates axis of Raggatt sedimentary basin The names William's Ridge and Labuan Basin have been formally proposed to the Australian Hydrographer for these newly-defined features

extends for some tens of kilometres north-east and north-west from Heard, and probably demarcates the volcanic pedestal of the island Other discrete, strong sub-circular positive anomalies extend north-west from Heard Island in a rectilinear chain; the major sedimentary basin[9] lies north-east of the chain A series of more subdued positive anomalies extends north-west along the north-east margin of the plateau Where MCS data are available, we observe that the positive anomalies coincide with volcanic pedestals, horsts, or peaks of intrusive rock[6,7] Intervening irregularly-shaped negative anomalies coincide with small, well-developed sedimentary basins. The positive anomalies along the north-east margin, although not obviously horsts, lie along trend from horst blocks of the southern and eastern sectors

The boundary between the northern and southern sectors lies on a transverse line immediately south-east of Heard Island, and is marked by a distinct change in gravity signature and structural style The bulk of the southern plateau is characterized by a more subdued gravity field and a simpler structural regime than the northern sector The southern sector comprises a single broad anticlinal arch, disturbed by normal faults, but, unlike the northern sector, not obviously intruded by igneous rocks Fault motion appears to have occurred over a long time interval[6,7] In places faulting, non-deposition and/or current erosion have resulted in exposure of igneous basement on the sea floor From the boundary with the northern sector at ~53 °S southwards to a prominent saddle at ~56 °S, the anticlinal arch plunges gently south-southeast, it is bounded to the north-east by a series of horsts and grabens[9] but the south-west flank is a simple, gentle slope. Coincident with the saddle at 56 °S, the arch may be cut by a transverse graben South-southeast of the saddle the arch rises and reaches maximum development at ~58 °S, where it is ~500 km across and rises to ~700 m depth Banzare Bank forms the southwest flank of the arch at these latitudes The axis of the arch is marked by a graben which trends almost north–south, the 77° Graben[1], half-grabens on the flanks face towards the central axis The Raggatt Basin (Fig 3), and seismic horizons within it, extend over hundreds of kilometres, and sediment thickness in places is >2 s two-way time[6,7] (twt)

The two major morphotectonic components of the eastern sector are a broad, deep morphological basin (Labuan) and a bounding ridge (William's) These features are characterized by prominent gravity gradients and, in the case of the Labuan Basin, by the broadest negative gravity anomalies of the entire Kerguelen Plateau province Figure 4*a* illustrates the apparent continuity of structure from the horsts and grabens of the north-east margin of the northern and southern sectors into the basins and ridges of the eastern sector Figure 4*b* displays active boundary faults between the eastern and southern plateau sectors The faults coincide with a sharp gravity, gradient, and earthquakes have occurred along trend <35 km north of the seismic line[12,13] The deep basement of the Labuan Basin extends to the southeasternmost extent of the seismic data (~62 °S), and its associated negative gravity signature to the limits of the Seasat-derived gravity data at 63 °S The Labuan Basin seems to extend farther to the Antarctic margin Figure 4*c* shows basement in the basin, it is faulted, averages 7–8 s (twt) in depth, reaches maximum depths of ≥8 s (twt), and has a sediment cover of 0- ≥2 s (twt) thickness Discrete sub-circular strong positive gravity anomalies at 55 5 °S and 57 5 °S are probably seamounts William's Ridge is ~500 km long Profile 2 in Fig 4*a* is the only complete seismic transect of the feature The ridge stands ~1,500 m above the adjacent ocean floor, is ~100 km across, and appears to consist of a series of horst blocks North-east of Labuan Basin and William's Ridge is a sharp gravity gradient which corresponds to changes in basement depth, morphology, and structure[1,6,7] North of ~55 °S the transition observed on seismic data is abrupt[1], and to the south more gradual[6,7] This basement offset (Fig 3) marks the boundary of the eastern sector of the Kerguelen Plateau province with the Tertiary oceanic crust dated by marine magnetic anomalies[2]

The recognition of an eastern sector of the Kerguelen Plateau province and marked differences in the structure of the three plateau sectors implies a more complex evolution of the feature than has been proposed[1,14-16] Specifically, there is a need to review previous fits of the Kerguelen Plateau province and Broken Ridge Previous reconstructions[1,14,15] have employed parameters derived from the separation of Australia and

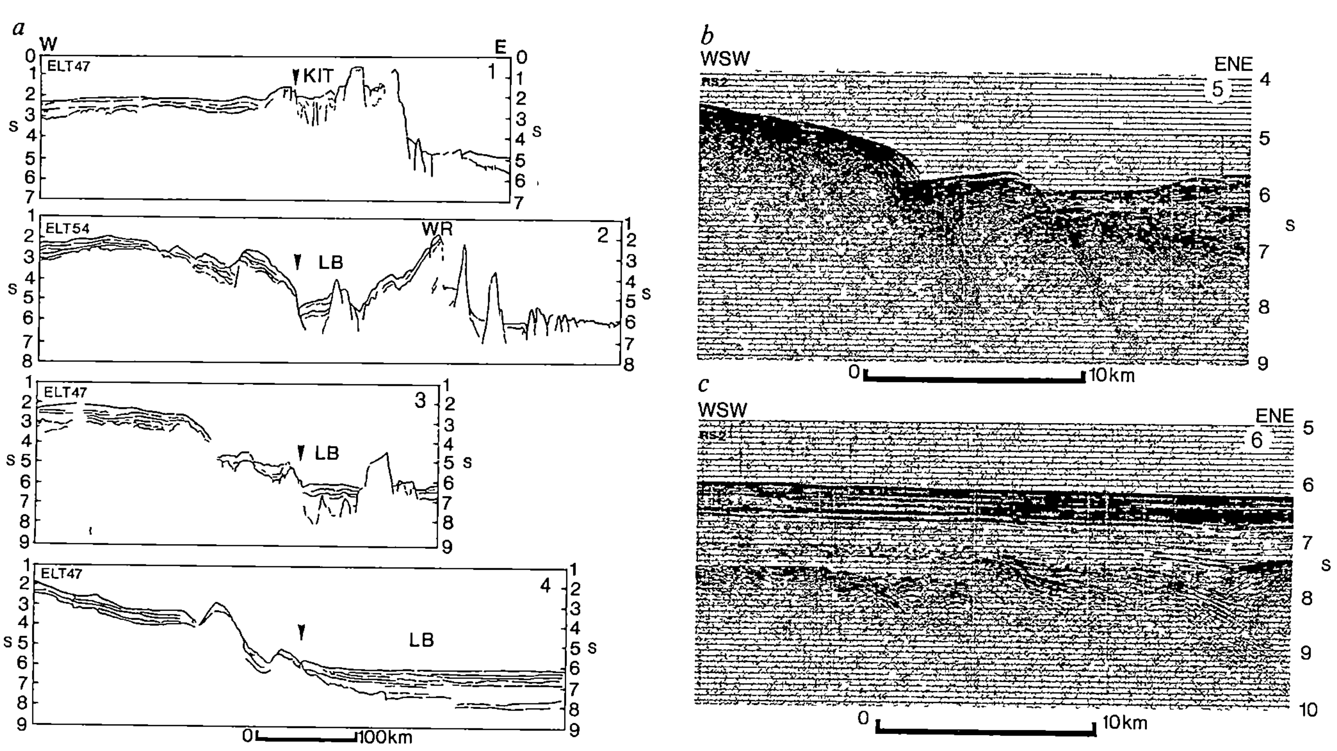

Fig 4 Seismic data documenting the eastern sector of the Kerguelen Plateau province ELT, line drawings of *Eltanin* single-channel seismic data, RS, *Rig Seismic* MCS data Profiles are numbered in upper right hand corner, see Fig 1 *a*, Sequence of line drawings across the north-east margin of the Kerguelen Plateau province Grabens of the Kerguelen Island Trough (KIT)[1] form an apparent rift zone high on the plateau (1), descend (2) into the Labuan Basin (LB, 3), and persist far to the south (4) William's Ridge (WR), previously mapped as an isolated seamount on pre-Seasat bathymetric maps[1,2], is on the north-east end of profile 2, which is the only existing complete transect of the feature The drawings are aligned (black arrows) along the western flank of the Kerguelen Island Trough and Labuan Basin *b*, Seismic line showing detail of major faulting marking the boundary between the southern and eastern plateau sectors Earthquakes in 1973 and 1981 occurred along trend <35 km to the north[13] *c*, Seismic line showing basement character of Labuan Basin

Antarctica, we suggest a new reconstruction employing Seasat-derived fracture zone azimuths between the Kerguelen Plateau and Broken Ridge Dating of the eastern sector and of the Diamantina Zone, presumed conjugates[7], is vital to any tectonic reconstruction for the region

The relationship between the Kerguelen Plateau and hotspot volcanism needs further attention Flexure studies and/or sampling are needed to test if certain apparently compensated components of Kerguelen Plateau province—Elan Bank, Skiff Bank and Kohler seamount—are volcanic edifices whose origins may be unrelated to those of the generally uncompensated main northern, southern, and eastern plateau sectors The rectilinear chain of seamounts between Kerguelen and Heard islands suggests a slow north-west movement of the Antarctic plate in the interval 39–10 Myr, contradicting previously determined Antarctic plate motions[1,17,18] Resolution of the conflicting evidence on absolute motion of the Antarctic plate awaits further sampling and age dating of the volcanic rocks on the plateau The southern plateau sector, in having far greater relief, active major faulting, and no evidence of Neogene volcanism, differs from typical hotspot swells[19] Gaussberg volcano on Antarctica, although chemically distinct from Kerguelen Plateau volcanics[20], lies along the trend of the plateau—is it part of the plateau province? Although further geophysical studies may provide clues, Ocean Drilling Program operations on the Kerguelen Plateau planned for 1987-88 have the most potential for resolving questions of the feature's origin and evolution

We thank the master, crew and the scientific staff of the R/V *Rig Seismic* for their roles in acquiring the multichannel seismic data C Brenner, M Weigel and the BMR Drawing Office provided technical assistance We thank S Cande, J Colwell, P Hill, M Munschy, C Pigram, D Ramsay, R Schlich, J Sclater, H Stagg and B Willcox, for critically reading the manuscript M F C and H L D publish with the permission of the Director, Bureau of Mineral Resources, Lamont-Doherty contribution 4057

Oxygen isotopes and sea level

J. Chappell* & N. J. Shackleton†

* Biogeography and Geomorphology, Research School of Pacific Studies, Australian National University, Canberra, Australia
† Godwin Laboratory for Quaternary Research, University of Cambridge, Free School Lane, Cambridge CB2 3RS, UK

From the time that detailed oxygen isotope records derived from foraminifera living in the constant-temperature environment of the abyssal ocean became available, there has been a discrepancy between the ice volume record that these records imply, and that derived from the altitude of dated coral terraces around the world. Here, we re-examine the data and conclude that the temperature of the abyssal ocean has been an actively varying component of the climate system.

Oxygen isotope ratios in foraminifera from deep-sea sediments have been used as indicators of past climate following Emiliani's pioneering work[1] $\delta^{18}O$ in foraminifera varies with $\delta^{18}O$ in the water from which their carbonate tests are deposited, but differs from the water value by an amount that is temperature dependent[2] The mean $\delta^{18}O$ of the whole ocean varies with the quantity of isotopically light ice stored on the continents so that the record from foraminifera in a particular core is a blend of global (ice volume) and local (temperature) components As the record in planktonic foraminifera may be affected by differences in surface salinity[3] as well as by changing seasonal growth and depth habitat[4], benthic foraminifera have recently been preferred as they provide a less complicated record of global ice volume It has been assumed that the deep ocean, at least in the Pacific, is so cold that its temperature may be regarded as constant as well as spatially uniform

Differences exist between $\delta^{18}O$ records from different cores, even those based on benthic foraminifera Recent studies have isolated systematic differences between good quality benthic records from different regions which have been interpreted as indicating that the deep Atlantic, which at present is ~2 °C warmer than the Pacific, was significantly colder than this during glacial times than at present[5] However, in these studies it was only possible to study inter-oceanic gradients, a change in the average temperature of the whole deep ocean could not be distinguished from a whole-ocean isotopic change

We have made a detailed comparison between a deep Pacific ^{18}O record from core V19-30 (ref 6), and a high-resolution sea-level record from the Huon Peninsula, New Guinea Although neither can be regarded as a perfect monitor of global ice volume, both records must be dominated by a common ice-volume signal In making this comparison, we extend earlier discussions which noted a discrepancy between sea-level records of the past 120 kyr as indicated by raised marine terraces, and by the marine oxygen isotope record[7,8] The record from core V19-30 has been fully documented as has the methodology on which it is based[6] The Huon sea-level record[9] is less well known and its derivation is reviewed to clarify the assumptions involved in comparing it with the ^{18}O record

Sea-level changes over the past 300 kyr have been interpreted from a flight of raised coral terraces along the tectonically rising north-east coast of Huon Peninsula Individual reef terraces were dated using the ^{14}C and $^{230}Th/^{234}U$ methods, which have given good internal consistency within morphological units[10-14] Each reef developed when the rising sea level overtook the rising land, reef crests represent approximately the peaks of each transgression[11,13] Terrace heights increase southeastwards along the coast with increasing uplift rates The morphology and internal structure of each reef indicates the course of sea-level change relative to the rising land, so that sea level relative to stable ocean floor can be extracted for each section if the uplift rate for that section is known

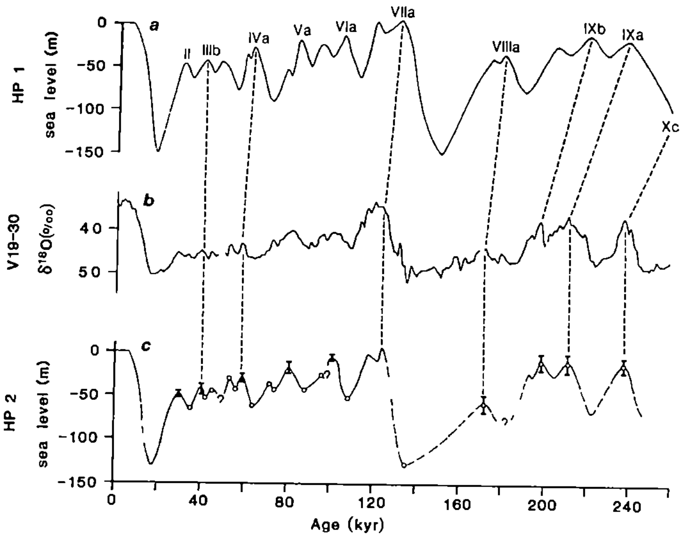

Fig 1 *a*, Detailed sea-level curve for Huon Peninsula from ref 9, with small notches eliminated *b*, ^{18}O record for the past 340 kyr from east equatorial core V19-30, from measurements of benthic *Uvigerina senticosa*, plotted to an orbitally-tuned timescale and smoothed with a three-point running mean *c*, Detailed sea-level curve for Huon Peninsula as recalculated after detailed correlation with the ^{18}O record from core V19-30

We have estimated uplift rates assuming that sea level at ~125 kyr BP was 6 m above the present level[9-12] The spread in radiometric analytical data for this high sea-level event has been interpreted as indicating that this episode may have been prolonged However, stable isotope measurements in both molluscs[15] and corals[16] have confirmed that this interval of high sea level coincided with the rather short substage 5e in the marine oxygen isotope sequence Reef complex VII represents the '125-kyr marker' in the Huon sequence, and is divided into units VIIa and VIIb[9-12,17]

Sea levels associated with other Huon reefs were estimated as follows given the uplift rate U_j based on the elevation of reef VII in section j, sea level $S_{i,j} = H_{i,j} - U_j t_i$ where $H_{i,j}$ is the elevation of the crest of reef i on section j and t_i is the age of reef i Sea levels have been estimated for the reef sequence at seven surveyed sections with uplift rates ranging from 0 9 m kyr^{-1} (north-west end of the flight) to 3 5 m kyr^{-1} (south-east end of the flight)[12] Error estimates for the sea level associated with each reef crest are based on results from all sections, combined with the contribution of dating errors[9] The lower sea levels which intervene between reef crests were estimated in the same way, using the heights of shallow marine and littoral deposits in the Tewai section[9], supported by dates from other sections[13,14]

The detailed sea-level curve for the past 260 kyr derived by this method is shown in Fig 1*a*, modified from the previous version only in that small steps of a few metres amplitude have been smoothed out These steps were interpreted from wave-cut notches throughout the terrace flight, they seem to represent individual seismic events and thus have no global validity[9] The case for regarding Fig 1*a* as a global curve rests on points of agreement with results from elsewhere Sea levels at 105, 83 and 60 kyr agree closely with estimates from Barbados[12] and Timor[13] as well as being supported by dates from the Ryukus[19] and in Vanuatu (New Hebrides)[20] Sea level was estimated in these other areas using the same method, with the reef or terrace of 125 kyr being the reference surface in each case Agreement between sites which are widely separated and which have very different uplift rates supports the global use of the Huon curve However, less support is available for the low points, because

Table 1 Heights, uplift rates and sea-level estimates for Huon Terrace sections

Huon Reef	Age (kyr adjusted)	Tewai	Kanzarua	Blucher	Kwambu	Nama	Sambero	Mean sea level

		−46	−43	−44	−41			−44±2

Height data are from ref. 9 (Tewai) and ref. 12 (other sections). Heights of reef VIIa at all except Tewai and Kwambu are as given for VIIb in ref. 12. Uplift rate is based on VIIa = 12 kyr, sea level at +6 m.

* Estimated, not surveyed, height. All other heights are from theodolite survey.

† Heights of IVb and IIIa based only on Tewai section, as uncertainty exists over whether IIIa surveyed on other sections is equivalent to 53- or 45-kyr isotope points.

the low sea-level deposits are generally buried by those of the subsequent transgression. Low sea-level points are a good test of the global applicability of the curve because isostatic and other factors will probably have their greatest effect between glacial maxima and minima.

The low sea level at 18 kyr corresponding to the last glacial maximum is an important point for comparison with ^{18}O records. Figure 1*a* shows this level at −150 m based mainly on results from northern Australia where lagoonal facies at −135 m (ref. 21), intertidal beach rock at −150 m (ref. 22), and coral below a terrace at −165 m (ref. 23) occur at sites on the outer shelf margins and are dated between 14 and 18 kyr. Lesser values, around −90 to −110 m are reported from the west Atlantic[24] and Texas Gulf[25]. Variations around the globe are to be expected as a result of adjustment to glacial/interglacial changes of ice and ocean volumes[26-28], although the magnitude of predicted variation differs from one geophysical model to another. The sea-level change between 18 kyr and the present on a broad shelf would be expected to be larger than that recorded on a dipstick-type margin such as the Huon Peninsula[28-30], so that 150 m may be an overestimate of the 18-kyr level at Huon. Undated evidence does occur at Huon in the form of a submerged terrace running along the submarine margin. This is narrow and coraline where it occurs in front of coral terraces, and broad and gravelly where it lies off the flank of a broad deltaic plain[11]. Correcting its level for local uplift puts the sea level at −130 m for each locality[11]. In view of this consistency, we use this estimate of −130 m in our subsequent discussion.

The $\delta^{18}O$ record from core V19-30, based on *Uvigerina senticosa*, is shown in Fig. 1*b*. The original sampling interval of 3 cm corresponds to ~500 yr on average although this value varies down the core as accumulation rate varies[6,31]. Figure 1*b* shows the record using a timescale that was developed by the SPECMAP project[32], and smoothed using a three-point running mean. This timescale was developed iteratively, the starting point being radiometric age determinations both in marine sediments and in coral terraces. The final timescale is developed by tuning the initial record on the basis of its relationship to orbital precession, obliquity and eccentricity functions[32,33]. Although the final timescale is not dependent in detail on particular radiometric dates, the modifications are within the uncertainties of the age estimates at all points[32,33]. In fact, the orbital theory does not provide sufficient constraints on the timescale within stage 3 (in the range 30-60 kyr BP) so that no significant departures from the chronology implied by direct radiometric dating have been used in this interval.

We consider that for the part of the record older than stage 3, the orbitally tuned timescale should be used to refine the age estimates for the Huon Peninsula reefs, on the grounds that independent lines of evidence converge in support of this mechanism, and that the assumption of orbital forcing places constraints on the timescale from 70 kyr back past the useful limits of U-series dating that are much tighter than those imposed by the analytical uncertainties on radiometric dates in this interval. Figure 1*c* shows the Huon sea-level record as re-estimated on this basis, each sea-level maximum and minimum has been assigned the same age as the assumed correlative in the V19-30 record. The amplitude of some peaks differs significantly between Fig. 1*a* and *c* because the sea-level estimate for any point in the sequence depends on the assumed age for that point. The sea level also depends on the value of the uplift rate adopted in each section which depends on the age assumed for reef VII. It also depends on whether this age, and the 6-m calibration height, is assigned to terrace VIIa or VIIb. Finally in traverses containing a single feature for reef VII the uplift rate depends on whether this feature is assumed to represent VIIa or VIIb. Because oxygen isotope studies clearly associate reef VIIa (the older) with substage 5e (ref. 17), and also associate the undifferentiated but dated level in Barbados[15,16] and in Curacao with 5e, it must be assumed that VIIa is the calibration level to make a comparison consistent with the deep-sea ^{18}O record. There are various sources of data from the Huon Peninsula[9-14], so to remove confusion, Table 1 lists reef crest heights from each surveyed traverse together with the age that we have adopted for each, and the resulting sea-level estimate.

Before 130 kyr the sea-level curve derived from marine terraces is subject to larger uncertainties because both the assigned ages and assumed uplift rates become less secure. However, for

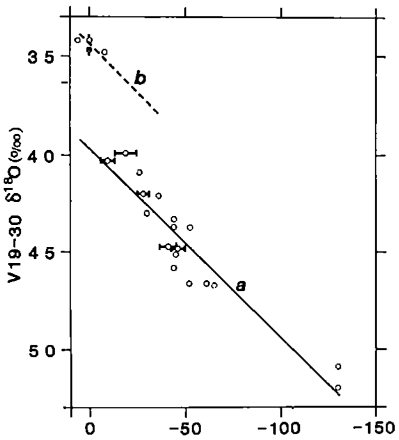

Fig 2 Huon sea level (recalculated age model, Fig 1*c*) versus equivalent ^{18}O in V19-30, from data in Table 2 Regression line *a*, $\delta^{18}O = 3\ 96 - 0\ 0097$ sea level, fitted to all points from 17 to 112 kyr, $r^2 = 0\ 86$ Line *b* is drawn parallel to the regression line *a*, but passes the area at top left which encompasses data for 5e (124 kyr) and recent (6 kyr-present)

the past 130 kyr we regard Fig 1*c* as the best sea-level record available for the New Guinea/Australian region (noting that the magnitude of sea-level oscillations may be smaller in other parts of the world as a result of isostatic factors) Within the past 130 kyr the greatest uncertainty relates to the reef IVb-IIIa area where the isotopic record shows little structure (see Table 2), in Fig 1*c* a gap is shown over this part Table 2 lists sea levels for most turning points in Fig 1*a*,*c* as well as the ^{18}O values for corresponding points in V19-30

Comparing Fig 1*b* with Fig 1*c*, it is particularly striking that the sea-level peaks within the last glacial cycle, and especially the well controlled peaks at ~106 and 81 kyr, are relatively closer to the Recent and 124-kyr levels than the equivalent ^{18}O values Figure 2 plots sea level against ^{18}O for all established turning points in Fig 1*c* A cluster of points around zero sea level and +3 4‰ corresponds to full interglacial stage 1 and substage 5e A single line cannot be drawn through all data points that is, there is not a simple linear relationship between sea level and ^{18}O in benthic foraminifera Although this situation could result in part from temporal variations in the isotopic composition of the stored ice, this cannot be the chief factor involved If the 0 6‰ isotopic difference between the interglacial points and the two terraces at ~−20 m were to be explained solely in terms of the removal of isotopically light water from the ocean, this would necessitate ice with an ^{18}O content of ~100‰ The lightest ice in Antarctica is ~−60‰[34,35] The average isotopic composition of the ice in an ice sheet depends mainly on the isotopic composition of the snow falling in the cold central region, which depends on the air temperature and hence mainly on the altitude of the central part Thus the first ice accumulating in small Northern hemisphere ice sheets must have been less isotopically light than was the ice stored in the fully developed ice sheet

One possible solution to this difficulty could be that a significant amount of isotopically light floating ice accumulated[36-38] This would change the ocean isotopic composition without having any effect on sea level The only place where a sufficient quantity of floating ice can plausibly be envisaged is the Arctic Ocean, the detailed and continuous stratigraphic sequences that have recently been documented from deep-sea cores in the Eastern Arctic Basin[39] exclude the possibility that this ingenious idea is correct, at least for the 18 kyr glacial maximum The data in Fig 2 require a mechanism that operated during warm substages 5a and 5c as well as at glacial maximum time

A more probable explanation is that this isotopic shift results from a temperature effect on the isotopic composition of the benthic foraminifera analysed A best-fit line through all the glacial points in Fig 2 intercepts the axis at ~+3 95‰ (line *a* on Fig 2), requiring a temperature difference of ~2 °C The slope of this line is 0 97‰ per 10 m (very close to the generally adopted value[40]) which corresponds to a mean ^{18}O content for the abstracted water of ~−35‰, a reasonable value

Deviations from this regression are still significant, in Fig 3 we examine the temporal pattern of the deviations from line *b* on Fig 2, which parallels line *a* and passes the Recent points, to evaluate the relative contributions of varying sea level, deep-water temperature and ice isotopic composition to the ^{18}O record For convenience, Fig 3 has a scale representing deep-water potential temperature at the site of core V19-30 (refs 41, 42) This scale would be valid only if there were no variation in the isotopic composition of stored ice-sheet ice If this assumption is correct, Pacific deep waters cooled rapidly to ~0 °C by ~110 kyr, and then cooled more slowly to ~−1 °C around 40 kyr, warming to 0 °C at 18 kyr and then to 1 5 °C at present Although a warming at 18 kyr seems surprising, one model has predicted such an effect[43] However, an alternative would be that the stored ice (which includes Antarctic ice) became gradually more negative between 110 and 30 kyr (ref 44), and that the very rapid advance of ice to lower latitudes between 30 and 20 kyr involved more temperate ice that was less isotopically negative Further work will be needed to establish the possible contribution of temperature variability to the pattern in the glacial section of Fig 3, we regard the overall glacial cooling of Pacific deep water by 1 5 °C that is implied, as inescapable

It would be useful to compare the older sections of the Huon and V19-30 records, but this is not possible for several reasons (1) there is no earlier sea-level datum comparable to that at 124 kyr to use for uplift-rate calibration, (2) the errors in $^{230}Th/^{234}U$ dates become more serious in this interval, Fig 1 suggests that this method may actually overestimate ages in the 180-240 kyr age range, (3) only two sections have been surveyed for the pre-5e part of the Huon record It is regrettable that the morphostratigraphy of this important Upper Quaternary area has been surveyed and described by only one geologist (J C)

Table 2 Huon sea levels and V19-30 ^{18}O values

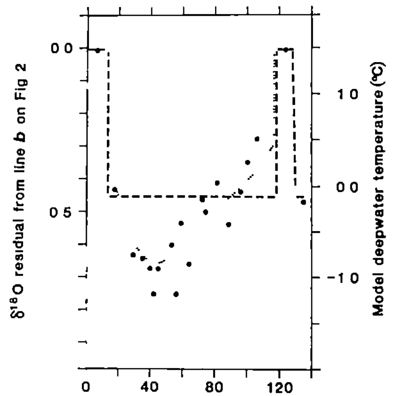

Fig 3 Residuals from line *b* (Fig 2) versus estimated age Scale to right shows calculated potential temperature at the sea floor at the site of core V19-30, if this line is interpreted as the correct relationship between sea level and ocean $\delta^{18}O$, and deviations from the line ascribed to temperature Heavy dashed line is our preferred interpretation of the temperature record, the light dotted line is an alternative

No other area is known where the details of sea-level change are available for field examination

We conclude that deep waters in the Pacific Ocean were ~1 5 °C cooler in glacial and interstadial times than in the short (~10 kyr duration) interglacials of substage 5e and the present One interpretation of our analysis is that deep water was coldest at ~40 kyr and that almost 1 °C of warming occurred by the glacial maximum and a further 1 5 °C of warming subsequently Alternatively, part of the observed detail resulted from changes in the isotopic composition of the ice sheets, with the deep Pacific remaining ~1 5 °C cooler than the present temperature throughout the glacial Regardless of this detail, massive cooling of the already cold abyssal ocean must be considered an important aspect of the ice age climate

Predicting aqueous aluminium concentrations in natural waters

Christopher S. Cronan, William J. Walker* & Paul R. Bloom†

Aluminium is a *p*H-sensitive element that can cause acute toxicity symptoms in some organisms at aqueous activities of 10 μM or less[1–3]. Scientists working on agricultural systems have long been concerned with the deleterious effects of aluminium on crop roots[4,5]. More recently, environmental scientists have reported a potentially harmful biogeochemical link between acidic deposition onto forest soils and aluminium toxicity in forest and aquatic communities of northeastern North America and northern Europe[6–8] Because of this general interest in aluminium toxicity as an environmental threat, there have been renewed efforts to model the chemistry and transport of aqueous aluminium in soils and surface waters. Here we propose that much of the spatial and temporal variability in aqueous aluminium chemistry can be accounted for by a two-component equilibrium model involving a solid-phase humic adsorbent and an aluminium trihydroxide mineral phase. Inputs for the model are solution *p*H, copper-extractable organic aluminium and the titratable carboxyl content of soil humus.

Several workers[9,10] have found that [Al^{3+}] (aquo aluminium ion activity) in surface waters can be predicted accurately as a function of *p*H using an aluminium trihydroxide solubility relationship However, other reports[11–13] have presented data revealing aluminium concentrations that are much lower than predicted—that is, despite *p*H values less than 4 5 and elevated concentrations of complexing organic ligands, the solutions contained low concentrations of soluble aluminium This illustrates the failure of existing geochemical models to account for all the major variations in [Al^{3+}] and we refer to it as the 'paradox of aluminium undersaturation'

Figure 1 shows [Al^{3+}] for a variety of natural waters from North America and northern Europe The expected pAl^{3+} values for solutions in equilibrium with natural gibbsite and amorphous $Al(OH)_3$ are also shown As illustrated, there are three major points where observed and predicted aqueous aluminium activities diverge the upper soil rooting zone, downstream of wetlands and during stream peak flows While it has been suggested that these cases of lowered [Al^{3+}] are the result of kinetic constraints on the dissolution of mineral aluminium[14], there have been no rigorous efforts to confirm the kinetic hypothesis in natural systems In this study, our objective was to derive a model that could account for these 'undersaturated'

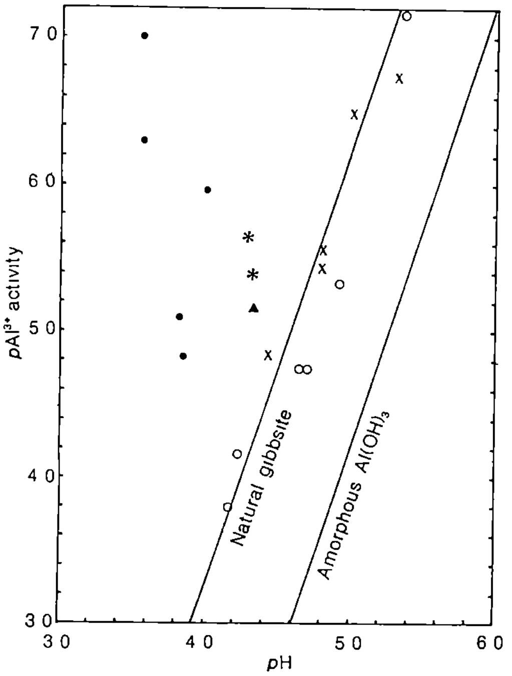

Fig 1 Aquo aluminium activity as a function of pH for a variety of natural waters from North America and Europe Field samples include upper O/A horizon soil solutions (●), lower B/C horizon soil solutions (○), wetland drainage (∗), stream storm flow (▲), and stream baseflow (×) from the following watersheds Woods Lake, New York, Huntington Forest, New York, Pancake-Hall Creek, New York, Solling spruce forest, West Germany, Plastic Lake, Ontario, Lange Bramke, West Germany, Camp Branch, Tennessee, Birkenes, Norway and Lake Gardsjon, Sweden (C S C and C L Schofield, unpublished data)

waters, so that [Al^{3+}] could be predicted across the range of inorganic and organic environments illustrated in Fig 1

Soil and solution chemistry data for this study were obtained using methods described in Table 1 Laboratory experiments were conducted with field-moist, 2 mm sieved forest floor horizons (Oi and Oa)[15] from contrasting northern and southern watersheds in the United States and Canada Aqueous aluminium ion activities were estimated using the GEOCHEM program[16], appropriate thermodynamic constants[17], and the following mass balance equation

$$Al^{3+} = \mathrm{MAL} - \mathrm{MOAL} - Al(OH)_x^{3-x^+}$$
$$-(\text{complexes of } F^- \text{ and } SO_4^{2-})$$

where,

MAL = total monomeric aluminium

MOAL = organic monomeric aluminium

As shown in Fig 1, many of the data points from natural waters lie between the solubility lines for gibbsite and amorphous $Al(OH)_3$ This general pattern agrees with the results of previous studies[10,18] and implies that [Al^{3+}] in these waters may be largely controlled by an aluminium trihydroxide solid phase In order to model solution aluminium chemistry for these types of waters, one can take an average solubility product of $\log K^0 = 8\ 77$, corresponding to natural gibbsite[18] or interlayer aluminium hydroxide[19] Then [Al^{3+}] in solution can be related to the aluminium hydroxide solid-phase by the following relationship

$$\log[Al^{3+}] = 8\ 77 - 3\,pH \qquad (1)$$

Combining this with measured concentrations of complexing ligands and appropriate thermodynamic data[17], it is possible to estimate the equilibrium distribution of inorganic aqueous aluminium

Table 1 Apparent solubility expressions for predicting Al^{3+} activity in the presence of soil organic matter at different bound aluminium ratios

Bound aluminium ratio	Slope	Intercept	Solubility expression	pAl^{3+} at pH 4 40
0–0 10	0 40	3 62	$pAl = 0\ 40(pH) + 3\ 62$	5 38
0 20–0 30	0 60	2 52	$pAl = 0\ 60(pH) + 2\ 52$	5 16
0 60–0 70	1 04	0 26	$pAl = 1\ 04(pH) + 0\ 26$	4 84
0 90–1 00	1 34	−1 28	$pAl = 1\ 34(pH) - 1\ 28$	4 62

Calculated values of pAl^{3+} at pH 4 40 are illustrated for each case Regressions are based on Oi and Oa samples from a representative Adirondack Spodosol Organically bound Al in each soil horizon was determined by extraction with 0 5 M $CuCl_2$, followed by ICP-AES analysis of Al (ref 21) Subsamples of each soil were hydrogen saturated with 1 M HCl[11] and were then titrated under nitrogen to pH 7 0 in 2×10^{-3} M $CaCl_2$ with 0 01 M NaOH Titratable acidity to pH 7 was used as an operational estimate of RCOOH groups The bound Al ratio for each native soil horizon was computed as the equivalents of Cu-extractable Al per unit organic matter divided by the equivalents of RCOOH per unit organic matter Based upon the titration data, subsamples of Oi and Oa forest floor horizons were amended with $Al(NO_3)_3$ to produce a range of bound Al ratios from 0 1 to 1 0 For each soil horizon and bound Al ratio, subsamples were augmented with 2×10^{-3} M $CaCl_2$ and were adjusted with HCl or NaOH to yield a pH range from 3 0 to 5 0 In addition, untreated control subsamples of all native soil horizons were prepared as soil pastes in H_2SO_4(pH 4 0) augmented with 2×10^{-3} M $CaCl_2$ All soil mixtures were then equilibrated for 48 h, followed by mechanical vacuum extraction through acid washed cellulose pulp Aqueous monomeric inorganic and organic Al fractions were estimated using ion exchange separation, reaction with 8-hydroxyquinoline at pH 8 3, and spectrophotometric determination at 395 nm[22] Inorganic anions were measured with ion chromatography

Earlier studies have emphasized the potential importance of soil organic matter in controlling aqueous aluminium, and Bloom *et al*[11] suggested that aluminium-hydrogen ion exchange on organic matter controls [Al^{3+}] in acidic surface soils We propose that a general model for predicting aqueous aluminium chemistry must incorporate this type of organic solid phase reaction to account for the zone of extreme undersaturation illustrated in Fig 1

Soil equilibration experiments were used to determine the influence of humic adsorption-desorption reactions on [Al^{3+}] in Oi and Oa organic soil horizons Results indicated that (1) forest floor saturated pastes reached stable levels of [Al^{3+}] in 5 min or less and (2) at solution pH values between 3 0 and 5 0, plots of pAl^{3+} versus pH were approximately linear for discrete ranges of bound aluminium, and [Al^{3+}] increased with increasing percentages of solid-phase aluminium (Fig 2) This pattern indicates that equilibrium conditions can be assumed for these soil horizons and that it is possible to construct [Al^{3+}] apparent solubility lines based upon the bound aluminium ratio and pH

Table 1 shows the best-fit linear regression solubility expressions for the four experimental ranges of bound aluminium ratio shown in Fig 2 Combining these equations, gives the following general solubility expression for predicting aquo aluminium ion activity in natural waters dominated by humic adsorption-desorption reactions

$$pAl^{3+} = b(pH) + c \qquad (2)$$

where b is the slope = 1 05 × (bound Al ratio) + 0 345, and c is the intercept = −(5 47 × (bound Al ratio)) + 3 879 This empirical regression equation confirms the strong relationship between [Al^{3+}], solution pH and carboxyl-bound Al, and provides a simple means of predicting [Al^{3+}] in acidic organic soil horizons

The same data for aluminium solubility can be modelled more formally using the modified mass action expression derived by Langmuir[20] Given the reaction, $3H^+ + AlX \rightleftharpoons H_3X + Al^{3+}$, the empirical exchange function would be $K_{ex} = ([Al^{3+}]/[H^+]^3)(H_3X/AlX)^n$, where K_{ex} and n are constants, the brackets denote activities of the ions, and AlX and H_3X are their mole fractions on organic sorbent X Log-linearization of this expression yields

$$\log([Al^{3+}]/[H^+]^3) = \log K_{ex} + n \log(AlX/H_3X) \qquad (3)$$

Table 2 Model validation for a variety of North American forest soils

Observed values for pAl^{3+} were obtained with soil paste extracts, while calculated pAl^{+3} values were derived with either the humic-aluminium or aluminium trihydroxide model components The former model (equation 2) was calibrated with experimental data from the Pancake-Hall Adirondack watershed, the apparent solubility lines from that Spodosol were broadly representative of the other soils

* Close agreement (±0 4) between pAl^{3+} observed and humic-Al model

† Close agreement (±0 4) between pAl^{3+} observed and inorganic solubility model

Table 2 contains a summary of the model validation results obtained for a number of soils from North America with bound aluminium ratios ranging from 0 03 to 1 00 Using the actual bound aluminium ratio and solution pH for each soil sample, the humic-aluminium partition model was used to predict solution $[Al^{3+}]$ for the untreated native soil horizons from each watershed These predictions were compared with observed soil paste $[Al^{3+}]$ values and with predictions from the $Al(OH)_3$ solubility model The fit of a model was judged satisfactory if it correctly predicted pAl^{3+} to within ±0 4 units The humic-aluminium model was successful in predicting the pAl^{3+} in all the O horizons with the exception of the sample from the Missouri watershed Whereas the $Al(OH)_3$ solubility model provided an accurate prediction for pAl^{3+} in stream water at low flow, the model was unable to predict pAl^{3+} correctly in any of the O horizons

We examined the region of the stability field where the humic-aluminum and $Al(OH)_3$ apparent solubility lines intersect The Oi horizon data in Table 2 shows that surface organic horizons with higher pH (>4 8 to 5 0) and low mineral content will often follow the humic-aluminum solubility line and can actually maintain oversaturation with respect to the solubility of interlayer $Al(OH)_3$ This is probably due to the scarcity of clay nucleation sites in these horizons and interference of soluble organic matter in the formation of mineral precipitates However, as the pH is raised above about 5 2, it is likely that amorphous $Al(OH)_3$ forms by homogeneous nucleation Thus, the upper limit of applicability for the humic-aluminium model is probably about pH 5 2

In practice, this model will typically apply to surface organic horizons and peaty hydrologic source areas, whereas the inorganic solubility model will be appropriate for lower mineral soil horizons and for the groundwater zone During peak flows in lower order streams, it is likely that stream water chemistry will be strongly influenced by 'undersaturated' lateral flow derived from organic-rich surface soil horizons Under these conditions, where streamwater results from mixing of lateral flow and baseflow, it will be necessary to combine accurate hydrologic flux estimates with these chemical models

The model presented here can account for much of the variation in $[Al^{3+}]$ observed in natural waters draining different inorganic and organic environments Although we previously suspected that waters undersaturated in $[Al^{3+}]$ could result from kinetic constraints on Al dissolution and desorption, our results suggest that these waters may actually be in equilibrium with a solid phase humic adsorbent With further testing and development, this model may be suitable for application to studies of aluminium transport associated with acid deposition

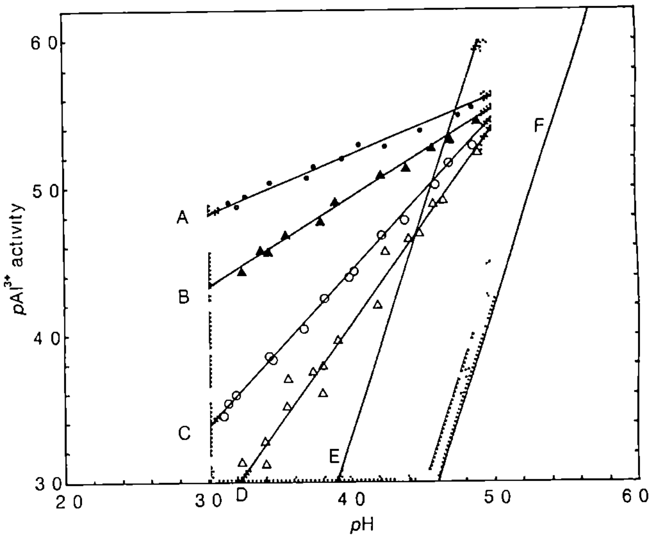

Fig 2 Stability field for apparent aluminium solubility in the presence of soil humic material in the pH range 3 0 to 5 0 The points along each apparent solubility line represent equilibrium pAl^{3+} values for Oi and Oa horizons from an Adirondack Spodosol These horizons were pretreated to yield the following four different ranges of bound aluminium ratio line A = 0 to 0 1, line B = 0 2 to 0 3, line C = 0 6 to 0 7, and line D = 0 9 to 1 0 The solubility lines for interlayer (E) and amorphous $Al(OH)_3$ (F) at 25 °C are shown for reference

We thank C L Schofield for contributing to many of the Al speciation measurements that provoked this investigation and B Lee for typing the manuscript This is a contribution from the ALBIOS project, supported by contract RP 2365 from the Electric Power Research Institute

A new Miocene hominoid from Kenya

R. E. Leakey & M. G. Leakey

National Museums of Kenya, PO Box 40658, Nairobi, Kenya

A newly discovered early Miocene site in northern Kenya has yielded a partial cranium, several mandibles, isolated teeth and some associated postcranial elements of a large ape that is distinct from other known African and Asian hominoids. The new genus implies a greater complexity in the relationships between the Miocene hominoids and may offer useful evidence concerning the origin of the Asiatic and African large apes. The genus *Sivapithecus* has been reported from East Africa[1] but the new material supports the hypothesis that this genus only occurs beyond Africa[2], although having an African ancestry. The new genus presents a mosaic of characters which suggest an early radiation of Miocene hominoids.

The specimens were found in exposed sediments along the western side of Lake Turkana in northern Kenya in 1985–86 at a small but rich early Miocene locality named Kalodirr (3°20′ N, 35°40′ E). Approximately 10 km south there are other early Miocene fossil-bearing sediments known by several names, including Losodok[3], Moruaret Hill[4], and Moruarot[3,5,6], which probably belong to the same sequence of Miocene deposits. It has not yet been possible to date the locality but we estimate the age may be between 16 and 18 million years based on faunal comparison. Almost all the elements of the mammalian macrofauna recovered are represented at Rusinga (Hiwegi Formation)[7] and the fauna is similar to that from Buluk[1] and Moruarot[6] (Table 1), but three hominoid taxa were recovered all representing new genera. The largest is described here.

Order Primates
Superfamily Hominoidea
Family incertae sedis
Afropithecus gen. nov.

Generic diagnosis. A large hominoid with long narrow palate, distinguished from all known large hominoids by the long distinct muzzle and steeply inclined frontal such that in lateral profile, prosthion, rhinion, glabella and bregma are on almost the same line, and by the corresponding obliquity of the mandibular ramus. It differs from *Sivapithecus, Ramapithecus, Kenya-pithecus, Proconsul* and *Rangwapithecus* in the lingual and buccal basal flare of the upper molars and premolars, particularly P^4, so that the cusp tips tend to be relatively close compared to the cervical width. It differs from *Sivapithecus, Ramapithecus* and *Kenyapithecus* in the buccolingually expanded premolars, the pronounced cingulum bordering the protocone of the upper molars mesially and lingually and the buccolingually broad lower incisors, particularly I_2. It differs from *Rangwapithecus* in the buccolingually expanded upper premolars, the upper P^4 which is shorter mesiodistally than P^3, the less developed lingual cingulum of the upper molars, the procumbent upper incisors and the long superior aspect of the premaxilla. It differs from the similar sized *Proconsul major* in mandibular morphology particularly the lack of development of the superior transverse torus and the steeply sloping subincisive planum.

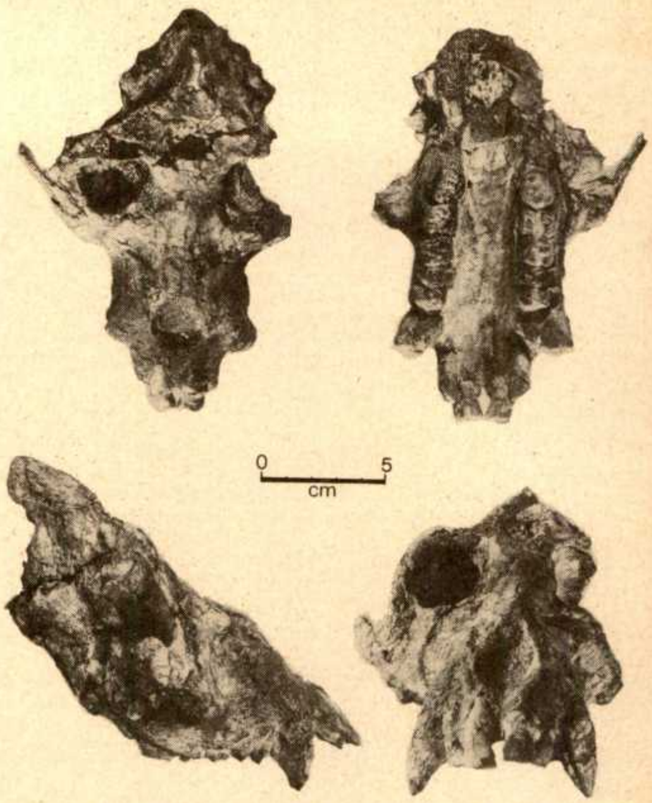

Fig. 1 *Afropithecus turkanensis* cranium, KNM-WK 16999 (type). Above, superior and inferior aspects; below, right lateral and frontal aspects.

Etymology. *Afro* after the continent on which it is found, *pithecos* Greek for ape.

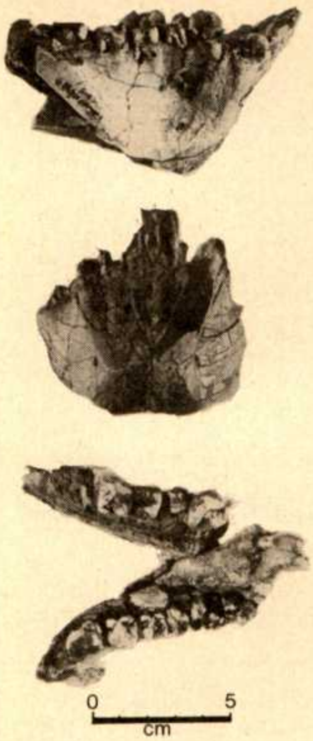

Fig. 2 *Afropithecus turkanensis* mandible, KNM-WK 16840. Above, right lateral aspect; centre, anterior aspect and below, occlusal aspect.

Description. The type specimen, KNM-WK 16999, includes the snout, the facial skeleton, the frontal reaching close to the coronal suture, the pterygoid processes, the sphenoid body, the vomer and the relatively unworn adult dentition.

The palate is shallow, long and narrow and the tooth rows converge posteriorly. The internal nasal aperture is remarkably narrow (15 mm) and high (~18 mm). There is a large (6.5 mm) diastema between the strongly procumbent I^2 and the canine. The enamel surface of the incisors and canines is markedly wrinkled by numerous small vertically running grooves and the occlusal surface of the cheek teeth is covered by numerous wrinkles. The slightly worn central incisors are large and broad while the lateral incisors are relatively small and mediolaterally compressed. The canines are broad and in cross section at the cervix almost circular. Their relative size suggests that the individual was male. The premolars are large, P^3 being larger than P^4. In both the buccal cusp is higher than the lingual and there is marked buccal basal flare. The P^3 has slight lingual basal flare whereas in P^4 this is more marked and the cusp tips are relatively close compared to the basal buccolingual width. $M^1 < M^2 < M^3$ and the molars are broader than they are long (Table 2). On all three molars there is a distinct but short mesial and lingual cingulum extending around the protocone. The enamel cap appears relatively thick judged from the degree of wear before dentine exposure.

The surface bone of the premaxilla is largely replaced by calcite. Its superior aspect is long, forming a gently sloping shelf with a central longitudinal groove. The nasals are long and narrow (13 mm across the widest point) but the tips are lost close to the margin of the small oval pyriform aperture. The left side of the maxilla is best preserved. There is a distinct jugum and posterior to it a small postcanine fossa. On either side of the nasals, anterior to the marked lacrimal foramina, the maxilla is distinctly hollowed. The zygomatic process is deep below the orbit (37 mm) and the inferior border swings markedly upwards from the masseteric tubercle towards the temporal, a striking feature probably related to an unusually high position of the cranial vault. The right orbit is virtually complete and relatively undistorted. It is higher than it is wide and has an asymmetrical outline; the greatest depth (30 mm) is lateral to its longitudinal axis and the greatest width (25 mm) is close to the superior margin. The supraorbital tori are very thin and there is a small but distinct supraorbital notch. The interorbital distance is large (24.5 mm). The marked temporal lines swing sharply towards the midline forming a frontal trigon which rises steeply towards the apex, approximately 52 mm posterior to glabella. There is a distinct, mostly midline frontal sinus, seen through the breaks in the region immediately above glabella. Glabella does not project anterior to the orbits and is weakly developed. In lateral profile, prosthion, rhinion, glabella and bregma are almost in the same line, a feature not observed in any other fossil or living large hominoid.

KNM-WK 16840 (Fig. 2) is the most complete of the mandibular specimens. The body is deep and robust and the tooth row relatively short. The symphysis is deep (60 mm) and the internal surface slopes steeply down to the genial fossa with little development of the transverse tori. The superior anterior aspect is the widest because of the lateral flare of the canines. The narrowest point is at a level with the mental foramen and below this, it widens towards the prominent mental tubercles. The mandibular body is deepest anteriorly (54 mm at the posterior canine alveolar margin) and becomes slightly shallower towards the posterior (44 mm below M2). There is a distinct mandibular fossa. There is a clearly defined and very large digastric fossa. One specimen, KNM-WK 17021, preserves details of the ramus which is set at an oblique angle to the body. There is a slight inferior projection of the mandibular angle.

Several specimens provide details of the lower dentition at various stages of wear (Table 2). The lower incisors are all marked by varying degrees of mesial curvature from the root tip to the crown and the roots are broad labiolingually, particularly I_2. The P_3s are relatively large, rather narrow and sectorial with a slight extension of the enamel onto the buccal face of the mesial root. The P_4s are small compared to the P_3s, low crowned and bicuspid. The molars are slightly inflated buccally and on one specimen, KNM-WK 17024 there is evidence of a slight buccal cingulum. M_3 has a small tuberculum sextum. $M_1 < M_2 < M_3$.

Afropithecus displays characters typical of a variety of Miocene hominoids combined in a single taxon that should also include the large hominoid recently described from Buluk[1]. We

Left tooth dimensions are given except where * indicates right tooth dimensions.

now believe that *Sivapithecus*[8,9] is restricted to Asia including the Siwaliks, Indo-Pakistan[2]. A careful comparison of the mandibular morphology of *Proconsul major* as represented by the material known from Songhor and Koru[10] differs from *Afropithecus* in the strong development of a superior transverse torus and lack of an inferior torus, the long shallow alveolar subincisive planum and the marked increase in size of the lower molars from M_1 to M_3, not seen in *Afropithecus.* The maxillary morphology of *P. major* is poorly represented. The only reasonably complete specimen that may represent this taxon is the Moroto palate and associated facial fragments. Its assignment [10-13] to *P. major* is disputed[14,15] but when the Moroto palate is compared to KNM-WK 16999, the superior aspect of the premaxilla is shorter, the breadth of the nasal aperture is greater, P_4 is less buccolingually expanded and there is no well developed lingual cingulum on the molars.

One weathered maxillary fragment from Moruorot, KNM-LS 7, previously referred to *P. major*[10] was recently designated the type of *Proconsul* (*Xenopithecus*) *hamiltoni*[16]. The two eroded and worn molar crowns[17,18] are both elongated buccolingually whereas those of *Afropithecus* are more square. Together with the limited details of cusp morphology, this suggests that this specimen is not *Afropithecus.* In fact the specimen is so poor that we suggest that the name *P.* (*Xenopithecus*) *hamiltoni* be abandoned.

Afropithecus has been compared with the poorly represented African genus *Kenyapithecus.* Little is known of the maxillary morphology of either the later species, *K. wickeri,* or the earlier species, *K. africanus,* but both differ from *Afropithecus* in the dentition, particularly the lack of buccal basal flare on the molars and premolars, the premolars that are not buccolingually expanded and the molars that lack a marked cingulum bordering the protocone. Similarities are apparent in the root of the zygomatic which leaves the maxilla above M^1 and the postcanine fossa of *K. wickeri.* The mandible of *K. wickeri* is known but differs from *Afropithecus* in having a relatively shallow body with a shallow rather gently sloping subincisive planum.

The phyletic status of the large hominoids from the Miocene of Europe is not agreed[19-21] but we have considered the published descriptions and made direct comparisons between *Afropithecus* and casts available to us of the European fossils and we are satisfied that *Afropithecus* is quite distinct from the European species of *Dryopithecus*[22], *Ouranopithecus*[21,23], *Rudapithecus* and *Bodvapithecus*[22].

Afropithecus resembles the specimen GSP 15000 from the Siwaliks[24] attributed to *Sivapithecus sivalensis* (formally *S. indicus*[20]) in the postcanine fossa, the large procumbent central incisors, the relatively small asymmetrical lateral incisors, the long superior aspect of the premaxilla, the small suprorbital tori and the high hafting of the cranial vault onto the face. It differs in the distinct snout and the extraordinary profile with the almost linear alignment of prosthion, rhinion and glabella. These differences also apply when a comparison is made with the known large hominoids from Lufeng[25]. The Lufeng specimens resemble *Afropithecus,* however, in the conformation of the temporal lines and the wide interorbital distance. Details of sub-nasal morphology which have been used as a basis for discriminating between various hominoids[26,27] cannot be discerned on KNM-WK 16999.

In conclusion, the mosaic of characters represented in the new genus, which precludes its inclusion in any of the Miocene hominoid families previously defined, suggests a greater complexity in the early Miocene than was previously apparent. The absence of *Afropithecus* from the richly fossiliferous localities of western Kenya where fossil primates are common may indicate ecological or temporal factors. Further work at Kalodirr and other Miocene sites in northern Kenya will investigate these questions.

We thank the Government of Kenya and the Governors of the National Museums of Kenya. The research was financed by the National Museums of Kenya and contributions from The Maytag Family Foundation, Mr and Mrs L. Newitt and the National Geographic Society of Washington, D.C. We also thank Bw Kamoya Kimeu and his prospecting team, particularly Bw Wambua Mangao who found the type specimen, Bw Joseph Mataba who prepared the majority of the specimens, Dr L.

Jacobs, P. Kat and Ms K. Stewart who identified the microfauna, molluscs and fish respectively, and Dr Alan Walker who assisted in many ways.

A second new Miocene hominoid from Kenya

R. E. Leakey & M. G. Leakey

National Museums of Kenya, PO Box 40658, Nairobi, Kenya

A recently discovered early Miocene site in northern Kenya (see preceding paper[1]) has yielded a number of important fossil hominoid specimens including a partial cranium, mandible and postcranial remains of a medium-sized ape that is distinct from all previously reported genera. The relationship of this taxon to other known hominoids is not clear. A new genus of large hominoid was found at the same site[1]. The recovery of two new genera of Miocene hominoids which are apparently not represented at the well known and rich Miocene localities of western Kenya may indicate that a different ecology is being sampled.

The specimens were found in 1985-6 at a new Miocene locality named Kalodirr on the western shores of Lake Turkana. The site has not been dated but a faunal comparison suggests it may be between 16 and 18 million years[1].

Order Primates
Superfamily Hominoidea
Family incertae sedis
Turkanapithecus gen. nov.

Generic diagnosis. A shortfaced small hominoid approximately the size of a *Colobus polykomos*. It is distinguished from all known hominoids by the upper M^2 s, which have an additional cuspule between the pronounced and beaded mesial and lingual cingula, and the upper molars and P^4 which have small additional cuspules associated with a small buccal cingulum bordering the paracone. It is distinguished from the Oreopithecidae by the relatively low relief of the dental occlusal surface, upper molars not mesiodistally elongated and lower molars not long and narrow, without buccolingual waisting and lacking a centroconid. It is distinguished from the larger *Rangwapithecus gordoni* by the upper M^3 approximately the same size or smaller than M^2 and the upper P^4 smaller than P^3. It is distinguished from the slightly larger *Proconsul africanus* by the distinct snout, the wide interorbital distance, the relatively thick supraorbital tori, the broad nasals, the relatively broad and low mandibular ramus and the upper premolars and molars not buccolingually expanded. It is distinguished from the similar sized *Pliopithecus vindobonensis* by the distinct snout, the long nasals, and the zygomatic process of the maxilla approximately vertical with no protruding inferior orbital margin.

Table 1 *Turkanapithecus* tooth dimensions (mm)

	Acc. no.	Tooth	mesiodistal	buccolingual
Upper	KNM-WK 16950	C*	10.0	7.9
		P^3	6.8	8.0
	KNM-WK 16957	P^3	5.9	7.7
	KNM-WK 16950	P^4	5.5	—
		M^1	7.0	7.5
		M^{2*}	8.6	9.2
		M^3	8.5	8.9
		$C-M^{3*}$	44.0	—
		P^3-M^3	35.2	—
		M^1-M^3	24.0	—
Lower	KNM-WK 16950	M_2	9.2	7.0
		M_3*	9.2	7.5

Left tooth dimensions are given except where * denotes right tooth dimensions.

Etymology. After Lake Turkana and *pithecos*, Greek for ape.

Turkanapithecus kalakolensis sp. nov.

Species diagnosis. As for genus.

Type specimen. KNM-WK 16950A and B, a partial cranium and mandible (Figs 1 and 2).

Hypodigm.

KNM-WK 16950I-X postcranial elements probably associated with the type specimen: right femur, proximal and distal left radius, left metacarpal I and fragments of phalanges, rib and vertebrae

KNM-WK 16957 fragment of maxilla.

Etymology. After the River Kalakol of which the Kalodirr is a tributary.

Description: The type cranium, KNM-WK 16950, which is slightly smaller than the female *Proconsul africanus* skull (KNM-RU 7290) is reasonably complete and includes the facial skeleton, partial calvaria and examples of all the permanent upper teeth except the incisors. The associated mandible preserves much of the left ramus, the mandibular body and the left M_2 and right M_3. A complete right femur, fragments of proximal and distal left radius, ribs, vertebrae and foot bones are most probably associated with the cranium and mandible but there is a slight element of uncertainty concerning this association, so they are not designated as part of the type material.

The palate is rather shallow and narrow with the tooth rows converging towards the back. A crack, 2.2 mm wide, runs along the centre of the palate making it appear broader than it was. Judged from the position of the back of the palate and the length of the remaining right pterygoid, the internal nasal aperture was high and narrow. The teeth (Table 1) are moderately to heavily worn. The right upper canine is relatively large suggesting the individual was male. The right P^4 is missing and was lost in life causing some malocclusion; the wear on the right P^3 is greater than on either the left P^3 or the left P^4. P^3 is significantly larger than P^4, both are wide buccolingually. The upper molars are rather square in outline but wider than they are long. $M^1 < M^3 < M^2$. The morphology of the M^1s is obscured by wear, dentine being exposed over almost the entire occlusal surface. The M^2s are distinctive, having marked, beaded mesial and lingual cingula with an unusual accessory cuspule between them. The M^3s

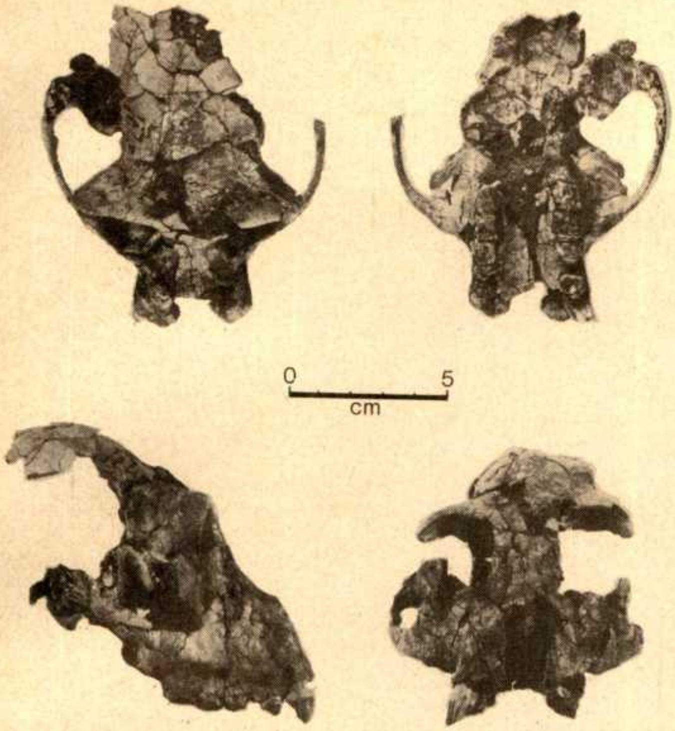

Fig. 1 *Turkanapithecus kalakolensis* cranium, KNM-WK 16950A (type). Above, superior and inferior aspects; below, right lateral and frontal aspects.

are more worn than the M^2s, probably due to the apparent high set of the lower M_3s. P^4 to M^3 have small buccal cingula bordering the paracone each with an additional cuspule variably developed.

The premaxilla is largely missing. The pyriform aperture was of moderate size and oval (approx. 17 mm wide). The nasal bones are large, being long (maximum length 27 mm) but also fairly broad (maximum width 14 mm across both). The right maxilla is the best preserved; there is a slight canine jugum but no postcanine fossa. The lower border of the root of the zygomatic process is about 7 mm above M^1. The zygomatic process is relatively deep below the orbit with the lower border being close to vertical beneath the lower orbital margin. The orbits are incomplete and slightly distorted; they were probably almost circular but slightly higher (approx 24 mm) than wide (approx 22 mm). There is only the slightest supraorbital notch and no development of a supraorbital sulcus. The interorbital distance is large (21 mm). In the region of glabella the bone is crushed and fractured exposing a fairly well developed frontal sinus. The frontal is distorted on the left side lateral to the rather indistinct temporal line. The right temporal line is strongly developed passing initially towards the midline almost parallel with the orbital margin before curving sharply towards the posterior. Little of the parietals is preserved. The occipital area is damaged but there is a fragment that includes the posterolateral margins of the foramen magnum with most of both condyles and a small portion of bone extending to the nuchal crest. The temporal bone is partially preserved on the right and includes the mandibular fossa, the postglenoid process and the zygomatic process which attaches to the zygomatic.

The mandible is relatively complete particularly on the left side which lacks only some bone in the regions of the angle of the mandible, the coronoid process and the canine alveolus. The mandible is gracile and deeper at the symphysis (28 mm) than below M_2 (21 mm). The internal surface of the symphysis slopes evenly down as a narrow, slightly concave subincisive planum. There is virtually no development of a superior or inferior transverse torus. A small digastric fossa is clearly defined on the right. The anterior root of the broad ascending ramus originates close to M_2. The mandibular condyle is relatively large and rounded being broad mediolaterally and wide anteroposteriorly. Only two lower teeth were recovered, the moderately worn left M_2 and the right M_3. The lingual cusps are positioned slightly distal to the buccal and the talonid basin is large. On M_2, both the mesial and distal foveae are clearly defined and the hypoconulid was probably large.

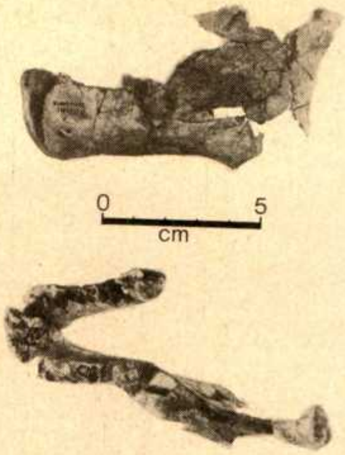

Fig. 2 *Turkanapithecus kalakolensis* mandible, KNM-WK 16950B (type). Above, left lateral and below, occlusal aspects.

The phylogenetic relationship of *Turkanapithecus* to other known fossil hominoids is not clear. The cranial morphology has been compared with the only other similar sized African Miocene hominoid for which a skull is known, *Proconsul africanus*[2,3] and there are important differences. *Turkanapithecus* is distinguished by the distinct and rather 'square' maxilla, the larger pyriform aperture, the longer nasals which widen at either end, the greater depth of the zygomatic process of the maxilla beneath the orbit, the root of the zygomatic process above M^1 not M^2, the wider interorbital distance, the distinct supraorbital tori and the rather flat supraglabella region. The mandibular ramus is lower and wider anteroposteriorly and the condyle is knoblike and not elongated mediolaterally as in *P. africanus*. Comparison with the similar sized cranium of *Pliopithecus vindobonensis* from the Middle Miocene of Europe[4,5] also shows differences in the 'square' maxilla of *Turkanapithecus*, the long nasals and the zygomatic process of the maxilla roughly vertical with no protruding inferior orbital margin. The dentition differs from both *Pliopithecus* and *Proconsul* in the features mentioned in the diagnosis.

The dentition has been compared with some isolated teeth from Maboko which have recently been attributed to the previously monospecific family, the Oreopithecidae[6] and included in a new genus to which *Rangwapithecus vancouveringi* is also referred[7]. They are considered to have some affinities with *Rangwapithecus gordoni*. These teeth may be readily distinguished from *Turkanapithecus* in the high cusped elongated molars. Szalay and Delson[8] suggest that *Oreopithecus* has cercopithecoid affinities on the basis of a number of shared derived characters of the dentition. These features are those which distinguish *Oreopithecus* from *Turkanapithecus*.

Unfortunately little is known of the cranial morphology of the Miocene small bodied apes. *Limnopithecus*, *Dendropithecus* and *Micropithecus*[9,10] but the dentition clearly separates these genera from *Turkanapithecus*. Although ecological differences may be a factor, it is puzzling, if our age estimates are correct, that *Turkanapitheus* has not been recorded previously from any of the known Miocene sites in western Kenya where fossil apes are common. This relatively complete material from Kalodirr is important in the new evidence it provides of greater diversity in the Miocene Hominoidea.

We thank the Government of Kenya and the Governors of the National Museums of Kenya. The research was financed by the National Museums of Kenya and contributions from The Maytag Family Foundation, Mr and Mrs L. Newitt and the National Geographic Society of Washington, D.C. We thank Bw. Kamoya Kimeu and his prospecting team who discovered all the fossils described and particularly Bw. Wambua Mangao who found the type specimen. Bw. Joseph Mataba prepared the specimens and Dr Alan Walker assisted in many ways.

Vegetation, climatic and floral changes at the Cretaceous-Tertiary boundary

Jack A. Wolfe & Garland R. Upchurch, Jr

US Geological Survey, MS-919, Box 25046, Federal Center,
Denver, Colorado 80225, USA

The western interior of North America has the only known non-marine sections that contain the iridium-rich clay interpreted as the Cretaceous–Tertiary (K–T) boundary[1–7]. Because vegetation and climate can be directly inferred from physiognomy of leaves[8–15] and because leaf species typically represent low taxonomic categories, studies of leaf floras in these sections provide data on the effects of a terminal Cretaceous event on the land flora, vegetation and climate. A previous study based on detailed sampling of leaves and their dispersed cuticle[16] in the Raton Basin provides a framework for interpretation of other leaf sequences over 20 degrees of latitude. We conclude that at the boundary there were: (1) high levels of extinction in the south and low levels in the north; (2) major ecological disruption followed by long-term vegetational changes that mimicked normal ecological succession; (3) a major increase in precipitation; and (4) a brief, low-temperature excursion, which supports models of an 'impact winter'.

Latest Cretaceous (late Maestrichtian, equivalent to Lancian; Phase 1 (ref. 16)) vegetation from palaeolatitude[17] 46° to >56 °N (Fig. 1) was dominantly broad-leaved evergreen (Table 1). In the south small leaf size, paucity of drip tips and thick cuticles with cutinized hairs on both surfaces indicate dry, open-canopy forest[16,18]. In the Raton sequence (Fig. 2) dispersed-cuticle assemblages from the base of the formation to <1 cm below the K–T boundary show no physiognomic changes that indicate significant change in climate. Although leaf size increased into higher latitudes, drip tips were uncommon, suggesting subhumid forest. At 66° N, vegetation was large-leaved deciduous forest that resulted from the polar light regime[19].

Broad-leaved decidous plants were not diverse in mid-latitude Lancian vegetation (Fig. 2), as is true for modern Southern Hemisphere vegetation; thus we use the Southern Hemisphere ratio between the proportion of entire-margined species (EM) and mean annual temperature[10]. The 20 °C isotherm (megathermal/mesothermal boundary) falls at 50°–53° N, consistent with major floristic differences in megafloras[15] and palynofloras[20]. The latitudinal temperature gradient was ~0.3 °C per degree of latitude (Fig. 3), a gradient also obtained for the North American Campanian[18]. Comparisons of early to late Lancian assemblages in the same areas indicate no significant change in EM and thus no change in temperature.

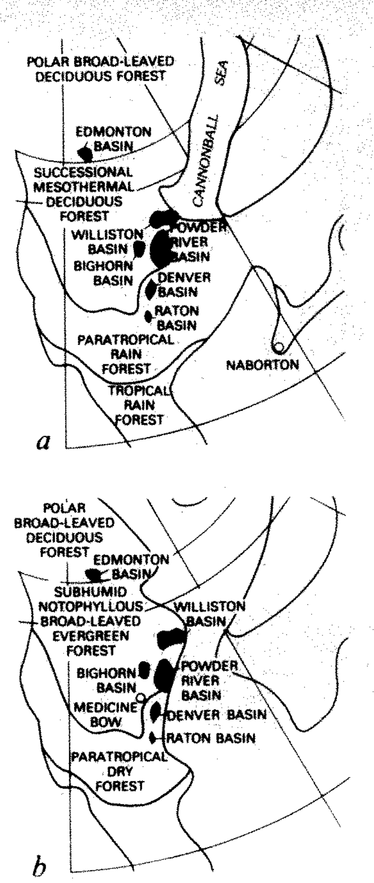

Fig. 1 Maps of the western interior of North America during *a*, the early Palaeocene and *b*, the latest Cretaceous showing major depositional basins, floral assemblages and inferred vegetation. Mesothermal vegetation includes the southern part of polar broad-leaved deciduous forest, subhumid notophyllous broad-leaved evergreen forest and successional mesothermal deciduous forest. Megathermal vegetation includes paratropical dry forest, paratropical rain forest and tropical rain forest (see refs 10, 19). Throughout the Late Cretaceous and early Tertiary the southern margin of polar broad-leaved deciduous forest fell between paleolatitudes 65° and 70° N (refs 18, 19). Continental position adapted from ref. 17); mid-Maestrichtian and early Palaeocene epicontinental seas adapted from ref. 26.

Palaeocene assemblages <3 m above the K–T boundary (Phases 2 and 3) indicate ecological disruption and mass kill. Assemblages of Phase 2, which includes the palynological fern spike[5], are dominated by herbaceous monocots and/or ferns, which persist into Phase 3. Phase 3 assemblages are low diversity and have leaves of early successional morphology[12]. Included are narrow-leaved taxa that typically occurred in disturbed, fluviatile habitats during the Lancian, but during early succession following the K–T boundary opportunistically invaded swamp habitats. Temperature inferences are difficult for such a limited flora, but the large leaf size suggests abundant moisture.

All early Palaeocene assemblages of Phases 4 and 5 have large leaf size with no latitudinal increase. Increase in leaf size over Lancian assemblages from 46° to 56° N indicates increased precipitation, as does an increase in the proportion of drip-tipped species and a change in cuticular physiognomy in the south. In the Raton sequence this change occurs at the K–T boundary[16]. This increase would lead to high-biomass vegetation and high water tables and was possibly the major causative factor in the widespread initiation of peat deposition that marks the boundary in the northern High Plains. Persistence of high precipitation indicates that the climate was pushed into a new, metastable mode. Initiation of megathermal rain forest environments had major biotic consequences[18,21].

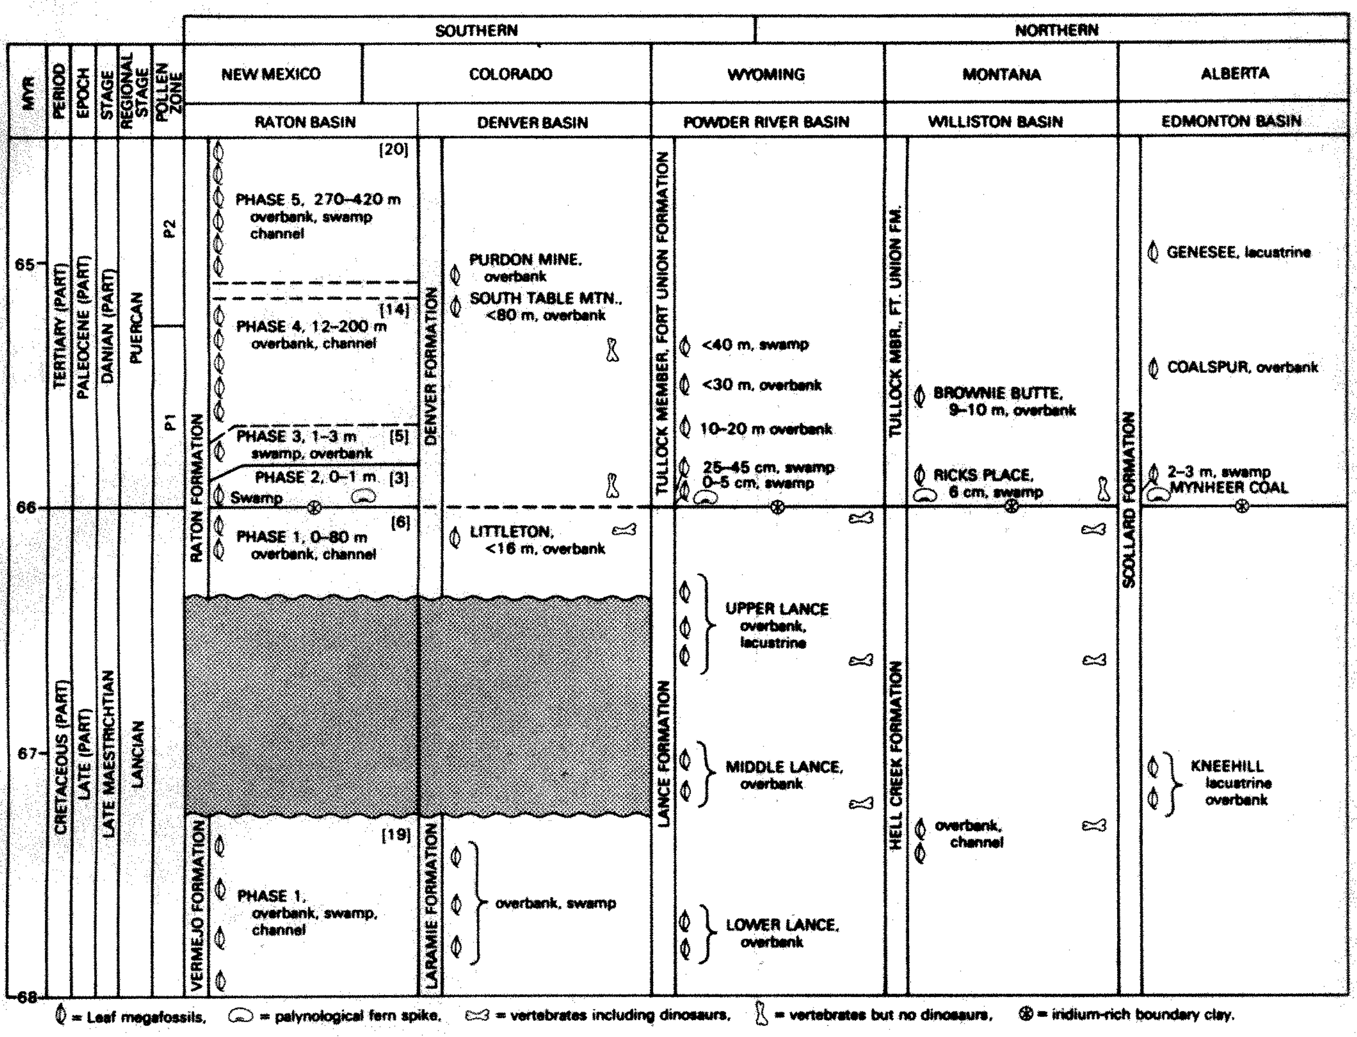

Fig. 2 Stratigraphical and depositional occurrences of some plant megafossil assemblages relative to the Cretaceous-Tertiary boundary in the western interior. Estimates of absolute ages are based on some radiometric and some palaeomagnetic data[34,35]. Palynological data from refs 5, 36–38; stratigraphical data from refs 16, 39 and unpublished data; Physiognomic and floristic data from refs 16, 40–44 and unpublished data. Following some floral symbols are measured or estimated stratigraphical interval from the boundary. Numbers in brackets in the Raton Basin column are numbers of individual localities.

Diversity in Phases 4 and 5 increased over Phases 2 and 3 but was still lower than in Phase 1. Percentages of entire-margined and evergreen species sharply decline northward compared to the Lancian. During the early Palaeocene, megathermal forest extended to 50°–53° N (as in the Lancian) in the western interior but was anomalously bounded on the north by broad-leaved deciduous forest; mesothermal, notophyllous, evergreen forest is unknown. Anomalous deciduousness characterizes most extant mesothermal vegetation of southeastern North America, resulting from prolonged, intense freezes[10]. If such climates characterized the northern High Plains early Palaeocene there would not be a diverse fauna of large ectotherms.

However, occurrence in the northern High Plains of large and presumably ectothermic reptiles (turtles, champsosaurs, and crocodilians[22], some >3 m long; W. S. Bartels, personal communication) indicates that earliest Palaeocene temperatures were, as in the Lancian, mesothermal. The Raton data also indicate the same temperature during the Lancian as during the early Palaeocene, and the megathermal/mesothermal boundary was unchanged. These data make previous temperature estimates[23,24] for the northern high plains early Paleocene, based on deciduousness and low EM, suspect.

Thin leaves, mostly from deciduous plants, typically have toothed margins[12]. Thus if vegetation is anomalously deciduous, a low EM relative to temperature results. This phenomenon is apparent in the western interior early Palaeocene: if the EMs for the leaf assemblages give a valid measure of temperature, the latitudinal temperture gradient from New Mexico to Montana would be 1.2 °C per degree of latitude (Fig. 3). This gradient, which is one-third higher than the present gradient from the southern high plains to Alberta, would produce a mean annual temperature of −2 °C in central Alberta and a polar temperature of −28 °C. Such low temperatures are clearly contradicted by the climatic implications of the Genesee and other northern assemblages[25] and would be unlikely because of the transgressing early Palaeocene Cannonball Sea[26]. Deciduous immigrants in the Denver and elimination of most broad-leaved evergreens in northern Phase 5 assemblages skew the leaf-margin analysis. In Raton Phase 5 vegetation northern deciduous taxa were few and did not affect EM[16].

Oxygen-isotope data[27] suggest a temperature increase from the early into the late Maestrichtian, and analyses of North American Maestrichtian floras[18] parallel marine data. No climatic change can be detected between early and late Lancian assemblages in the late Maestrichtian. Lancian temperature is indistinguishable from early Palaeocene temperature.

Palynological interpretations of the K–T boundary in the western interior suggest little extinction, with most taxa persisting in refugia[5], but are complicated by the facts that (1) palynofloras rarely contain Magnoliidae pollen; and (2) a palynomorph

Numbers in parentheses are based on small samples and may not be reliable. Significant taxa are primarily those numerically common in the samples. Scientific names which are not correct, but for which no alternative has been proposed, are shown in quotation marks. Aff. indicates related taxon.

* A few previous collections were not examined; from taxa listed most physiognomic parameters can be calculated, but not leaf size index.

† NBLEF, notophyllous broad-leaved evergreen forest; PBLDF, polar broad-leaved deciduous forest; PDF, paratropical dry forest; PRF, paratropical rain forest; S, successional (probably mostly shrubby); SMDF, successional mesosthermal deciduous forest; SPLDF, successional polar broad-leaved decidous forest; SPRF, successional paratropical rain forest; TRF, tropical rain forest.

‡ D, dry; M, moist, W, wet; S, subhumid; Mg, megathermal; Ms, mesothermal.

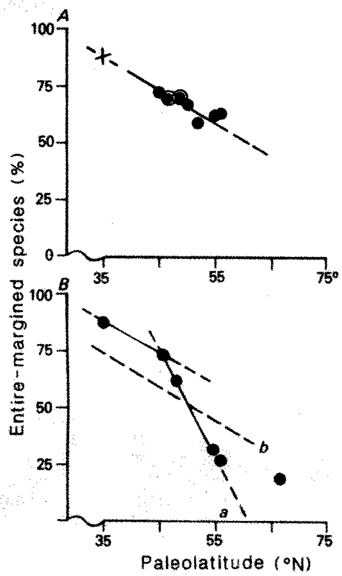

Fig. 3 Least-squares regression analyses of leaf-margin percentages for late Maestrichtian and *B*, early Palaeocene assemblages. In *A*, X denotes early Palaeocene Naborton assemblage and lies along the Maestrichtian regression line. In *B*, line *a* is based on the Raton through eastern Montana assemblages and line *b* is based on all assemblages. Only assemblages of >20 dicot species are included. *A*, $R^2 = 0.55$; *B*, *a*, $R^2 = 0.99$; *b*, $R^2 = 0.24$.

species may be analogous to an extant subgenus, genus or higher-level category[28]. Survival of one species in a previously diverse genus would mask true species-level extinction.

The latitudinal pattern of extinction is that suggested for an 'impact winter'[24]. Most (75%) Raton Lancian leaf species, especially Magnoliidae, are unknown in the early Palaeocene; dispersed cuticles of many of these taxa are found <1 cm below the K-T boundary[16]. Our analyses of the Denver floras indicate similarly high extinction. As at Raton, Denver deciduous taxa had far less extinction than evergreen taxa. In the northern high plains extinction across the K-T boundary was 50-60%[24]. Notable in the early (and later) Palaeocene of the northern High Plains are deciduous taxa that were either uncommon in Lancian mesothermal vegetation or characteristic of polar deciduous forest (for example, trochodendroids and hamamelidaleans). Some evergreens apparently re-invaded from the south. Typically these taxa (for example, *Myrtophyllum*) are the few that occurred in both megathermal and mesothermal vegetation during the Lancian and thus may have survived in the south to re-expand northward temporarily; these taxa are typically rarer in the earliest Palaeocene than in the Lancian and unknown in the late early Palaeocene. Our preliminary analyses of known leaf floras in central Alberta indicate that most (76%) Lancian leaf lineages survived into the early Palaeocene. Extinction was highest among archaic deciduous and evergreen gymnosperms. However, the general pattern in the western interior is extinction of evergreen and survival of deciduous plants. Abilty to enter dormancy was a major factor in survival across the K-T boundary.

In the Raton Basin vegetational change over an estimated 1.5 Myr mimics a successional pattern in diversity (quasisuccession)[16]. This pattern resulted from high extinction in megathermal evergreen vegetation at the K-T boundary. Mesothermal evergreen vegetation also suffered major extinction in the northern high plains, resulting in establishment and persistence of quasisuccessional, low-diversity deciduous forest analogous to successional vegetation in extant mesothermal regions. Polar deciduous forest was disrupted in the earliest Palaeocene but suffered little extinction and was re-established by the late early Palaeocene.

Occupation of the mesothermal region by deciduous forests through most of the Palaeocene[29] indicates that there were no mesothermal refugia; otherwise, evergreens should have rapidly re-occupied this region. Replenishment of evergreens in mesothermal vegetation could then only occur by evolutionary adaptation from an impoverished megathermal flora. Slow replenishment of megathermal vegetation, evidenced by low diversity in Raton Phase 5 assemblages, suggests low survival rate in megathermal refugia.

High survival rate among deciduous versus evergreen plants indicates an event that favoured deciduous plants over evergreens sensitive to low temperature. The simplest explanation is a low-temperature excursion. High survival rate among aquatic ectotherms[30] places major constraints on severity and duration of the temperature excursion. Large aquatic ectotherms might survive a few months of a mean near freezing, but temperatures that would freeze water to a considerable depth, or a long period of inactivity without feeding would certainly be fatal (ref. 31 and J. H. Hutchison, personal communication). Many extant megathermal plants cannot tolerate temperatures <10 °C and most mesothermal broad-leaved evergreens cannot survive a cold-month mean <1 °C (ref. 10). Biological data are consistent with a short period (1-2 months) of a mean temperature near 0 °C. Deciduousness selected by the temperature excursion left a profound imprint on Northern Hemisphere Cenozoic vegetation[29,32]. Rarity of deciduousness in Southern Hemisphere Cenozoic vegetation suggests that the temperature excursion had little effect in the Southern Hemisphere.

The sharpness and magnitude of vegetational and floral changes at the K-T boundary are dramatic. Mass-kill, ecological disruption and climatic change are associated with the event that produced the iridium-rich clay. The clays at various sites must be synchronous: were they of disparate ages, short-term successions, not quasisuccession, would have resulted. Although some[33] have proposed that the event was a marked and prolonged cooling from massive volcanic eruptions, the data from the land biota overall support a brief low-temperature excursion resulting from a bolide impact[1].

Growth and longevity of krill during the first decade of pelagic whaling

A. A. Rosenberg, J. R. Beddington & M. Basson

IIED/IUCN Marine Resources Assessment Group, Imperial College, 48 Prince's Garden, London SW7 1LU, UK

Krill (*Euphausia superba* Dana), the dominant member of the zooplankton community of the Southern Ocean, has been the subject of study for many years. As the main prey species of the baleen whales, several species of seals and many sea bird, fish and cephalopod species, its importance within the ecosystem is clear. It is important for the practicalities of management of the Southern Ocean to estimate the ability of krill to sustain a harvest by man or by its natural predators[1,2]. This estimation requires a knowledge of growth and longevity[3,4], which in krill are the subject of some controversy. Conflicting results have been obtained from krill size composition analysis, which indicates a short lifespan, and age pigment analysis, which indicates a longer life. Here we have analysed eight years of data on krill taken between 1928 and 1938 and have obtained estimates which consistently indicate high growth rates, modulated by a strong seasonal pattern. The cumulative growth through the year is therefore consistent with the studies of age structure using pigment analysis.

In the absence of any method for ageing krill early studies relied on the deduction of estimates of age from information obtained on the length composition of samples[5-11]. The results of these studies indicated a high growth rate, with maximum length being approached within a short life cycle of 2-3 years. Recent work has used the age pigment lipofuscin to determine metabolic age[12,13]. However, these studies suffer from a lack of knowledge of the relationship between metabolic age and real time. They have, to date, only been applied to very small samples of krill. The lipofuscin method, originally developed from studies on insects, has not yet addressed the difficulties of working with an animal like krill which does not have a terminal molt. An unknown proportion of the pigment is lost during ecdysis[12] which may affect the interpretation of results. Despite these problems, these studies indicate a rather longer life cycle with individuals of ages 6-7 being present. The implications for harvesting are that if the shorter lifespan is correct a much larger proportion of krill standing stock may be taken as harvest.

The most extensive time series of length composition samples of Antarctic krill were taken by the British R.R.S. Discovery expeditions which operated from 1926-1951. This sampling period coincided with the first period of major exploitation of the stocks of great whales in the Southern Ocean. We have re-analysed the length composition data on *Euphausia superba* for the period 1928-1938 with two recently developed, simple analytical methods to determine the growth of this species through the period and its expected longevity.

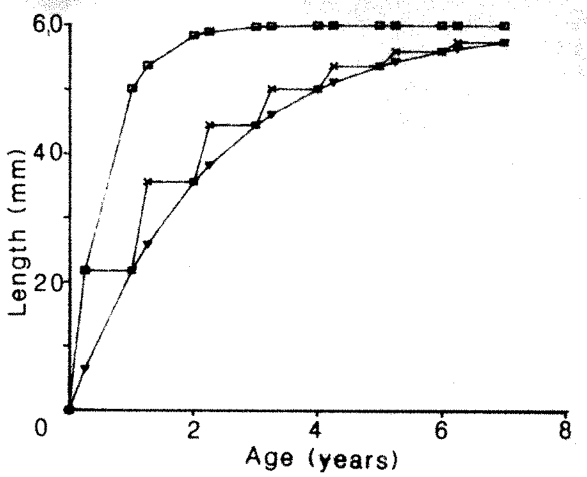

Fig. 1 Von Bertalanffy growth curves with parameters □, $k = 1.8$ (equation 1); ▼, $gk = 0.45$ (equation 2); and ×, the step function for seasonal growth with $k = 1.8$ and $g = 0.25$ (equation 3). In all cases $L_{inf} = 60.0$.

Length composition samples for the period 1928-1938 were taken from the logbooks of the Discovery expeditions and incorporated into a computer database by staff of the Institute of Oceanographic Sciences (Wormley, U.K.) and the Marine Resources Assessment Group of Imperial College (London, U.K.). The population structure of *E. superba* is unknown. Because of this we treated broad geographical regions as the units relevant for analysis. For each year the region containing the most extensive set of samples was used for the estimation of growth rate. We examined the data in two ways: as a standing stock, to provide an average view of the length composition over the year, and to find the monthly change in length composition through the growing season. With a few exceptions the samples were taken between September and May.

We consider growth to be described by the von Bertalanffy curve often used in fisheries biology. That is

$$l_t = L_{inf}\,(1 - e^{-kt}) \qquad (1)$$

where l_t is the length of an animal at age t (where the age of the animal is measured from the time at which it had length zero), L_{inf} is a parameter giving the asymptotic maximum length for the animal and k is a growth constant with units 1/time.

A dominant feature of the Southern Ocean environment is seasonality. There is substantial evidence that growth of many animals virtually ceases during the winter[14,15]. Laboratory experiments on krill indicate that animals may even shrink if starved[16]. To account for such seasonality in samples which average the length composition over the year we modify equation (1) such that

$$l_t = L_{inf}\,(1 - e^{-gkt}) \qquad (2)$$

where g is the proportion of the year in which the animals are growing. We hypothesize that the actual growth of the animal approximately follows a step function given by

$$\begin{aligned} l_t &= L_{inf}\,(1 - e^{-k(t-n(1-g))}) \quad n < t \leq n+g \\ l_t &= l_{n+g} \quad n+g < t < n+1 \end{aligned} \qquad (3)$$

where n is the number of winters the animal has survived. Figure 1 illustrates the growth curves given by equations (1) and (2) and the step function given by equation (3). The monthly length composition data were used to estimate the parameter k in equation (2). The data were the proportion of animals in the total monthly sample in each 5 mm length interval from 5 mm to 65 mm (see Fig. 2, top). To estimate k we write a projection matrix[17], whose elements are a function of the von Bertalanffy equation parameters k and L_{inf}, which takes the length composition at time t to the composition at $t + dt$ where dt is the time between samples. This matrix is analogous to a Leslie population projection matrix. The first sample in a given growth season is projected forward to the sampling times of all subsequent length compositions taken in the same season using the matrix. The

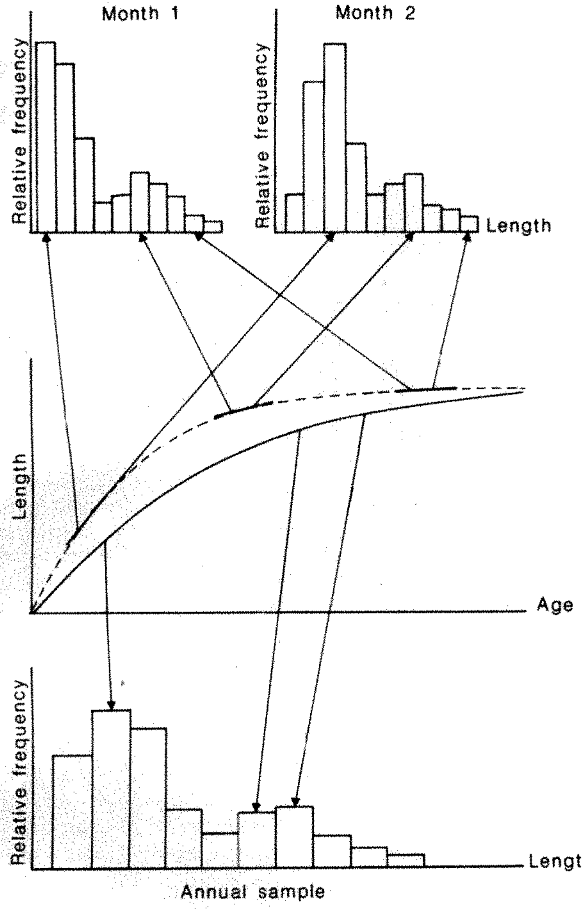

Fig. 2 Schematic representation of growth parameter estimation methods. Dashed line, growth curve for krill during growth season. Arrows indicate movement of individual krill from one population to another. Solid line, length against age for annual sample (age up to 6-7 years). The shape of the dashed line is estimated by examining the length frequency distributions in successive time periods during the growth season, (several months). The parameter *k* which best projects the timecourse of the samples through the season is chosen by least squares. The shape of the solid line is estimated using a method involving a scoring function that determines which parameter combination, *gk*, best match the modes observed in annual length compositions.

estimate of *k* is that value which best matches the predicted to observed length compositions under a least squares criterion (Fig. 2). The value of L_{inf} can be taken as the size of the largest individual observed assuming that the largest individuals in the population are sampled by the gear used. We set L_{inf} to 60 mm for the results reported here. However, our results for the estimation of *k* are insensitive to variations of 5 mm either side of this asssumed value[20].

For the yearly (standing stock) length composition data the parameter estimates are approximately equivalent to the product *gk* in equation (2) since they represent growth averaged over the year, not just within the high growth season. We used a slight technical modification of Shepherd's[18,20] method which scores the modes in the observed length composition based on their predicted position for a given growth curve (Fig. 2). Monte Carlo tests for the two methods indicate their accuracy to be within 10 and 15% of the true value of *k* respectively[20].

The estimated *k* values from the monthly data are quite consistent through the period (Table 1). The average is 1.80. This level of *k* gives a daily growth rate for krill during the fast growth season as 0.148 mm per day. Recent laboratory studies have shown *E. superba* to attain growth rates of around 0.13 mm per day[15,19].

The *k* values for the yearly data (Table 1) again show a high degree of consistency, as with the monthly data. The estimated yearly *k* values are approximately 1/4 of those for the high growth season indicating that maximal growth occurs over approximately three months beginning in the early spring with the seasonal increase in primary production. Such strong seasonality in growth has been reported for other types of animals in Antarctic waters[14]. The strong seasonality in krill growth implies that modes in the length composition for each age group will be most distinct early in the austral spring and samples taken then be most valuable for monitoring growth rate.

Table 1 Growth parameter estimates for krill, *Euphausia superba*, sampled during the Discovery investigations

Split year (June-May)	Summer season growth k*	Summer season growth mm per day†	Yearly growth gk‡	Yearly growth g	Area	n
1928	2.18	0.179	0.43	0.20	Scotia Sea	751
1931	1.79	0.147	0.47	0.26	Scotia-Weddell	994
1934	1.42	0.117	0.27	0.19	Scotia-Weddell	594
1935	1.96	0.161	0.46	0.23	Australian	4,624
1936	1.28	0.105	0.47	0.37	Scotia-Weddell	10,208
1937	2.09	0.172	0.34	0.16	Australian	5,526
1938	1.89	0.155	0.47	0.25	Indian	6,148

Data are for split years over broad geographic regions in the Southern Ocean. Summer season growth refers to the von Bertalanffy parameter *k* estimated from a series of length frequency samples taken in a single growth season. Yearly growth is the estimated parameter combination, *k* times *g*, which represents the average growth over the entire year, not just the growing season. The number (*n*) of krill measured in each split year's samples which were used to estimate the length composition is given.

* Estimated from monthly length compositions—projection matrix.

† At a length of 30 mm growth rate in millimeters per day.

‡ Estimated from yearly length compositions—modal analysis.

Conflicting results concerning the possible lifespan of krill are now interpretable. Growth rates are quite high for this species as would be consistent with a short (2-3 yr) life cycle. However, since the animals only grow through a few months of the year, the effective rate over the entire year is more consistent with a 6-7 yr lifespan as estimated from the age pigment data. Put another way, the average effective growth rate estimated (represented by the step function in Fig. 1) means that it will take a minimum of 6-7 yrs for a krill to approach a length of 60 mm.

An important question is whether the growth of krill has changed in recent years in response to low levels of their baleen whale predators. Our results indicate growth to be quite variable between years and areas, but comparable analyses to our work on the Discovery data have not been performed on recent samples. The recently reported presence of 6-7 year old krill is not inconsistent with length compositions sampled during the first decade of pelagic whaling and so do not imply an increase in krill longevity in response to decreased predation.

This work was supported by the Natural Environment Research Council. A.A.R. was supported by a NATO Postdoctoral Fellowship. We thank Mr A. de C. Baker, Drs I. Everson & J. G. Shepherd for helpful advice and for help in setting up the database. The IIED/IUCN Marine Resources Assessment Group acknowledge support from IUCN and the World Wildlife Fund.

Ocular dominance shift in kitten visual cortex caused by imbalance in retinal electrical activity

Barbara Chapman, Michael D. Jacobson, Holger O. Reiter & Michael P. Stryker

Division of Neurosciences and Department of Physiology,
University of California, San Francisco, California 94143, USA

Monocular lid suture during the sensitive period early in the life of a kitten disrupts normal development of inputs from the two eyes to the visual cortex, causing a decrease in the fraction of cortical cells responding to the deprived eye[1]. Such an ocular dominance shift has been assumed to depend on patterned visual experience, because no change in cortical physiology is produced by inequalities between the two eyes in retinal illumination[2] or temporally modulated diffuse light stimulation[3,4]. A higher-level process, involving gating signals from areas outside striate cortex, has been proposed to ensure that sustained changes in synaptic efficacy occur only in response to behaviourally significant visual inputs[5]. To test whether such a process is necessary for ocular dominance plasticity, we treated 4-week-old kittens with visual deprivation and monocular tetrodotoxin (TTX) injections to create an imbalance in the electrical activities of the two retinas in the absence of patterned vision. After 1 week of treatment we determined the ocular dominance distribution of single units in primary visual cortex. In all kittens studied, a significant ocular dominance shift was found. In addition to this physiological change, there was an anatomical change in the lateral geniculate nucleus, where cells were larger in laminae receiving input from the more active eye. Our results indicate that patterned vision is not necessary for visual cortical plasticity, and that an imbalance in spontaneous retinal activity alone can produce a significant ocular dominance shift.

For this study 11 28–34-day-old kittens received intravitreal injections of 5 mM TTX in one eye to block ganglion-cell activity in that eye[6]. Patterned visual input to the other eye was eliminated by suturing the eyelid. Six of the kittens (TTX/lid-suture group) were kept in a normal light cycle, and thus experienced no activity in one eye and diffuse, temporally modulated light in the other. The remaining five kittens (TTX/dark group) were kept in the dark, experiencing no activity in one eye and only spontaneous activity in the other eye. The retinal action potential blockade was maintained for 1 week by repeating the TTX injections. The lid of the injected eye was then sutured and the animals remained or were placed in the dark to prevent vision during recovery of retinal activity. Twenty-four to 48 hours after the retinal blockade began to wear off, the kittens were prepared for electrophysiological recording as described elsewhere[7].

To demonstrate that normal activity had returned to the previously blocked eye, 5–13 single units with central receptive fields (within 15° of the area centralis) were recorded in the lateral geniculate nucleus (LGN) contralateral to the injected eye. In addition, multi-unit responses were assessed every 100 μm through laminae A and A1. No difference in responsiveness was detected between cells driven by the two eyes (see Figs 1, 2), nor between multi-unit recordings in laminae responsive to the two eyes. Briskly responsive ON- and OFF-centre and sustained and transient units were recorded in both laminae.

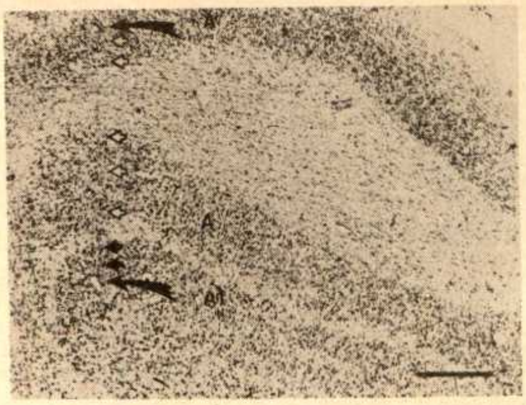

Fig. 1 Coronal Nissl-stained section through an LGN contralateral to the TTX-injected eye. The section shown is 2.88 mm caudal to the rostral pole of the LGN. An electrode track is shown with electrolytic marking lesions indicated by curved arrows. Filled arrows, locations of single units responding to the untreated ipsilateral eye; open arrows, single units responding to the previously blocked contralateral eye. Receptive fields of the units indicated by the top two arrows were at elevation 30°, azimuth 9°; those of the units indicated by the lower five arrows ranged between elevation 6°, azimuth 4° and elevation 4°, azimuth 2°. Scale bar, 0.5 mm.

To determine whether an ocular dominance shift had occurred, we studied cortical area 17 contralateral to the injected eye. This hemisphere was chosen because normal kittens show an ocular dominance bias toward the contralateral eye[6]; thus if recording was in the hemisphere ipsilateral to the TTX-treated eye, an apparent shift in ocular dominance towards the more active eye could be caused, at least in part, by this bias. In the hemisphere contralateral to the injected eye, however, an ocular dominance distribution favouring the more active (ipsilateral) eye must be caused by the effects of deprivation. Horizontal electrode penetrations were used to sample cells across, rather than down, ocular dominance columns; each penetration was long enough to pass through several columns. The intended sample size was 30 cells per animal. Receptive fields of all units studied were within 15° of the area centralis. Ocular dominance was determined for each visually responsive unit using the standard seven-point scale[8]. For both conditions, TTX/lid suture and TTX/dark, ocular dominance histograms were significantly shifted toward the more active, ipsilateral eye (Fig. 3*b*, *c*). These data contrast with histograms from normal kittens of the same age, which show a slight bias in favour of the contralateral eye (Fig. 3*a*), as well as with the more strongly shifted histogram from conventional monocularly lid-sutured kittens (Fig. 3*d*). The degree of shift in each kitten, estimated by a scalar index, indicates that our two groups are significantly different from both normal and conventionally monocularly deprived animals (Mann–Whitney *U* test, $P<0.01$), but that the results in the TTX/lid-suture and TTX/dark groups are not significantly different (Mann–Whitney *U* test, $P>0.05$) (Fig. 4*a*).

In 7 of the original 11 kittens, cross-sectional areas of cells in the LGN were measured in Nissl-stained sections. (LGN cell sizes are known to be smaller in the laminae responding to the deprived eye in kittens with monocular lid suture[1,9] or monocular TTX blockade[10].) As expected, cell sizes were smaller in laminae responding to the TTX-treated eye in both TTX/lid-suture and TTX/dark animals. These morphological results, like the physiological ones, are intermediate between those from normal and monocularly deprived animals (Fig. 4*b*).

Although unlikely, the changes in cortical physiology observed could have been caused by damage to the TTX-treated eye that was not detected in our geniculate recordings, rather

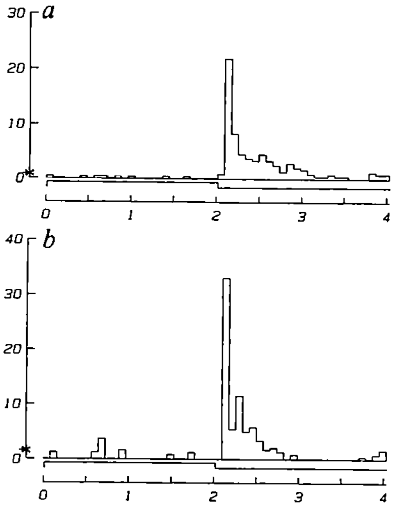

Fig 2 Post-stimulus histograms showing examples of the flash response of single OFF-centre units driven by the untreated ipsilateral eye (*a*) and by the previously blocked contralateral eye (*b*) in the same LGN Stimulus intensity was one log unit above threshold *y*-axis, spikes per s, *x*-axis s Asterisk, level of spontaneous activity, stimulus time course, line above the *x*-axis (ON, up, OFF, down)

than by the activity blockade If such toxicity was responsible for the ocular dominance shifts, the effects should be permanent If, however, differential activity were responsible, then the shifts should be reversible, as are those produced by conventional monocular deprivation in kittens of the same age[11] To test the reversibility of our treatment, two additional kittens were studied These kittens experienced 1 week of the TTX/lid-suture treatment starting at 28 or 32 days old After the TTX blockade wore off, the kittens remained in a normal light cycle for 9 or 11 days with the sutured eyelid remaining closed Thus, these kittens experienced a week of no activity in the TTX-treated eye combined with diffuse light vision through a closed lid in the other eye, followed by a period of conventional monocular deprivation with patterned vision in the previously TTX-treated eye The first week of treatment presumably produced an ocular dominance shift toward the lid-sutured eye, as occurred in TTX/lid-suture animals If TTX injections did not cause permanent damage, this shift should have been reversed during the period of monocular deprivation, resulting in a cortical bias in favour of the eye that had been blocked during the first part of the treatment and had experienced patterned vision during the second part Single-unit recordings from area 17 of the two kittens showed that such a reversal had occurred Ocular dominance histograms from both kittens were strongly shifted toward the eye that was first blocked and then had patterned vision The degree of shift in these kittens (contralateral bias indices 86 and 99, see Fig 4 legend) was comparable to that seen in conventional reverse lid-sutured kittens of the same age[11] Thus TTX injections do not cause lasting damage to the ability of the treated eye to compete for cortical dominance

The similarity of three of the present findings to those from conventional monocular deprivation experiments indicates that the ocular dominance shifts seen in TTX/lid-suture and TTX/dark animals were caused by the differences between activities of the two eyes, rather than by damage to the retinal ganglion cells of the injected eye (1) LGN responses to stimulation of the two eyes were equally good even in the most shifted animals in which few or no cortical cells responded to the injected eye (2) LGN cell sizes were smaller in laminae responding to the injected eye (3) The ocular dominance shifts produced were readily reversible

We draw three conclusions from the results of these experiments First, the significant changes in ocular dominance in both TTX/lid-suture and TTX/dark animals show that patterned vision is not necessary to produce changes in cortical physiology Second, the results from the TTX/dark group indicate that an imbalance in spontaneous activity alone is enough to cause an ocular dominance shift Third, the similar results produced by TTX/dark and TTX/lid-suture treatments suggest that the vision that occurs through a closed eyelid has little additional effect on ocular dominance

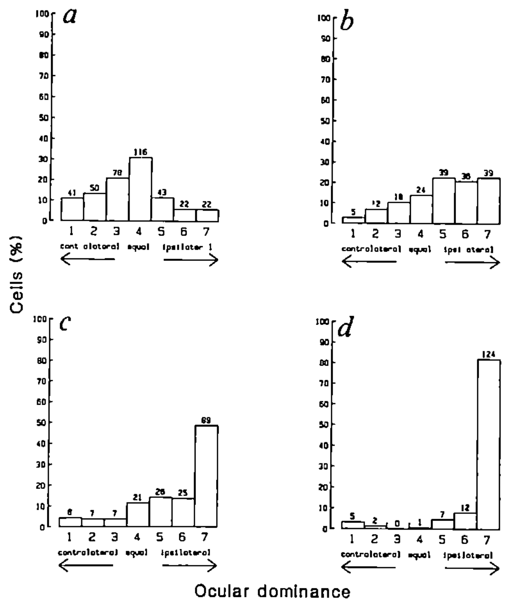

Fig 3 Ocular dominance histograms[8] compiled from single unit responses in area 17 An ocular dominance of 1 indicates a cell driven only by the contralateral eye, 7 a cell driven only by the ipsilateral eye, and 4 a cell driven equally by the two eyes In each deprivation condition, the contralateral eye is less active *a*, 372 visually responsive units from six normal kittens, 36-51 days old 26 visually unresponsive units recorded[6] *b*, 173 visually responsive units from five TTX/dark kittens, 37-44 days old 12 visually unresponsive units recorded *c*, 183 visually responsive units from six TTX/lid-suture kittens, 36-40 days old 19 visually unresponsive units recorded *d*, 151 units from four kittens monocularly deprived by lid suture for 3 5-6 days, followed by 0-2 days recovery in darkness, 29-34 days old[9,15 16]

It is generally believed that cortical plasticity is dependent on cortical cells being driven by their geniculate inputs Silencing all cortical activity through intra-cortical TTX injections prevents ocular dominance shifts in monocularly deprived animals[12] Because geniculate[13] and cortical[14] spontaneous activities are dependent on levels of spontaneous activity in the retina, spontaneous activity must drive cortical cells, however weakly Thus the present results are consistent with a model of plasticity requiring that cortical cells be driven

Our conclusion that ocular dominance shifts can be produced in the absence of patterned vision does not necessarily refute the central gating hypothesis[5] Although shifts in our animals did occur without behaviourally significant visual input to either eye, these shifts were not as large as those seen in conventionally monocularly deprived animals[9,15,16], although the differences in retinal activities were extreme Perhaps the central gate is always slightly open, allowing some degree of shift to occur Behaviourally significant information could further open the gate, causing the larger ocular dominance shifts seen in conventionally monocularly deprived animals We do not know why ocular dominance shifts were produced by the present conditions but not by other rearing conditions with different inputs to the two eyes in the absence of patterned vision[2-4] The actual retinal activities produced by any of these rearing conditions are, however, unknown (except that TTX does block all activity[6]) Therefore, either a large quantitative difference or some temporally modulated qualitative difference between the

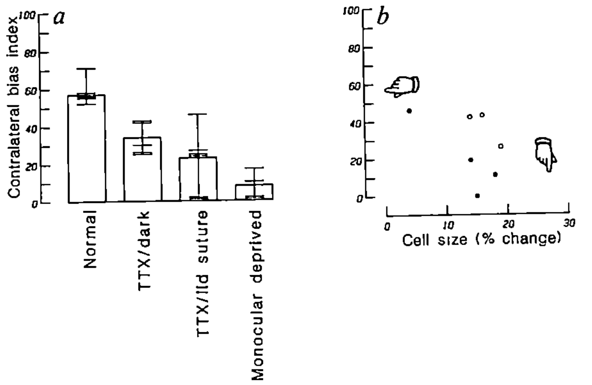

Fig. 4 *a*, Contralateral bias indices showing the range of findings among individual animals from Fig 3 *b*, Scatter plot of per cent change in geniculate cell size versus contralateral bias index *a*, The index provides a single number reflecting the degree of ocular dominance shift for each animal The index is calculated according to the equation

$$100[(1-7)+2/3(2-6)+1/3(3-5)+n]/2n$$

Italicized numbers, number of units in each ocular dominance group, *n*, total number of visually responsive units This index is 100 if all cells are driven exclusively by the contralateral eye and 0 if all cells are driven exclusively by the ipsilateral eye The greater variability among TTX/lid-suture animals is unexplained, it may be caused by differences among the animals of this group in the amount of diffuse-light stimulation of the retina of their sutured eyes *b*, Cells (75 per lamina) were measured in both LGNs of each animal Measurements were made in the latero-medial middle third of coronal sections taken ~2 5 mm caudal to the rostral pole of the nucleus (the area corresponding to the central 5-10° of the visual field)[26] All cell bodies with visible nucleoli were traced in the camera lucida under ×63 or ×100 oil-immersion objectives at final magnifications of ×1,160-1,840 The areas of these tracings were then measured using a Summagraphics Bitpad Planimeter The standard errors ranged from 4 to 6% of the mean for individual laminae Per cent change was calculated as 1−∑ mean cell sizes from laminae responding to the injected eye−∑ mean cell sizes from laminae responding to the more active eye Open circles, data from TTX/lid-suture animals, filled circles, data from TTX/dark animals Upper finger, region of data from normal animals[6], lower finger, region of data from monocularly deprived animals[9] The spread of these control data along the ordinate is shown in *a*, the spread along the abscissa is ~4% for normal animals and 7% for monocularly deprived animals[9] Although there is no strong correlation between the change in cell size and the degree of ocular dominance shift in our animals, the extents of both morphological and physiological changes are intermediate between data from normal and conventional monocularly deprived animals The morphological results for TTX/dark animals (average percentage change = 16) are very similar to those previously reported for older TTX/dark kittens (average percentage change = 17)[10]

activities of the two retinas may be necessary to produce ocular dominance shifts

Our present finding that imbalances in spontaneous activity alone can cause changes in connections to cortical cells, together with earlier work on the effects of spontaneous activity blockade on the development of ocular dominance columns[6,17], is consistent with the hypothesis that spontaneous electrical activity plays a part in the normal fetal development of the visual system[18] Activity-dependent rearrangements of ocular dominance columns, which occur postnatally in the cat[19], begin 3-6 weeks prenatally in the monkey[20,21] If the development of ocular dominance columns follows similar principles in the two species[22], it is not surprising that spontaneous activity plays this part in the cat because in the monkey *in utero*, vision is occluded, and the only possible electrical activity is spontaneous Observations that retinogeniculate axons make functionally effective binocular connections prenatally[23], some of which are lost before birth[23,24], suggest that spontaneous activity is also involved in the refinement of these connections[24,25]

Intracellular calcium ions decrease the affinity of the GABA receptor

Inoue, M., Oomura, Y., Yakushiji, T. & Akaike, N.*

Department of Physiology, Faculty of Medicine,
Kyushu University 60, Fukuoka 812, Japan

Intracellular free Ca^{2+} ($[Ca^{2+}]_i$) plays a crucial role in the transduction of extracellular signals[1] It has been implicated in the modulation of light sensitivity in *Limulus* photoreceptors[2] and in the efficacy of synaptic transmission[3-5]; calcium ion fluxes are also involved in the postsynaptic facilitation of nicotinic transmission seen in sympathetic ganglia, and in activation of the acetylcholine (ACh) receptor[6,7] $[Ca^{2+}]_i$ is also a second messenger for many biologically active substances[8]. We recorded neuronal activities of sensory neurones from the bullfrog (*Rana catesbiana*), using the suction pipette method[9] and a 'concentration clamp' technique[10] to apply γ-aminobutyric acid (GABA) to the cell. We report the first evidence that $[Ca^{2+}]_i$ suppresses the GABA-activated Cl^- conductance, by decreasing the apparent affinity of the GABA receptor.

Sensory neurones were isolated from dorsal root ganglia by both mechanical dissection and enzymatic digestion in normal Ringer solution containing 0 3% collagenase and 0 05% trypsin at 37 °C for 15 min The isolated cells were maintained in a solution containing equal parts of Ringer and Eagle's minimum essential medium at room temperature (~22 °C) The concentration clamp technique enables complete exchange of the external solution around the cell to occur within a few ms (ref 10) K^+ and Na^+ in both internal and external solutions were replaced with equimolar Cs^+ and Tris, respectively, unless otherwise stated All experiments were performed at room temperature The data have been analysed statistically using Student's *t*-test

Under current clamp conditions, rapid application of GABA (10^{-5} M) in the absence of external Ca^{2+} evoked a large depolarization, and a relatively stable plateau was reached within 2 sec (Fig 1a) This response is mediated through an increase in Cl^- conductance[11] When the application of GABA was preceded by a series of Na^+ spikes (Fig 1b), no effect on the GABA response was apparent However, elicitation of a single Ca^{2+} spike in medium containing Ca^{2+} markedly reduced

---

* To whom correspondence should be addressed

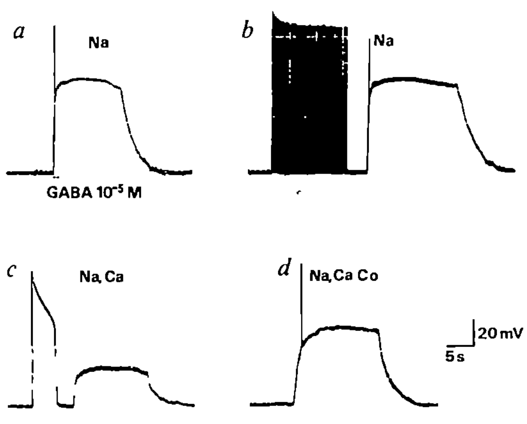

Fig. 1 Effects of Ca^{2+} spike and Na^+ spikes on the GABA-induced depolarization. *a*, 10^{-5} M GABA depolarized the membrane by 75 mV in Na^+ solution (in mM) NaCl 83, $MgCl_2$ 5, TEA-Cl 25, CsCl 2 and glucose 5. The membrane potential was held at −80 mV. *b*, The preceding 50 Na^+ spikes elicited by depolarizing pulses at a frequency of 3.3 Hz had little influence on the 10^{-5} M GABA response (74 mV) in an external Na^+ solution. *c*, Marked suppression of 10^{-5} M GABA response after a 4.3 s duration Ca^{2+} spike in a Na^+ and Ca^{2+} external solution where 2 mM $CaCl_2$ replaced 5 mM $MgCl_2$ and 6 mM NaCl was added to equalize osmolarities, depolarization of 32 mV. *d*, With suppression of the Ca^{2+} spike by adding 4 mM $CoCl_2$ to the Na^+ and Ca^{2+} external solution, 10^{-5} M GABA produced a depolarization of 62 mV which was slightly smaller than the control, probably due to Co^{2+} interference. GABA equilibrium potential of 4 mV agreed well with the theoretical value estimated from the ionic activities of Cl^- in the external and internal solutions. This result suggests that the internal perfusion was complete. The ionic compositions of the standard solutions were (mM) internal, CsCl 95, (TEA-Cl) 25, Cs-aspartate 10, 0.5 EGTA-Ca buffer ($[Ca^{2+}]_i = 3\times10^{-8}$ M) and pH 7.2, external, Tris-Cl 89, TEA-Cl 25, CsCl 2, $CaCl_2$ 2, glucose 5 and pH 7.4. The pH of all solutions was adjusted with Tris and HEPES buffers.

the subsequent response to GABA (Fig. 1c). This inhibitory effect was not simply due to the presence of Ca^{2+} in the external perfusate, since it could be reversed by adding Co^{2+}, which blocks the voltage-dependent Ca^{2+} current (I_{Ca})[12] (Fig. 1d).

Reduction of the GABA response by the Ca^{2+} influx was quantified in Na^+-, K^+-free external solution containing 2 mM Ca^{2+}. Cells were voltage clamped to a holding potential of −50 mV and I_{Ca} was evoked by 50 mV depolarizing command pulses of varying duration. As can be seen in Fig. 2a, the GABA responses were suppressed to a greater extent when the Ca^{2+} influx was increased. A typical relationship between the total amount of I_{Ca} ($\int I_{Ca}$) and the GABA-induced peak response is illustrated in the lower graph of Fig. 2a. It is evident that I_{Cl} in this cell is maximally inhibited when the Ca^{2+} influx exceeds 80 pC. The degree of this I_{Ca}-mediated suppression of I_{Cl} depended on the chelating potency of the internal solution used. When cells were perfused with a solution containing 2.5 mM EGTA, the subsequent response to 10^{-5} M GABA was reduced to 75% ($n = 15$) of control by the preceding 100 ms I_{Ca}, whereas in neurones perfused with 0.5 mM EGTA-Ca^{2+} buffer ($[Ca^{2+}]_i \simeq 3\times10^{-8}$ M), the I_{Cl} was reduced to 50% ($n = 14$) ($p < 0.01$).

An increase of $[Ca^{2+}]_i$ facilitates the onset of depolarization in response to ACh in the frog endplate[13]. In the present study, a similar phenomenon was observed when the time interval between I_{Ca} and the GABA response was short (10 ms as shown in Fig. 2b). In this case, the GABA response reached a maximal value within 250 ms and thereafter I_{Cl} decreased gradually, whereas in the control it continued to rise. However, this acceleration of the GABA-response decay by I_{Ca} was inversely related to the time interval between I_{Ca} and GABA application and was not detectable with an interval of 600 ms, indicating that this facilitated desensitization after an I_{Ca} is only 'apparent'. This phenomenon could be accounted for by the time-dependent activation of the suppressive mechanism triggered by an increase in $[Ca^{2+}]_i$. Figure 2 shows that following I_{Ca}, full inhibition was only achieved after a few hundred milliseconds. The lower graph in Fig. 2b illustrates that recovery from the Ca^{2+}-mediated inhibition occurs within a few tens of seconds. It is not certain whether this time course is one of a change in $[Ca^{2+}]_i$ after I_{Ca} or release of Ca^{2+} from the receptive sites of GABA receptor complexes or a combination of both. In experiments with Ca^{2+} indicator dyes, increases in $[Ca^{2+}]_i$ are reported to last for over 10 s after 1 s I_{Ca} under voltage clamp conditions in sympathetic neurones[14]. These data, however, should not be directly compared with our results, because we recorded neuronal activity with a suction electrode.

It is probable that by dialysis, we removed the soluble cytoplasmic constituents that are important for physiological Ca^{2+} sequestration. However, this disadvantage is not expected to be significant in Ca^{2+} buffering, because in our experiments, cells were perfused with EGTA-containing solutions.

It has been reported that ACh receptor/Cl^- channel complexes in *Aplysia* neurones are inactivated by intracellular Ca^{2+} binding to the receptor complexes[15]. However, Ca^{2+}-mediated inhibition of the Cl^- response in this preparation did not depend on the concentration of ACh, a result which markedly differs from ours. As shown in Fig. 3, the GABA-activated I_{Cl} was inhibited in a competitive manner by I_{Ca}. The degree of this suppression did not depend on membrane potential (which ranged from −40 to −100 mV), although the Ca^{2+}-dependent Cl^- or K^+ conductance[16,17] is markedly voltage-dependent,

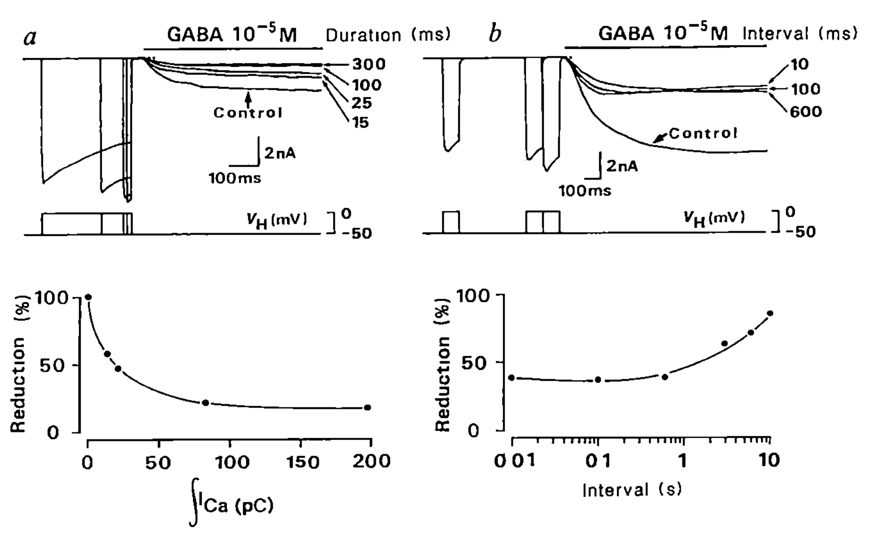

Fig. 2 Suppressing action of I_{Ca} on the GABA-activated I_{Cl}. *a*, Top, actual records of 10^{-5} M GABA-gated I_{Cl}, with and without a preceding I_{Ca} elicited by the depolarizing pulse from the holding potential (V_H) of −50 mV to 0 mV for various durations (15, 25, 100 and 300 ms). The leakage and capacitative currents associated with the ionic currents were subtracted during the experiments by adding the current responses to equal but opposite voltage steps using a signal averager. Bottom, relationship between GABA-gated I_{Cl} and level of voltage-dependent Ca influx (pC). The suppression of GABA-gated I_{Cl} reached a plateau with increasing amounts of I_{Ca}. *b*, Top, actual records of 10^{-5} M GABA-gated I_{Cl} elicited at various intervals after I_{Ca}. Note that the rising phase of I_{Cl} was slow and 'desensitization' became obscure with increasingly large intervals. Bottom, suppression of GABA responses plotted against the interval between the I_{Ca} and GABA responses.

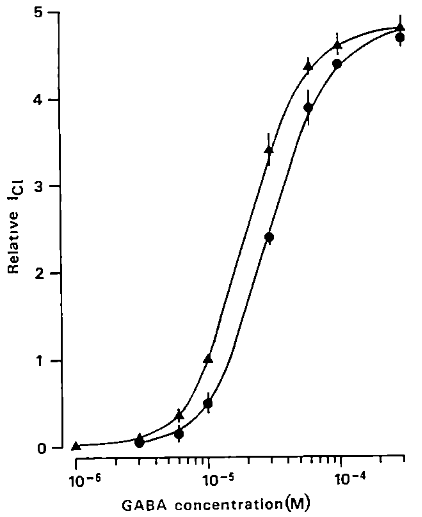

Fig 3 Effect of 100 ms I_{Ca} on the GABA dose-response curve The control dose-response curve (▲) was made by averaging 8 cases, yielding a good fit to the theoretical expression assuming a Hill number of 2 and K_a of 2×10^{-5} M, corresponding to the concentration of GABA producing a half-maximum response When each GABA response was preceded by a 100 ms I_{Ca} (●), more than 5 cases at each concentration were averaged and the data points fell on the line assuming a Hill number of 2 and K_a of 3×10^{-5} M Each data point represents mean ±s e

These results suggest that suppression of the GABA response is related to a decrease in the affinity of the GABA receptor for its agonist We cannot exclude, however, other possibilities such as changes in channel gating kinetics

The experiments reported here clearly demonstrate that a preceding I_{Ca} markedly suppresses the GABA-activated I_{Cl}, and the inhibitory effects are influenced by the EGTA concentration in the internal solution Therefore, it is reasonable to assume that this suppression may be due to an increase in $[Ca^{2+}]_i$ subsequent to the influx of Ca^{2+} However, I_{Ca} could still inhibit the GABA responses in cells perfused with an internal solution containing up to 2 5 mM EGTA These observations suggest that inhibition of the GABA-activated I_{Cl} by Ca^{2+} might occur at a site that EGTA can not gain access to, as in Ca^{2+}-dependent K^+ conductance in smooth muscle[18]

Biochemical studies[17,18] have revealed that various endogenous substances that reduce the binding of GABA are present in the synaptic membranes of the mammalian central nervous system The relationship between Ca^{2+}-mediated inhibition and these substances is currently under investigation The suppression of GABA sensitivity by $[Ca^{2+}]_i$ may be of great importance in phenomena such as epileptogenesis, where the significant Ca^{2+} entry associated with paroxysmal depolarization shifts, may reduce the effectiveness of recurrent inhibition and therefore both prolong burst discharge and enhance the synchronization of firing To our knowledge, this is the first demonstration that $[Ca^{2+}]_i$ rapidly (within a hundred ms) controls the apparent affinity of the GABA receptor

The t(8; 14) chromosomal translocation occurring in B-cell malignancies results from mistakes in V–D–J joining

Frank G. Haluska, Sheldon Finver, Yoshihide Tsujimoto & Carlo M. Croce

The Wistar Institute, 3601 Spruce Street, Philadelphia,
Pennsylvania 19104, USA

The reciprocal chromosome translocation, t(8; 14), involving the heavy chain locus on chromosome 14 (refs 1, 2) and the c-*myc* oncogene on chromosome 8 (refs 3–5) is a characteristic of the B-cell malignancies Burkitt's lymphoma[6] and acute lymphoblastic leukaemia (ALL)[7] We have cloned and sequenced the t(8; 14) breakpoints of an African Burkitt's lymphoma cell line, P3HR–1, and a pre-B cell ALL cell line, 380 (ref 8). In each case the region of chromosome 8 involved has recombined with a J_H region on chromosome 14 The two sites of breakage on chromosome 8 lie within 70 base pairs (bp) of one another. At each joining site, sequences homologous to the signal sequences thought to be recognized by the V–D–J recombinase[9] were identified, as were N regions[9]. In B-cell chronic lymphocytic leukaemias (B-CLL) carrying the t(11; 14) chromosome translocation[10] and in follicular lymphomas carrying the t(14; 18) translocation[11], the V–D–J recombinase is implicated in the mechanism of chromosomal translocations[11]. We speculate that the same enzymatic mechanism is responsible for the t(8; 14) translocations in African Burkitt's lymphoma and pre-B cell ALL.

We have previously described[8] the establishment of a cell line (380) from a patient with a pre-B-ALL (L2 in the French-American-British classification) carrying the t(8, 14) and t(14, 18) translocations Using probes specific to the C_μ region we were able to show that both translocations involve the heavy chain locus, and to clone the breakpoint for the t(8, 14) translocation, which we denoted λ380j9 (ref 12, and Fig 1) To establish which sequences from λ380j9 derive from chromosome 8, we subcloned the 5′ most *Sst*I fragment (p380j9 0 8SS), and used it to probe a Southern blot of DNA from rodent × human somatic cell hybrids containing only chromosomes 8, 14 or the $14q^+$ chromosome from the African Burkitt's lymphoma cell line P3HR-1 (Fig 2*a*) Hybridization occurred only in lanes containing DNA of human chromosome 8, or of the P3HR-1 $14q^+$ chromosome Hence this sequence derives solely from chromosome 8, and this portion of chromosome 8 is translocated to chromosome 14 in P3HR-1

Using this chromosome 8 probe, we screened DNAs from normal and neoplastic tissues in order to detect rearrangements following translocations (Fig 2*b*) Rearrangement was detected in the *Bam*H1 digest of P3HR-1 DNA, as well as the *Hin*dIII digest of Daudi African Burkitt's lymphoma DNA These results indicate that the breakpoints in the 380 and P3HR-1 cell lines lie within the same *Bam*H1 fragment, while the Daudi breakpoint lies on a *Hin*dIII fragment nearby

We attempted to clone the chromosome breakpoints in these cell lines, and to compare them to the 380 breakpoint clone (ref

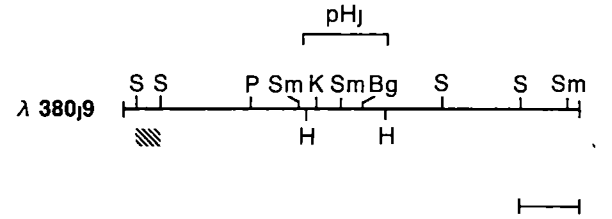

Fig 1 Restriction map of the 14q$^+$ breakpoint clone from the 380 B-ALL cell line, λ380j9 The region of the clone homologous to the joining segment probe pHj (ref 12) is designated by a bracket The hatched box denotes the *Sst*I fragment subcloned as probe p380j9 0 8SS Indicated restriction sites are S, *Sst*I, P, *Pst*I, Sm, *Sma*I, H, *Hin*dIII, K, *Kpn*I and Bg, *Bgl*II Scale bar 2 kb

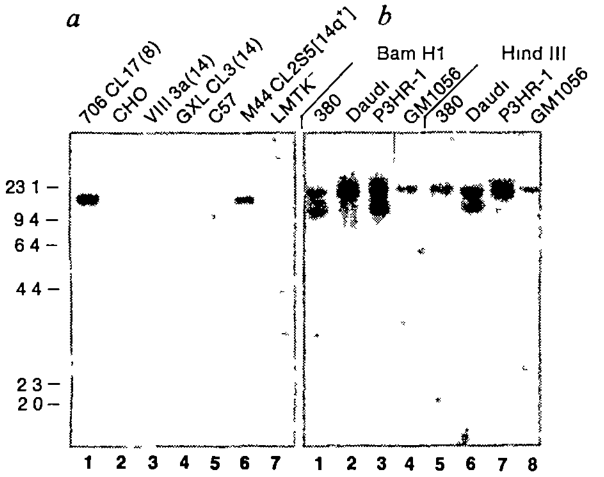

Fig 2 *a*, Southern blot hybridization of *Hin*dIII digested DNAs from human × rodent somatic cell hybrids containing only human chromasome 8, 14 or the P3HR-1 14q$^+$, probed with the p380j9 0 8SS probe Lane 1, 706 Cl 17, a hybrid between a normal human lymphoblast and a Chinese hamster ovary (CHO) fibroblast containing human chromosome 8 but not 14, lane 2, CHO control, lane 3, GM 637×C57 VIII 3a, a hybrid between a simian virus 40-transformed human fibroblast and a mouse parent, containing human chromosome 14 but not 8, lane 4, GM 119×LMTK$^-$ GXL C13, a hybrid between a human fibroblast and mouse LMTK$^-$, also containing human 14 but not 8, lane 5, C56 control, lane 6, P3HR-1×LMTK$^-$ M44 Cl 2S5, a hybrid containing only the 14q$^+$ chromosome from the African Burkitt's lymphoma cell line P3HR-1, lane 7, LMTK$^-$ control *b* Hybridization of 380, Daudi, P3HR-1 and GM 1056 genomic DNAs, with the p380j9 0 8SS probe DNAs were digested with *Bam*HI (lanes 1–4) or *Hin*dIII (lanes 5–8) Lanes 1 and 5, 380 B-ALL cell line, lanes 2 and 6, Daudi Burkitt's lymphoma cell line, lanes 3 and 7, P3HR-1 Burkitt's lymphoma cell line, lanes 4 and 8, GM 1056 lymphoblastoid cell line
Methods Genomic DNA (10 μg) was digested with the indicated restriction enzyme, separated on a 0 7% agarose gel, and transferred to a nitrocellulose filter following denaturation and neutralization The probe was ^{32}P-labelled by nick-translation Hybridization was carried out in 4×SSC, 2×Denhardt's solution and 50% formamide at 37 °C for 24 h, and washing was to a final stringency of 2×SSC at 65 °C Blots were exposed for 12 h at −70 °C with an intensifying screen The size of the λ *Hin*dIII digested marker DNA is in kb

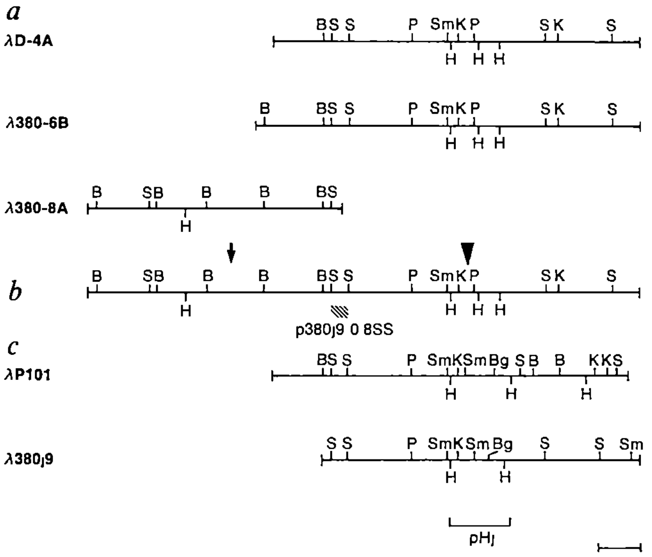

Fig 3 *a*, Restriction maps of the normal chromosome 8 recombinant clones from the Daudi Burkitt's lymphoma (λ D-4A) and the 380 B-ALL (λ 380-6B and 380-8A) cell lines The horizontal lines represent insert DNA from the respective clones *b*, Restriction map of the normal chromosome 8 region deduced from *a* Triangle, P3HR-1 and 380 breakpoints, arrow, putative Daudi breakpoint *c*, Restriction map of the 14q$^+$ breakpoint clone from the P3HR-1 Burkitt's lymphoma (λP101) and 380 (λ380j9) cell lines The point at which the breakpoint clones diverge from the chromosome 8 map is indicated by the triangle in *b* Cleavage sites of the restriction enzymes S, *Sst*I, P, *Pst*I, Sm, *Sma*I, H, *Hin*dIII, K, *Kpn*I and Bg, *Bgl*II Scale bar, 2 kb A representative genomic library was prepared from DNA of P3HR-1 and Daudi cells Cloning procedures in the λ phage EMBL3A (ref 34) were essentially as described[12] Libraries were screened with the p380j9 0 8 SS probe Approximately 350,000 independent recombinant phages in the P3HR-1 library were screened, as well as approximately 800,000 phages in the Daudi library, and 350,000 clones in the previously constructed 380 genomic library[12] The P3HR-1 library was initially screened with the pHj joining segment probe[12] Six recombinant clones were obtained These were secondarily screened with the chromosome 8-specific p380j9 0 8SS DNA probe (Fig 1) Of the six initial positives, one clone, designated λP101, contained homologous sequences

12 and Fig 1) Probe p380j9 0 8SS was used to screen the 380, P3HR-1 and Daudi libraries Two clones were obtained from the 380 library and one each from P3HR-1 and Daudi These clones were subjected to analysis by restriction endonuclease digestion and Southern blotting The resulting physical restriction maps are illustrated in Fig 3 Several features are apparent First, the clones are identical in the region containing the p380j9 0 8SS sequence derived from chromosome 8 Second, the Daudi (λD4) and 380 λ 380-6B and λ380-8A) clones overlap and constitute the normal, uninterrupted chromosome 8 sequence Third, the breakpoints of the 380 (λ380j9) and P3HR-1 (λP101) clones align almost precisely Fourth, although the Daudi breakpoint clone was not obtained, genomic Southern blot data allow us to map the break to the middle of the 3 5 kb *Bam*HI fragment on chromosome 8 (indicated) Finally, comparison of this region with published restriction map[13] of the sequences surrounding c-*myc* on chromosome 8 reveals no similarity ·the breakpoints are situated 5′ to the *Bam*H1 site 15 kb upstream of the first c-*myc* exon

Because the same site on chromosome 8 is involved in the translocation to chromosome 14 in P3HR-1 and 380, we sequenced this region for both the normal and breakpoint clones (Fig 4) The 380 sequence is identical to that of the Daudi normal chromosome 8 allele but diverges six nucleotides 5′ of the *Pst*I site There follows a stretch of 22 nucleotides having homology to neither chromosome 8 nor chromosome 14 sequences The next nucleotide corresponds to the twenty-first nucleotide of the heavy chain joining segment J6 (ref 14), and the remainder of the 380 clone is homologous to this segment, with several single base substitutions The P3HR-1 breakpoint is 63 bp 5′ of the 380 breakpoint on chromosome 8 Upstream of this site, λP101 is homologous to λD4, 3′ it is homologous to a region beginning 90 nucleotides 5′ of J5 This result verifies the somatic cell hybrid data[15] implicating the J_H segments in the P3HR-1 translocation

Fig. 4 Nucleotide sequence of the joining site between chromosome 8 and 14 in P3HR-1 and 380, and the corresponding normal chromosome 8 region Triangles designate points at which the P3HR-1 and 380 sequences diverge from the chromosome 8 sequence, vertical lines indicate identical nucleotides Bold sequences indicate the J5 and J6 heavy chain joining segments[23] The bracketed regions are conserved heptamer-nonamer signal sequences, and a putative N region is underlined at the 380 joining site The underlined region of chromosome 14 comprises 16 codons and a splice signal (see text) DNA sequences were obtained using the Sanger dideoxy chain termination method[33] on M13[34] subclones from the *Kpn*I site (Fig 3) through the chromosome 14 sequences The *Pst*I site on λD-4A, and the *Sma*I site on λ380j9 (Fig 3) are denoted by double underlines

Both these sequences exhibit features suggesting that the recombinase mediating V-D-J joining was involved in these translocations This enzyme is responsible for the rearrangement of the immunoglobin locus during B-cell maturation[9], and is thought to function similarly in T cells[16] The putative enzyme is thought to recognize heptamer-nonamer signal sequences[17] apposed to each recombining segment Recombination only occurs when a signal sequence having a 12 base spacer is paired with one having a 23 base spacer[18] Moreover, V-D-J recombination results in deletions, substitutions[9], or in the addition of extra nucleotides (N regions), presumably by the action of terminal deoxynucleotide transferase[19] The 380 joining site shows several of these points The breakpoint on chromosome 8 occurs at a sequence homologous to the canonical heptamer (bracketed in Fig 4) Although a satisfactory nonamer is lacking, a heptamer may be sufficient for recombinase function[20,21] The alignment of the J6 segment with the 380 sequence clearly demonstrates that the heptamer-nonamer on chromosome 14 are ideally positioned for a recombination event Additionally, the stretch of extra bases corresponds to an N region, and includes a characteristic stretch of GCs[9] At the P3HR-1 breakpoint, a heptamer is again positioned at the joining site on chromosome 8, twelve bases downstream is a nonamer On chromosome 14, an almost perfect heptamer-nonamer is found, with a 23 bp spacer (shown in Fig 4) Thus recombination according to the 12/23 rule could take place Moreover, the 50 nucleotides 3′ of the nonamer comprise 16 codons, including a stop codon, and a GT splice signal (Fig 4) This sequence has the characteristics of a pseudo-joining segment, and could constitute an additional feature recognized by the recombinase Imprecision is also observed at the breakpoint, as exemplified by the two base mismatch six bases 3′ of the break Lastly, both breakpoints exhibit single base changes which may be a consequence of somatic mutation following V-D-J recombination[9] In both these translocations, then, nucleotide sequence analysis of the sites of chromosome-joining strongly suggests that the translocation occurred in a sequence-specific manner through the action of the recombinase

Recombinase action can be related to the cell of origin of these tumours Both originated in a pre-B cell[22] or sIg^+ cell[20,21] capable of further immunoglobulin gene rearrangement Taken together with similar findings in B-CLL[10] and follicular lymphoma[11], these data suggest that tumour polyclonality[23] should be interpreted as continued gene rearrangement following malignant transformation Moreover, in most sporadic Burkitt's lymphoma cases the chromosome breakpoints are to the first exon of c-*myc*[24-29], and involve the μ, γ, or α switch regions[24-29] However, in most African Burkitt's lymphomas, rearrangements of the c-*myc* locus cannot be detected by Southern blot hybridization[4,30], and translocations into the V_H (ref 2) or J_H (ref 15) region have been found We and others have previously shown that B cells from sporadic Burkitt's lymphomas are more differentiated than those from African Burkitt's lymphomas[30-32] Our results support this hypothesis and suggest that in the African Burkitt's lymphoma P3HR-1, and in the 380 B-ALL, the translocation occurred at the pre-B cell stage of differentiation during heavy chain gene rearrangement The recombinase joined two separated segments of DNA on different chromosomes instead of two segments on the same chromosome Thus in the endemic (African) Burkitt's lymphomas the translocations probably result from mistakes in V-D-J joining while in the sporadic cases it is possible that they result from mistakes during heavy chain class switching in more differentiated B cells

Finally, comparison of the region of chromosome 8 involved in the translocations with the region surrounding c-*myc*[13] shows no overlap Calculations from the extent of the c-*myc* restriction map[13], which covers ~20 kb 5′ of the first exon, and the extent of our clones, which cover at least 15 kb away from the chromosome 14 junction, lead us to conclude that c-*myc* is at least 35 kb distant from the breakpoint in these instances The precedent for transcriptional control acting over such distances comes from the IgH enhancer, which has been demonstrated to act over at least 17 5 kb[33] In each of these translocations, c-*myc* is situated 5′ of the enhancer located between J_H and S_μ This would appear to be the logical explanation for the deregulation of c-*myc* secondary to the t(8, 14) chromosome translocation

We thank Dr Kay Huebner for supplying the somatic cell hybrid DNAs, Dr Masaharu Isobe for many useful comments, Ms Debbie Jiampetti for technical assistance and Mrs K Reinersmann for preparation of this manuscript F G H is a trainee of the Medical Scientist Training Program, NIH 5 T32 GM 07170 Supported by The Outstanding Investigator Award from the National Cancer Institute (C M C)

Implications of fragile X expression in normal males for the nature of the mutation

David H. Ledbetter*, Susan A. Ledbetter* & Robert L. Nussbaum†

The fragile site at Xq27, associated with a common form of X-linked mental retardation (XLMR)[1], is expressed in a variable proportion of the peripheral lymphocytes of affected males when the cells are cultured under thymidylate stress (Td stress) produced by folate or thymidylate deprivation. Some clinically normal males—transmitting males—are known to carry and transmit the fragile X mutation and yet show no cytogenetic expression in lymphocytes[2,3]. Normal males with no family history of X-linked mental retardation express the site only rarely. When the fragile X chromosome from affected males is isolated in a rodent genetic background by somatic cell hybridization, the level of expression is similar to that seen in lymphocytes under Td stress[4–6]. Here we show that X chromosomes from two transmitting males and two normal control males, all of which were fragile X negative in lymphocytes or lymphoblasts, could be made to express the fragile site in hybrids, although at levels that were below those seen in hybrids from affected males. Furthermore, transmitting males could be differentiated from normal males by their significantly higher expression rates when hybrids were exposed to caffeine[7] before cytogenetic harvest. One male chimpanzee also showed low level expression in hybrid cells. These data suggest that (1) the hybrid system lowers the threshold for fragile X expression, (2) a fragile site at Xq27 may be present on all human and chimpanzee X chromosomes and constitutes a previously unrecognized common fragile site and (3) the hybrid system with caffeine post-treatment can distinguish between the common Xq27 fragile site of control males, the occult mutant fragile site of a transmitting male, and the fully expressed fragile site of an affected male with XLMR. Thus the mutation producing XLMR may represent a multi-step alteration of a naturally occurring DNA sequence producing a continuum of cytogenetic expression and a threshold for clinical manifestation.

We and others have demonstrated that rodent cells (hamster or mouse) are permissive for fragile X expression when somatic cell hybrids are created containing the X chromosome of affected males[4–6,8] This approach allows the isolation of different fragile X mutations on a homogeneous, xenogeneic background Hybrid expression levels are similar to those observed in the human parental cells, suggesting that expression is an intrinsic property of the site and is not influenced by the presence or absence of human autosomal loci[4,6] We have reported preliminary hybrid studies of a clinically normal, transmitting male who showed no expression in lymphocytes or lymphoblasts in multiple laboratories[6,7] Low frequency expression (2%) was observed in hybrids and was enhanced to 12% by caffeine This preliminary observation suggested that the hybrid system lowers the threshold for induction or detection of cytogenetic expression in individuals who carry the mutation but show no cytogenetic expression in routine lymphocyte studies We have analysed additional hybrid clones from this transmitting male and have extended our studies to include a second unrelated transmitting male, two normal control males with no family history of X-linked mental retardation, and one male chimpanzee

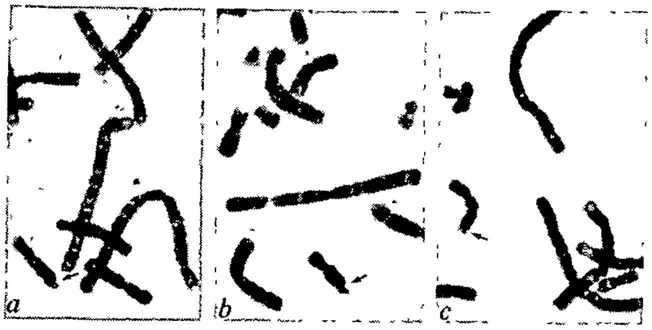

Fig. 1 Partial G-banded metaphases showing fragile X expression in hybrid cells from normal control males N1 (*a*), N2 (*b*), and a chimpanzee (*c*)

One to five hybrid clones from each individual were isolated, characterized, and used for fragile site induction studies The clones studied, parental cell types and their chromosome constitution are shown in Table 1 The number of human chromosomes present varied from 1 (the X only) to 15, with an average of six

Fragile X expression frequencies in parental cells and hybrid cells are shown in Table 2 The two affected males showed lymphoblast expression frequencies of 29% (GM4025) and 40% (DT) over several experiments Under conditions of Td stress alone, hybrid expression was 27% and 23%, respectively These levels were increased to 43% and 30% by caffeine post-treatment Overall the hybrid expression rates were similar to those found in the parental cells

In the two transmitting males, no expression was observed in 200 (MGL66) or 100 (LC) lymphoblast mitoses This is consistent with previous studies, in which lymphocytes and lymphoblasts have been repeatedly negative (refs 9, 10, P A Jacobs, unpublished, W T Brown, unpublished) Under Td stress alone, hybrid cells from each transmitting male showed 2% expression (22/900 and 9/400) over multiple experiments With caffeine, expression increased in the hybrids from both transmitting males to 12% (62/500 and 12/100) This significant enhancement by caffeine is similar to that previously observed in a low-expressing carrier female[6,7]

Several investigators have proposed that the occurrence of clinically normal, transmitting males may be due to the presence of one or more autosomal modifying loci which suppress the major gene on the X chromosome[2,11] Segregation data argue against this hypothesis[12], but no previous experiments have addressed the issue Segregation of the proposed autosomal suppressor by somatic cell hybridization might be expected to produce expression levels equivalent to those of affected males The significantly lower expression rates observed in six independent clones from two unrelated transmitting males suggest an alternative explanation, that the hybrid system lowers the threshold for detection of low level fragile site expression in transmitting males with an occult or incomplete mutation

A total of 100 mitoses from peripheral lymphocytes were scored from each of two normal control males with no family

Parental cell types used for fragile X expression and somatic cell fusion were either lymphoblasts, lymphocytes or fibroblasts GM4025 is a lymphoblast line from an affected fragile X male obtained from the Human Genetic Mutant Cell Repository DT is a lymphoblast line produced by Epstein–Barr-virus transformation of an unrelated affected male with a 40% lymphocyte expression rate[1] MGL66 is a lymphoblast line provided by Dr P A Jacobs from a transmitting male who showed no expression in lymphocytes[9] LC is a lymphoblast line provided by Dr W T Brown from a transmitting male with no expression in lymphocytes[10] Peripheral blood was obtained from two clinically normal control males (N1, N2) with no family history of mental retardation for fragile X expression and for fusion A fibroblast cell line on a male chimpanzee (*Pan troglodytes*) was obtained from the Human Genetic Mutant Cell Repository (AG6939A) Hybrids were constructed as previously described[4] from parental cells and RJK88, an HPRT$^-$ Chinese hamster V79 derivative or 88 13, a thymidylate synthase deficient (TS$^-$) mutant of RJK88[5] Hybrids were maintained in Dulbecco's modified Eagle's medium+10% FCS with hypoxanthine (10^{-4} M) and azaserine (5×10^{-4} M) The chromosome composition of each hybrid was determined by trypsin G-banding analysis

* Data are from this work except where stated

The number of fragile X positive cells observed over mitoses scored is given in parentheses Each condition represents at least two experiments For fragile X induction, lymphoblasts and lymphocytes were cultured in medium RPMI 1640+10% FCS and treated with FUdR (5×10^{-8} M and 1×10^{-7} M) or excess thymidine (1-2 mM) for the last 24 hours before standard cytogenetic harvest For hybrids, induction by thymidylate (Td) stress alone was by treatment with FUdR (10^{-9} M-10^{-7} M) or excess thymidine (1-2 mM) in most hybrids, and by thymidine deprivation in the TS$^-$ hybrids[5] for 12-16 hours Caffeine post-treatment was used to enhance expression by addition of 2 mM caffeine for the last 1-2 hours before harvest[7] All slides were trypsin G-banded and at least 50 cells per condition scored for fragile X expression whenever possible Scoring of the lymphocytes and hybrids from the two normal control males was done blindly in the sense that the technicians doing the analysis were unaware of the nature of the experiment and the clinical status of the individuals whose cells they were scoring

history of X-linked mental retardation No fragile X chromosomes were observed However, in blind experiments, 2% expression (5/250 and 3/200) was consistently observed in hybrid cells under Td stress alone This level is identical to that observed in the clinically normal transmitting males Caffeine post-treatment increased expression to 4% (8/200) and 5% (9/187), significantly less than the 12% level of transmitting males ($\chi^2=16\ 8$, $P<0\ 01$) The total of 25 fragile X positive cells observed in the two normal individuals (examples in Fig 1) is much higher than expected by random chromosome breakage Our findings suggest that previous reports of single cell occurrences of fragile X cells in normal controls (reviewed in ref 13) are not artefacts, but represent low level expression of a common fragile site at Xq27 in normal individuals

Common fragile sites are present in both homologues of a chromosome in most or all individuals, whereas rare fragile sites are usually found in just one homologue and occur in less than 1% of the population[14] The relationship between rare and common fragile sites is unclear Their mechanism of induction is similar, though not identical[15] Interestingly, 6 of 18 rare fragile sites occur in chromosome bands which also contain a common fragile site[14] This has led to speculation that a rare fragile site may represent an alteration (mutation) in a pre-existing common fragile site[16,17] Yunis and Soreng[16] demonstrated the presence of common fragile sites in chimpanzee and gorilla in sites homologous to those of man If Xq27 is a common fragile site in humans, it should also be present in these species We therefore extended our hybrid studies to a male chimpanzee No fragile X induction studies were attempted on the parental fibroblast cells, as fragile X expression is generally poor in fibroblasts compared to lymphocytes or lymphoblasts even in affected fragile X males In hybrid cells under Td stress alone, one fragile X cell was observed out of 400 mitoses scored With caffeine post-treatment, 4 positive cells out of 250 were seen (Fig 1*c*) Although this frequency of expression is lower than that seen in normal human males ($\chi^2=4\ 98$, $P<0\ 05$), our impression is that this may be due to the relatively poor growth of this hybrid clone Despite the lower frequency, the presence of a fragile site at Xq27 in a chimpanzee is consistent with the existence of a common fragile site whose origin is ancestral to the human-chimpanzee divergence

Use of caffeine to enhance fragile X expression in hybrid cells was crucial to the discrimination between transmitting and normal males Yunis and Soreng[16] first showed that caffeine, which has synergistic effects with a variety of DNA damaging agents, enhances expression of common fragile sites and fragile X when used in conjunction with fluorodeoxyuridine (FUdR) Although we[7] and others[18-19] have failed to replicate caffeine's enhancing effect on fragile X expression in lymphocytes or lymphoblasts, it has consistently increased expression in hybrid cells[6,7] This difference may be due to the fact that caffeine's effect on fragile X expression appears to be indirect it inhibits the mitotic delay usually associated with DNA damage, thereby reducing the time available for DNA replication, repair and chromosome condensation[7] The effect may vary among cell types with different cell cycle characteristics, particularly different lengths of G_2

The high prevalence and unusual segregation patterns observed in fragile X syndrome suggest that it is not a classical X-linked mutation[3,12,20] The single most unusual characteristic of its inheritance is its variable penetrance within pedigrees For example, the penetrance of mental retardation is significantly lower in offspring of mothers of transmitting males than in offspring of daughters of transmitting males[12] This observation has been referred to as the 'Sherman paradox'[21] and must be explained by any model addressing inheritance of fragile X The unique ability of the hybrid system to induce fragile X expression in transmitting and normal males and to demonstrate a continuum of cytogenetic expression (low in normal males, higher in transmitting males, highest in affected males) argues strongly against the involvement of autosomal modifying loci in this disorder Instead, the presence of a common fragile site at Xq27 is consistent with the multi-step mutation models of Pembrey *et al*[20] and Nussbaum *et al*[22]

We speculate that recombination between two normal X chromosomes at the Xq27 common fragile site region may be the mechanism for an initiation event, producing a clinically normal transmitting male or carrier female Segregation data demonstrates that progression to the full XLMR mutation occurs only in females[20] (who have two X chromosomes), also suggesting that meiotic recombination is involved These recombination events may produce variation in the length or copy number of a DNA sequence at Xq27, which at some threshold level disrupts the function of a neighbouring gene and produces XLMR Quantitative variation in the size of the fragile site DNA region may also explain the variable recombination distances between polymorphic DNA markers observed among fragile X families[23] Thus, our data suggest that a normal DNA sequence at Xq27 may be altered to produce a continuous quantitative variation in fragile site DNA resulting in varying degrees of cytogenetic expression and a threshold for clinical manifestation of the mutation

We thank Drs P A Jacobs and W T Brown for providing lymphoblastoid cell lines on transmitting males This work was supported by NIH RO1 HD20227, the Robert J Kleberg, Jr Center for Human Genetics, and the Howard Hughes Medical Institute R L N is an Associate Investigator in the Howard Hughes Medical Institute

Analysis of enzymatically amplified β-globin and HLA-DQα DNA with allele-specific oligonucleotide probes

Randall K. Saiki, Teodorica L. Bugawan,

Allelic sequence variation has been analysed by synthetic oligonucleotide hybridization probes which can detect single base substitutions in human genomic DNA[1–3]. An allele-specific oligonucleotide (ASO) will only anneal to sequences that match it perfectly, a single mismatch being sufficient to prevent hybridization under appropriate conditions[4]. To improve the sensitivity, specificity and simplicity of this approach, we used the polymerase chain reaction (PCR) procedure[5] to enzymatically amplify a specific segment of the β-globin or HLA-DQα gene in human genomic DNA before hybridization with ASOs This *in vitro* amplification method, which produces a $>10^5$-fold increase in the amount of target sequence, permits the analysis of allelic variation with as little as 1 ng of genomic DNA and the use of a simple 'dot blot' for probe hybridization. As a further simplification, PCR amplification has been performed directly on crude cell lysates, eliminating the need for DNA purification.

^{32}P-labelled ASO probes have been used in the analysis of a number of genetic diseases caused by single base mutations, including sickle cell anaemia[1], α-1 anti-trypsin deficiency[2] and β-thalassemia[3] Although the ASO method is a powerful diagnostic tool, it requires 5 to 10 μg of genomic DNA, gel-purified high specific activity probes and several days of autoradiographic exposure The short oligomer probes (usually 19 bases long) also hybridize to other genomic sequences so that restriction endonuclease digestion and gel electrophoresis are required to separate the target sequence from the bulk of the genomic DNA In order to develop a simple, sensitive method, we chose the sickle cell anaemia and haemoglobin C mutations in the sixth codon of the β-globin gene[6] as a model system for genetic diagnosis We used ASOs specific for the normal (β^A), sickle cell (β^S), and haemoglobin C (β^C) sequences as probes to detect these alleles in PCR-amplified genomic samples Figure 1 shows the sequence of the PCR primers (PC03 and PC04), the ASO probes (19A, 19S and 19C), and their relationship to the β-globin gene The PCR primers, both 20 bases in length, anneal to opposite strands of the genomic DNA flanking the target sequence[7] These primers are positioned so that the polymerase-catalysed, template-directed extension product of one primer can serve as a template strand for the other In this configuration, repeated cycles of denaturation, primer annealing, and primer extension, result in the exponential accumulation of a 110-base pair (bp) β-globin fragment, with a length defined by the distance between the 5′ ends of the PCR primers For example, 20 cycles of PCR amplification with PC03 and PC04 as primers produce a 220,000-fold increase in the amount of β-globin target

Fig 1 Sequence of the PCR primers and ASO probes and their relationship to the β-globin gene. The two PCR primers, PC03 and PC04, are 20 bases long and are complementary to the (−) and (+) strands, respectively. The three ASO probes, 19A, 19S, and 19C, are 19 bases long and span codons 4–17 of the gene[8]. 19A is complementary to the normal β-globin allele (β^A), 19S to the sickle cell allele (β^S), and 19C to the haemoglobin C allele (β^C). Boxes, single base mutations of β^S and β^C.

sequence[7]. The sequences of the 19-base ASO probes used here are identical to those described previously by Studencki *et al*[8].

DNA was extracted from six blood samples from individuals with every possible diploid combination of the β^A, β^S, and β^C alleles and from the cell line GMZ 2064, which has a homozygous deletion of the β-globin gene[9]. The DNA (1 μg from each sample) was subjected to 25 cycles of PCR amplification and 1/30th of the reaction product (33 ng) applied to a nylon filter as a 'dot blot'. Three replicate filters were prepared and each was hybridized with one of the three ^{32}P-labelled ASOs under stringent conditions. The autoradiogram (Fig 2) clearly indicates that each ASO annealed only to those DNA samples which contained at least one copy of the β-globin allele to which the probe was perfectly matched. For example, the β^A-specific probe, 19A, hybridized only to samples AA ($\beta^A\beta^A$), AS ($\beta^A\beta^S$), and AC ($\beta^A\beta^C$). The high degree of specificity contributed by PCR amplification is further emphasized by the lack of any detectable hybridization of the ASO probes to the GM2064 deletion mutant. The frequency of the specific β-globin target in PCR amplified DNA has been estimated by the analysis of cloned amplification products to be approximately 1%, an enrichment of $>10^5$ over unamplified genomic DNA[10]. It is this substantial reduction of complexity that allows the application of 19-base probes in a dot blot format and also makes possible the use of even shorter ASO probes capable of allelic discrimination under less stringent conditions (data not shown).

To estimate the minimum amount of DNA detectable, eight serial dilutions containing 1 to 128 ng of genomic AA DNA were amplified by 25 cycles and half of each sample was applied to a dot blot, then hybridized with the 19A probe. Equivalent dilutions of the 25-cycle amplifications of AA and SS DNA prepared in the previous experiment were included as controls. The autoradiogram (Fig 3) reveals signals in all AA samples, the overall efficiency of amplification with nanogram quantities of template DNA is comparable to that obtained with 1 μg. Moreover, the subnanogram detection limit obtained with ^{32}P-labelled oligonucleotide probes suggests that the analysis of nanogram quantities of genomic DNA with nonradioactive ASO probes (for example, biotin-labelled) should be feasible. Since one nanogram is the amount of genomic DNA present in only 150 diploid cells (assuming a haploid genome size of 3×10^9 bp)

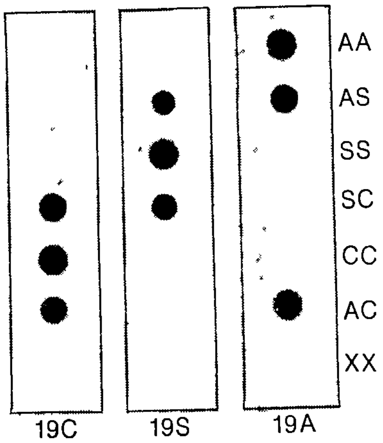

Fig 2 Genotype analysis of PCR-amplified genomic DNA using ASO probes. DNA was extracted from the buffy coat fractions of clinical blood samples of known β-globin genotype[11] and 1 μg portions of AA ($\beta^A\beta^A$), AS($\beta^A\beta^S$), SS ($\beta^S\beta^S$), SC ($\beta^S\beta^S$), CC ($\beta^C\beta^C$), AC ($\beta^A\beta^C$), and GM2064 (deletion mutant, see text) DNA were subjected to 25 cycles of PCR amplification as described previously[7]. Briefly, the samples were dispensed in 100 μl PCR reaction buffer (50 mM NaCl, 10 nM Tris, *p*H 7.6, 10 mM $MgCl_2$, 1 μM PC03, 1 μM PC04, 1.5 mM dATP, 1.5 mM dCTP, 1.5 mM dTTP, and 1.5 mM dGTP). After heating (10 min at 95 °C) to denature the DNA, the samples were transferred to a 30 °C heat block for 2 min to allow the primers to anneal to their target sequences. Primer extension was initiated by addition of one unit of Klenow fragment of *Escherichia coli* polymerase I (New England Biolabs) and incubated for 2 min at 30 °C. This cycle of heating, annealing, and extension was repeated 24 times, subsequent denaturations were by heating for 2 min. The final volume after 25 cycles was 150 μl. One-thirtieth of each reaction, (5 μl, containing 33 ng of the original genomic DNA), was adjusted to 0.4 N NaOH, 25 mM EDTA[17] in a 200 μl volume and applied to a Genatran-45 nylon filter (Plasco) with a Bio-Dot spotting apparatus (Bio-Rad). Three replicate filters were prepared. The ASO probes were phosphorylated at their 5′-termini with [γ-^{32}P]ATP and polynucleotide kinase and purified by spin dialysis[11]. The specific activities of the probes were between 3.5 and 4.5 μCi pmol^{-1}. Each filter was prehybridized individually in 8 ml 5×SSPE, 5× Denhardt, 0.5% SDS for 30 min at 55 °C. Probe (1 pmol) was then added and hybridized at 55 °C for 1 h. Filters rinsed twice in 2× SSPE, 0.1% SDS at room temperature, followed by a high stringency wash in 5×SSPE, 0.1% SDS for 10 min at 55 °C (for 19C) or 60 °C (for 19A and 19S) and autoradiographed for 2.5 h at −80 °C with a single intensification screen (Dupont Lightning Plus).

we considered the possibility that a crude lysate from a small number of cells would contain sufficiently little cellular debris to allow the DNA to serve as template for the PCR amplification procedure. Eight dilutions containing 75 to 9,600 cells from each of the cell lines MOLT-4 ($\beta^A\beta^A$)[11], SC-1 ($\beta^S\beta^S$)[11], and GM2064 were heated at 95 °C to lyse the cells and subjected to 25 cycles of amplification without purification. Equivalent amounts of purified MOLT-4 DNA were included as controls. The amplified samples were divided onto two dot blots and hybridized with the 19A and 19S probes. The autoradiogram (Fig 4) shows a positive signal in an unfractionated cell lysate of only 75 cells. The efficiency of amplification appears to be only two- to three-fold less than with equivalent amounts of purified DNA (MOLT-4 is reported to be 90% tetraploid (A. Green, personal communication) so that 150 cells would be expected to contain 2 ng of genomic DNA). Both ASO probes retain allele specificity. 19A anneals only to MOLT-4 DNA and 19S only to SC-1 DNA. The variation from the expected two-fold reduction of signal intensities may reflect dilution artefacts associated with manipulating such small numbers of cells, and the significant reduction in signal intensity seen in both 9,600-cell samples may be due to inhibition of the amplification process by cellular

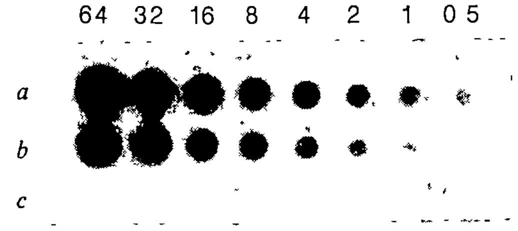

Fig 3 PCR amplification of sub-microgram amounts of genomic DNA *a*, Eight serial dilutions containing 128, 64, 32, 16, 8, 4, 2, and 1 ng of sample AA DNA were amplified by 25 cycles One half of the amplification product (64 to 0 5 ng) was applied to a filter (row A) Controls consisted of equivalent dilutions of *b*, previously amplified AA and *c*, previously amplified SS DNA (Fig 2) The filter was hybridized with the 19A probe and exposed for 6 h See Fig 2 (legend) for methods

debris Use of unfractionated lysate reduces the time required for analysis to <8 hours

PCR amplification and ASO hybridization have also been used to analyse genetic polymorphism at the HLA-DQα locus, which has localized allelic variability in the second exon (Fig 5*a*) Using PCR primers complementary to conserved regions of this exon, a 242-bp fragment of DQα was amplified from DNA samples isolated from nine homozygous typing cell lines (HTC) and from two heterozygous cell lines, then hybridized with four different ASO probes (Figure 5*b*) The sequence of these probes was based on published data[12-15] as well as on our determinations of the sequences of complementary DNA, genomic and PCR-amplified clones (ref 12 and Fig 5, legend) Polymorphism in the HLA-DQ region, which consists of one α and one β chain locus, is detected serologically as the DQw1, DQw2, and DQw3 antigen series[16] The DQA1 probe hybridizes selectively to amplified DNA from all cells typed as DQw1, which is associated with the DR1, DR2, and DRw6 serological types, As expected from the gene sequence, this probe also hybridizes to the DNA from the DR8 homozygous cell line TAB which is also DQw1 The DQA3 probe hybridizes to DNA from the DR3, DQw2 line AVL as well as to the unknown sequence in the DR5, DQw3 line JGL suggesting that these DQα alleles are homologous Since DQA3 did not hybridize to the DNA from the other DQw3 lines (DKB and KOZ), there must be DQα sequence heterogeneity within this specificity Thus the allelic variation in the HLA-DQα locus detected by this method appears to be greater than the polymorphic series defined by serological typing, and can also be more precisely localized This approach is at present being applied to the analysis of polymorphism in the HLA-DQβ and DRβ loci

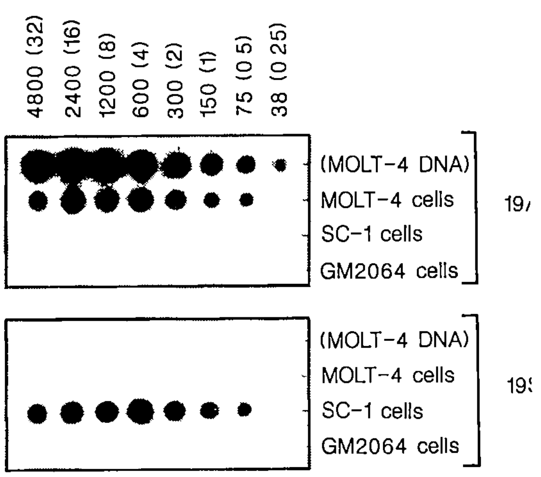

Fig 4 Genotype analysis of PCR-amplified crude cell lysates using ASO probes Cell concentrations of the cell lines MOLT-4 ($\beta^A\beta^A$), SC-1 ($\beta^S\beta^S$), and GM2064 (see text) were determined with a haemocytometer Eight serial dilutions in PBS were prepared at 9 6 × 10^5, 4 8 × 10^5, 2 4 × 10^5, 1 2 × 10^5, 6 0 × 10^4, 3 0 × 10^4, 1 5 × 10^4, and 7 5 × 10^3 cells per ml Ten µl of each dilution (containing 9,600, 4,800, 2,400, 1,200, 600, 300, 150 and 75 cells), were mixed with 35 µl H_2O and heated for 10 min at 95 °C to lyse the cells The lysates were added to 55 µl, 1 8 × PCR buffer (containing salts, primers, and dNTPs) and immediately subjected to 25 cycles of amplification Equivalent amounts (64 to 0 5 ng) of purified MOLT-4 genomic DNA were also amplified The PCR reaction products were divided onto two filters, probed with 19A and 19S and exposed for 6 h Methods are as for Fig 2 except that the amplification buffer included 10% DMSO (v/v), the annealing and extension reactions were performed at 37 °C instead of 30 °C[10] and the PCR amplification procedure was carried out in an automated device designed by the Cetus Instrumentation group

With the use of nonisotopic probes and PCR automation (see Figs 4 and 5), this procedure, combining *in vitro* target

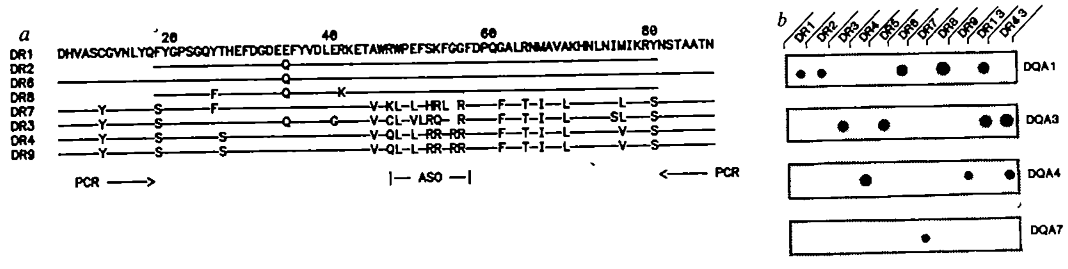

Fig. 5 Detection of allelic variation in HLA-DQα sequences. *a*, Allelic variation in the HLA-DQα gene, *b*, detection of HLA-DQα alleles Protein sequences of the variable outer domain of the HLA-DQα chain, derived from cloned cDNA and PCR-amplified[10] sequences, are shown as differences from the sequence found in the DR1 (ref 13) haplotype (upper line), and grouped to emphasize their similarities The sequences from the DR1, DR2 (ref 13) and DR6 (ref 14) haplotypes (DQw1) are closely related, and those from the DR4 (ref 14) and DR9 (ref 16) haplotypes (DQw3) are identical The region between positions 47 and 56 shows the greatest variation, and was therefore chosen as a target for four different ASO probes In this segment, the DQα sequences from the DR1, 2, 6, and 8 (ref 13) haplotypes are identical and homologous to the DQA1 ASO(5'-AACCTCCAAATTTGCTGAACTCAGGCCACCG-3') The sequence from the DR7 (ref 15) haplotype is homologous to the DQA7 ASO (TTCCACAGACTTAGATTTG) and the DR3 sequence (ref 14) to the DQA3 probe (TGTTTGCCTGTTCTCAGAC) The sequences from the DR4 and DR9 haplotypes are identical and homogous to the DQA4 probe (TTCCGCAGATTTAGAAGAT) *b*, DNA was isolated[11] from nine homozygous typing cell lines and two heterozygous cell lines with HLA-DQα types DR1 (LG2), DR2 (PGF), DR3 (AVL), DR4 (DKB), DR5 (JGL), DR6 (APD), DR7 (LBF), DR8 (TAB), DR9 (KOZ), DR1,3 (B302), DR3,4 (B303) Each DNA sample (1 µg) was PCR-amplified for 28 cycles with the DQα primers as described (Fig 4) The degree of amplification was determined by hybridization to a DQα cDNA probe labelled with ^{32}P by nick-translation, and equal amounts of product (2–10% of the final reaction volume) was denatured with two volumes of 0 5 M NaOH, 1 5 M NaCl After neutralization with 0 5 M Tris, *p*H 7, 1 5 M NaCl to a final volume of 200 µl, the DNA was spotted in four replicates on MSI Nylon 66 (Fischer Scientific) and fixed to the filters by UV irradiation for 4 min The filters were prehybridized for 1 h at 50° in 6 × SSPE, 10 × Denhardt, 0 5% SDS, and hybridized overnight with the ASO probes (at 2 × 10^5 cpm ml^{-1}) labelled with ^{32}P as described (Fig 2), washed for 10 min at 37° in 0 1 × SSPE, 0 1% SDS, and autoradiographed for 90 min with an intensification screen

amplification and ASO probes in a dot-blot format, promises to be a general and simple method for the detection of allelic variation In addition, the ability to analyse genetic variation rapidly in minute amounts of purified DNA or cell lysates has important implications for a wide variety of genetic analyses

We thank Corey Levenson, Lauri Goda and Dragan Spasic for the synthesis of oligonucleotides, Norm Arnheim for discussions, and Larry Johnson and Richard Leath for instrument and engineering support We also thank John Sninsky for critical review, and Kathy Levenson, Eric Ladner, Tim Culp and Sharon Nilson for preparation of this manuscript

Note added in proof Recently, 50 ng samples of PCR-amplified genomic DNA have been analysed using a biotin-labelled ASO probe

The detection of haemoglobins in distantly-related non-legume plant families[1,2] as well as in the legume families raises the question of whether the origin of the plant haemoglobins was single or multiple. We have isolated a haemoglobin gene from *Parasponia andersonii* (Ulmaceae) which shows more than 50% nucleotide sequence homology with the haemoglobin genes of legume plants and has three introns at identical positions to the leghaemoglobin introns[3-5]. The *Parasponia* gene has homology to haemoglobin genes in another distantly-related nodulating plant, *Casuarina*. It also hybridizes at high stringency to sequences in a related, but non-nodulating genus, *Trema*. We conclude that the globin gene family may be widespread in modern plants, that plant haemoglobins may have a cryptic function in non-symbiotic tissue and that plant haemoglobins have evolved by vertical descent, probably from an ancestor common to modern plants and animals.

A number of plants outside the legume families are known to form nitrogen-fixing root nodules in symbiotic association with *Rhizobium*[6] or actinomycetes[7] Haemoglobin has been detected in nodules of several non-legume plants[1,2] and characterized from *Parasponia* (Ulmaceae)[8,9] and *Casuarina* (Casuarinaceae)[10] Modern systems of plant classification show the known nodulating, haemoglobin-containing species to be widely distributed over several superorders of dicotyledons[7,11,12] (Fig 1) No continuous evolutionary pattern is evident

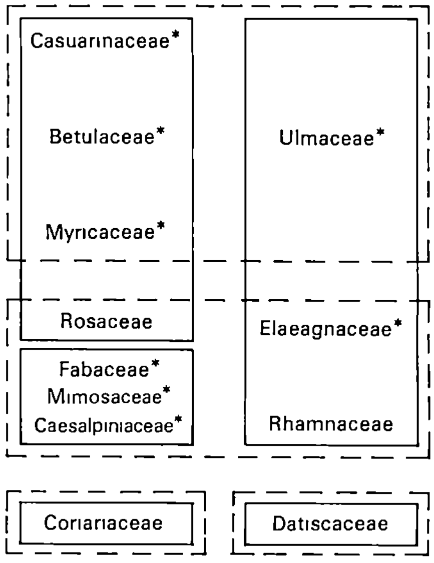

Fig 1 Phylogenetic relationship of dicotyledonous plant families in which some species have been shown to form nitrogen-fixing nodules[7] *Parasponia* is the only genus of the Ulmaceae which has been shown to nodulate, whereas in the legume families nearly all genera of the Fabaceae and Mimosaceae nodulate, the Caesalpiniaceae are mostly non-nodulating Families in which at least one species has been shown to contain nodule haemoglobin[1,2] are marked with an asterisk Solid line, superorders according to Dahlgren[12], dotted line, according to Cronquist[11] Note that these superorders also contain ~150-250 (depending on the classification system) non-nodulating families not listed here The N_2-fixing symbiosis in legumes is always with *Rhizobium* bacteria, *Parasponia* is the only known non-legume genus to be nodulated by *Rhizobium* strains, some of which also infect legumes[6] Other non-legumes undergo symbiosis with *Frankia*, an actinomycete[7]

Although there is 40% protein homology between soybean and *Parasponia* haemoglobin[9], a soybean leghaemoglobin complementary DNA (cDNA) clone did not hybridize to *Parasponia* DNA or nodule RNA, even at reduced stringency A 17mer and a 14mer oligonucleotide sequence deduced from the *P andersonii* haemoglobin I protein sequence[9] were made (see Fig 4) Both oligonucleotides hybridized to an RNA 750 bases long in Northern blots of *Parasponia* nodules (Fig 2*a*) The 17mer was used as primer for synthesis of radioactive cDNA, which was used as a probe, it also hybridized to a 750-base RNA in Northern blots (Fig 2*b*) and identified haemoglobin-specific clones in a nodule cDNA library Two positive clones were analysed, pL209 contained the entire coding region for *Parasponia* haemoglobin I whereas pL201 lacked the first 16 codons Using pL209 as a probe, three independent genomic clones were isolated from a *Bam*HI-EMBL4 genomic library All three clones contained one complete *Parasponia* haemoglobin gene on a 4 8 kilobase (kb) *Eco*RI end fragment within a 13-kb *Bam*HI fragment The sequences of the genomic clones, pL305 and pL401, correspond to the cDNA clones pL209 and pL201 respectively (Fig 3)

The coding region of the *Parasponia* haemoglobin gene spans 486 nucleotides which translate into 161 amino acids excluding the N-terminal Met (Fig 4) Predictions from the DNA sequence showed discrepancies with the published protein sequence[9] Resequencing of the relevant peptides confirmed an additional Phe at position 36, an additional Val at position 73 and a Cys at position 78 instead of the previously reported Thr Four additional amino acids (Ser-Ser-Ser-Glu) were found at the N-terminus (Fig 4) *Parasponia* haemoglobin has the widely conserved globin residues C2-Pro, CD1-Phe, proximal His (E7) and distal His (F8) and, as in other plant haemoglobins, an extended EF-region[13] The protein coding DNA region of the *Parasponia* haemoglobin gene shows more than 50% homology

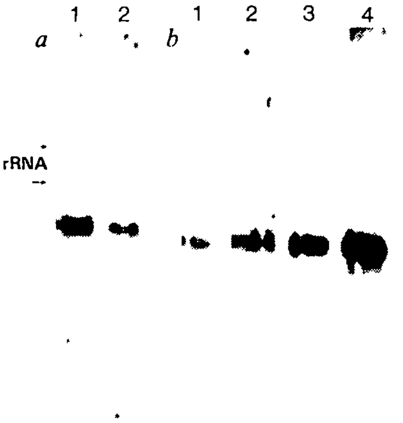

Fig 2 Northern hybridization of *P andersonii* nodule poly(A)$^+$ RNA *a*, Probed with lane 1, the 17mer oligonucleotide, lane 2, the 14mer oligonucleotide *b*, Probed with lane 1, a mixture of 14mer and 17mer, lane 2, 17mer primed cDNA, lane 3, pL201, lane 4, pL209 (see Fig 4 for sequences of the oligonucleotides)
Methods Aseptically-germinated seeds of *P andersonii*, inoculated and nodulated with *Rhizobium* CP283, were transplanted and grown in a sand/vermiculite mixture and cultured using a nitrogen-deficient nutrient medium[6] Root nodules were harvested from a number of plants and RNA was prepared from these according to standard procedures[22] In Northern hybridizations 10 μg of poly(A)$^+$ RNA was run on a formaldehyde agarose gel and hybridized in 50% formamide, 3 5×SSC, 0 75×Denhardt's, 15 mM NaPO$_4$ buffer *p*H 6 5 according to standard procedures[22] Hybridizations with cDNA clones and 17mer-primed cDNA as probes were at 42 °C, but at 32 °C when oligonucleotides were used as probes In oligonucleotide-primed cDNA synthesis, equimolar amounts of poly(A)$^+$ RNA and 17mer were annealed for 30 min at 49 °C in 50 mM Tris/HCl *p*H 8 3, 50 mM KCl, 8 mM MgCl$_2$ The first strand of the cDNA was labelled with [α-^{32}P]dCTP using AMV-reverse transcriptase Oligonucleotides were end labelled with [γ-^{32}P]ATP and T4 polynucleotide kinase

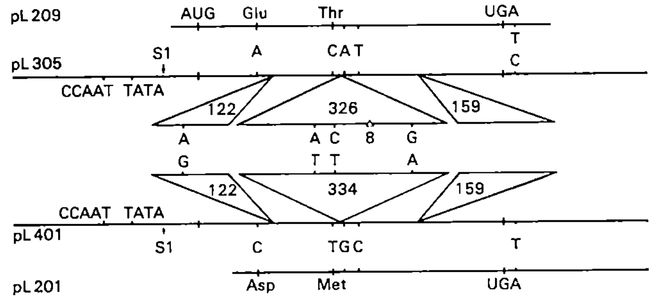

Fig 3 Structure of cDNA clones pL209 and pL201 and genomic clones pL305 and pL401 The cDNA clones contain *Pst*I-*Pst*I inserts of 664 bp (pL201) and 613 bp (pL209) The genomic clones contain a 4 8-kb *Eco*RI fragment each The DNA sequence of pL209 corresponds to pL305, the sequence of pL201 to pL401 Differing nucleotide positions and deduced amino-acid residues are indicated (see also Fig 4) Translational start (ATG) and stop (TGA) codons and presumptive promoter signals for transcription (CCAAT and TATA) and S$_1$-mapped start of transcription are indicated Intron 1 differs by 1 bp between the two genomic clones and intron 2 by 3 bp and an 8-bp deletion/insertion
Methods For cDNA cloning we followed the method of Gubler and Hoffman[23], using oligo(dT) as primer After the final ethanol precipitation in 2 M NH$_4$-acetate the unfractionated double-stranded cDNA population was C-tailed with ^{3}H-dCTP and terminal deoxynucleotidyl transferase, heated for 5 min at 65 °C and annealed for 4 h at 42° to G-tailed pUC8 containing about 12 G residues at *Pst*I ends (gift of W Gerlach) according to standard procedures[22] Transformation of *Escherichia coli* JM83[24] was according to Hanahan[25] Approximately 10^4 white colonies per μg of input *Parasponia* poly(A)$^+$ RNA were isolated on X-gal plates containing 100 μg ml^{-1} ampicillin Colonies were hybridized as described in Fig 3 but with 5×SSC at 42°C with 17mer-primed cDNA as probe Two positively hybridizing clones, pL201 and pL209, were analysed The clones do not contain a poly(A) tail, probably due to the use of RNase H in cDNA cloning A genomic library in λ EMBL4 was made from a 10-15-kb *Bam*HI-fraction of *P andersonii* total DNA This DNA was made from very young leaves taken from a number of plants Plaques were hybridized with pL209 as probe Three independent positive clones (out of 120,000) were identified All contained a 13-kb *Bam*HI fragment containing a 4 8-kb haemoglobin-specific *Eco*RI-fragment These fragments were subcloned into pUC19 from two of the genomic clones giving rise to pL305 and pL401

with leghaemoglobin genes from soybean and kidney bean (Fig 4) DNA homology is higher than the protein homology because amino-acid substitutions in various parts of the haemoglobin protein (for example, positions 18-34, 53-62, 71-78 and 91-100) have, in these regions, allowed mutations in the first codon positions to occur as frequently as in the second and third positions, thus altering the protein faster than its encoding DNA However, the non-coding regions of the *Parasponia* haemoglobin gene have diverged from those of the leghaemoglobin genes Only short sequences, which may be involved in regulatory functions, remain similar

The two genomic *Parasponia* haemoglobin DNA sequences contain three introns (Figs 3 and 4) which are at the same positions as those in the leghaemoglobin genes Introns 2 and 3 are inserted between codons, intron 1 splits a codon after its second base in *Parasponia*, as in the leghaemoglobins[3-5] and in the vertebrate globins[14,15] The central intron is unique to the plant haemoglobins[3-5,14,16] The conservation of these intron positions in legumes and a non-legume plant indicates a common origin for plant haemoglobins from an ancestral functional gene unit having three introns Gō suggested[17], on the basis of protein domain analysis, that a third central intron would also have been present in the putative ancestor of animal globins

In contrast with the haemoglobin multigene families found in legume plants[3], Southern blot analyses of *Parasponia* genomic DNA indicate there is only one haemoglobin gene locus A single band appears in digests with *Bam*HI (13 kb), *Eco*RI (7 kb), *Hin*dIII (9 kb) and *Bgl* II (8 5 kb) with pL209 as probe However, two different haemoglobin clones were isolated from both cDNA and genomic DNA The clones differ at four nucleotide positions in the coding region, two of which led to an amino-acid change, and by a few bases in introns 1 and 2 (see Fig 3) Intron 1 has 122 nucleotides in both genomic clones, intron 2 has 326 or 334 nucleotides and intron 3 is 159 nucleotides long With the exception of a single base the clones are identical over at least 300 base pairs (bp) upstream and downstream in the non-translated sequences These data suggest the existence of allelic heterogeneity at a single locus rather than different genes The fact that *Parasponia* has not developed a multigene haemoglobin family as in the legumes, and that *Parasponia* haemoglobin has an unusually long polypeptide chain may reflect a relatively primitive haemoglobin gene condition[18]

Legume and *Parasponia* haemoglobins both have around 15% protein homology with animal globins and introns 1 and 3 in plant haemoglobins are at positions identical to the introns in vertebrate globins A monophyletic origin of all plant and animal haemoglobins and their vertical evolution seems probable The invocation of horizontal gene transfer[3] between animals and plants appears to be unnecessary but if it occurred it is likely that it predates the diversification of angiosperm plants[19] A presumptive common ancestor of animal and plant haemoglobins could date back 1,500 million years, before the time of the radiation of animals and plants[20]

The *Parasponia* haemoglobin cDNA probe hybridizes to haemoglobin genes in the distantly-related *Casuarina*, which

Fig. 4 Comparison of the coding regions of the *P andersonii* haemoglobin gene (sequence indicated is pL209/305, deviations seen in pL201/401 above the sequence) with those of kidney bean haemoglobin[5] Spaces in these regions indicate identity of leghaemoglobin nucleotide sequence to *Parasponia* The kidney bean introns (↔) are different in length, very low in homology and are not compared The same applies to the 5′ and 3′ untranslated regions Also indicated are the positions of oligonucleotides used in cDNA clone identification (14 mer mixture CTC/TTACTTTTTGCG, 17mer mixture TTC/TAAGCTTTACTTTTGG) The derived (and corrected with respect to ref 9) *P andersonii* haemoglobin I amino-acid sequence is given in the bottom line S_1 indicates mapped start of transcription Presumptive promoter elements are underlined (- - - -)

Methods. DNA sequencing was according to Messing[24] following subcloning of appropriate fragments into M13 mp phages Sites used for subcloning of cDNA clones were *Pst*I and *Sau*3A, and for genomic clones were *Eco*RI, *Hpa*I, *Bcl*I and *Sca*I Synthetic oligonucleotides were made to facilitate sequencing of IVS-2 from both strands The DNA sequences of pL201, pL209, pL305 and pL401 were determined at least twice from different M13 mp subclones

has a nitrogen-fixing symbiotic association with *Frankia*, an actinomycete[7] As *Parasponia* is symbiotically associated with *Rhizobium*, this degree of haemoglobin homology suggests separate evolution of plant haemoglobins and nitrogen-fixing symbioses We have also examined DNA from the genus *Trema* (Ulmaceae)[21], a non-nodulating close relative of *Parasponia* The *Parasponia* cDNA probe detects a related sequence in *Trema* at high stringency hybridization conditions, sequence analysis will indicate whether this represents a homologous haemoglobin gene and whether the gene is potentially functional Perhaps haemoglobin genes have survived because of cryptic expression in non-symbiotic tissue in all plants, with abundant expression only in the N_2-fixing nodules of relatively few species scattered through different plant families

We thank Ms G Koci and Ms J Norman for technical assistance, Dr M J Trinick for his supply of nodulated *Parasponia* seedlings, Dr B Barlow for his advice in designing Fig 1 and Drs A and K Marcker for fruitful discussions

New Books
from
CROOM HELM

■ COMPUTER GRAPHICS IN BIOLOGY
Robert Ransom and Raymond Matela, Department of Biology, The Open University
Reviews the uses of computer graphics in teaching, simulation work, and as a tool for analysis and examination of results It considers general methodologies and specific applications such as in neurobiology and molecular modelling
£25 00 hbk 0-7099-4106-4 250 pages September 86

■ DATING AND AGE DETERMINATION OF BIOLOGICAL MATERIALS
Edited by Michael R Zimmerman, Coney Island Hospital, New York, and J Lawrence Angel, Smithsonian Institution, Washington DC
Considers the methods available for determining the age of biological materials in the context of medicine, biology, earth sciences, palaeontology, archaeology and anthropology
£45 00 hbk 0-7099-0470-3 304 pages June 86

■ MODELLING IN BEHAVIOURAL ECOLOGY
Dennis Lendrem, Department of Psychology, University of Newcastle-upon-Tyne
Describes models of animal behaviour and outlines how the modellers came to frame their problem in mathematical form Aimed at the advanced student in ecology and behaviour
£25 00 hbk 0-7099-1691-4 250 pages October 86
£12 95 pbk 0-7099-4119-6

■ ECONOMIC AND APPLIED GEOLOGY
W G Shackleton, South Australian College of Advanced Education
This book provides an excellent general introduction to the subject for undergraduate students of geology, geophysics, mining geology and for civil engineers
£19 95 hbk 0-7099-3387-3 256 pages September 86
£ 8 95 pbk 0-7099-4440-3

■ THE BEHAVIOUR OF TELEOST FISHES
Edited by Tony J Pitcher, School of Animal Biology, University College of North Wales
Reviews major topics in fish behaviour, ranging from genetic and motivational inputs to behaviour, to sensory modalities, behavioural ecology and individual species studies
£42 50 hbk 0-7099-2070-9 560 pages January 86

■ A FUNCTIONAL BIOLOGY OF MARINE GASTROPODS
Roger N Hughes, School of Animal Biology, University College of North Wales, Bangor
'succeeds in portraying much of the excitement of the recent work that has been carried out within the field it can be warmly recommended to all those with more than a passing interest in molluscs and especially those persons running courses on the evolutionary biology of invertebrates' *Times Higher Education Supplement*
£25 00 hbk 0-7099-3746-6 256 pages February 86

■ FEEDBACK AND MOTOR CONTROL IN INVERTEBRATES AND VERTEBRATES
Edited by W J P Barnes, Department of Zoology, and Margaret Gladden, Institute of Physiology, University of Glasgow
Brings together the fields of invertebrate and vertebrate neurobiology and should interest zoologists and physiologists
£40 00 0-7099-32774 480 pages December 85

■ GENE MANIPULATION AND EXPRESSION
Edited by Robert E Glass University of Nottingham and Jaroslav Spizek Czechoslovakian Academy Prague
Presents selected papers from a symposium held in 1984 in Czechoslovakia It covers rearrangement of genetic material and DNA cloning vectors, RNA polymerase, the role of cyclic AMP in gene expression, and translational control
£45 00 hbk 0-7099-3818-7 576 pages January 86

■ GRAZING IN TEMPERATE ECOSYSTEMS: LARGE HERBIVORES AND THE ECOLOGY OF THE NEW FOREST
R J Putman, Department of Biology, University of Southampton
This book combines a general review of our knowledge of the ecology of the New Forest with original research which shows the effects of continued heavy grazing on a temperate ecosystem
£17 95 hbk 0-7099-4036-X 200 pages May 86

■ THE SOCIOBIOLOGY OF ETHNOCENTRISM: EVOLUTIONARY DIMENSIONS OF XENOPHOBIA, DISCRIMINATION, RACISM AND NATIONALISM
Edited by Vernon Reynolds, University of Oxford Vincent Falger University of Utrecht and Ian Vine, University of Bradford, for the European Sociobiological Society
Presents sociobiological studies which focus on the topic of in-group/out-group behaviour
£27 50 0-7099-4222-2 336 pages November 86

■ FISH PHYSIOLOGY: RECENT ADVANCES
Edited by Stefan Nilsson and Suzanne Holmgren, University of Goteborg Sweden
Reviews a number of major advances including physiology of the circulation digestive physiology and physiological toxicology
£27 50 0-7099-1837-2 224 pages July 86

■ A FUNCTIONAL BIOLOGY OF NEMATODES
David A Wharton, Department of Zoology, University of Otago New Zealand
Shows how the basic body plan and life cycle of nematodes has evolved to enable them to exploit a wide range of environments It looks at the phylum as a whole from the viewpoint of intervertebrate physiology, ecology and evolution
£19 95 hbk 0-7099-3602-8 208 pages May 86

■ GULLS AND PLOVERS: THE ECOLOGY AND BEHAVIOUR OF MIXED-SPECIES FEEDING GROUPS
C J Barnard, University of Nottingham and D B A Thompson University of Liverpool
' there is much interesting new detail in the book and some new ways of looking at the interrelationships of flocking and foraging strategies' Nature
£25 00 hbk 0-7099-3230-8 320 pages September 85

■ THE LEAD DEBATE: THE ENVIRONMENT, TOXICOLOGY AND CHILD HEALTH
Edited by Richard Lansdown Chief Psychologist Hospitals for Sick Children London, and William Yule Department of Psychology Institute of Psychiatry London
' the contributors have collected a lot of extremely useful scientific information an important and useful interdisciplinary review Nature
£25 00 hbk 0-7099-1653-1 304 pages April 86
£14 95 pbk 0-7099-1654-X

NEW BOOK

The Particle Explosion

Frank Close and Christine Sutton

This is a spectacular illustrated journey into the subatomic world discovered by physicists during the last hundred years It is the first major illustrated book on particle physics
0 19 851965 6, 240 pp , illus , January 1987 £15

Concepts of Particle Physics: Volume Two

Kurt Gottfried and Victor F. Weisskopf

This authoritative work retraces the material outlined in the first volume, but in far greater detail and with a much higher degree of sophistication
0 19 503393 0, 352 pp , illus , OUP USA, February 1987 £35

Concepts of Particle Physics: Volume One

New in Paperback

Kurt Gottfried and Victor F. Weisskopf

'A splendid review of subnuclear phenomena provides a sophisticated overview without a welter of details
Physics Today on the hardback edition
0 19 504373 1, 180 pp , illus , OUP USA, 1986, paperback £9 95

An Introduction to Liquid Helium

Second edition

J. Wilks and D. S. Betts

The second edition, building strongly on the 1970 edition, brings the reader up to date on liquid ^{4}He, liquid ^{3}He, and mixtures
0 19 851471 9, 180 pp , illus , Clarendon Press, January 1987 £19 95

Theory of Neutron Scattering from Condensed Matter

Volumes 1 and 2

New in Paperback

Stephen W. Lovesey

'Stephen Lovesey has again provided us with a very useful work of reference will be consulted by neutron scatterers for many years'
Nature on the hardback edition
International Series of Monographs on Physics
Volume 1 0 19 852028 X, 352 pp , illus , Clarendon Press, 1986, paperback £17 50
Volume 2 0 19 852029 8, 360 pp , illus , Clarendon Press, 1986, paperback £17 50

The Biological Chemistry of Marine Copepods

Edited by E. D. S. Corner and S. C. M. O'Hara

This is the first book to deal specifically with this topic It is essentially a collection of critical reviews outlining the present state of knowledge and indicating future developments
0 19 854714 5, 360 pp , illus , Clarendon Press, November 1986 £40

The Physics of Semiconductor Devices

Fourth edition

D. A. Fraser

'It is clearly written and is up-to-date I can thoroughly recommend this work' **The Australian Physicist** on the third edition
Oxford Physics Series
0 19 851867 6, 208 pp , illus , Clarendon Press, 1986 £20
0 19 851866 8, paperback £9 95

Principles of Nuclear Magnetic Resonance in One and Two Dimensions

Richard R. Ernst, Geoffrey Bodenhausen, and Alexander Wokaun

A unified view of modern NMR spectroscopy, covering basic principles and techniques for the study of solutions and solids
International Series of Monographs on Chemistry 14
0 19 855629 2, 640 pp , illus , Clarendon Press, November 1986 £60

Patents in Chemistry and Biotechnology

Philip W. Grubb

A new edition of *Patents for Chemists* (OUP 1982) This book guides the lay reader through the complexities of the British, European, and US patent systems
0 19 855222 X, 352 pp , illus , Clarendon Press, November 1986 £25
0 19 855221 1, paperback £12 50

The Thermodynamics and Gas Dynamics of Internal-Combustion Engines

Volume 2

Edited by J. H. Horlock and D. E. Winterbone

A collection of chapters contributed by leading authorities in the field to the memory of R S Benson, author of Volume 1 It is the most comprehensive analytical text available in this subject area
0 19 856212 8, 688 pp , illus , Clarendon Press, November 1986 £75

Nonlinear Ordinary Differential Equations

Second edition

D. W. Jordan and P. Smith

'It is well written, well motivated and contains some recent developments of interest which have not been readily accessible before at this level' **Mathematical Reviews** on the first edition
Oxford Applied Mathematics and Computing Science Series
0 19 859657 X, 400 pp , illus , Clarendon Press, December 1986 £27 50
0 19 859656 1, paperback £14 50

NEW BOOKS

Probability: An Introduction

Geoffrey Grimmett and Dominic Welsh

A concise introduction to probability and random processes at the university level
0 19 853272 5, 224 pp , illus , Clarendon Press, 1986 £20
0 19 853264 4, paperback £9 95

Matrices for Statistics

M. J. R. Healy

This book is intended to cover the necessary ground as briefly as possible Only the simplest of basic mathematics is used Numerical methods for matrices are described
0 19 852207 X, 100 pp , illus , Clarendon Press, November 1986 £12 50

Supercomputers and Their Use

Christopher Lazou

Written in an informal style, this book is aimed at a general, computer literate audience Technical details are kept to a minimum, and are clearly explained whenever they are unavoidable
0 19 853720 4, 240 pp , illus , Clarendon Press, November 1986 £22 50

Subnormal Subgroups of Groups

John C. Lennox and Stewart E. Stonehewer

The object of this book is to give a comprehensive account of subnormal subgroups of both finite and infinite groups, from the early work of Wielandt, to very recent results relating to the elusive submoralizer of a subgroup
Oxford Mathematical Monographs
0 19 853552 X, 320 pp , illus , Clarendon Press, December 1986 £35

Undergraduate Algebra: A First Course

C. W. Norman

The aim of this book is to make the first year student feel thoroughly at home with the theory of rings, fields and vector spaces and especially with the techniques of matrix manipulation
0 19 853249 0, 432 pp , illus , Clarendon Press, 1986 £30
0 19 853248 2, paperback £15

The NAG Library: A Beginner's Guide

Jen Phillips

The aim of this book is two-fold It provides alternative descriptions of a basic selection of NAG routines Secondly, it aims to act as a guide to how a newcomer should approach the *Library*
0 19 853263 6, 256 pp , illus , Clarendon Press, December 1986 £20

Loop Groups

Andrew Pressley and Graeme Segal

A complete and self-contained account of what is known about the subject written from a geometrical and analytical point of view, with quantum field theory very much in mind
Oxford Mathematical Monographs
0 19 853535 X, 328 pp , Clarendon Press, November 1986 £40

Cytogenetics of Mammalian Embryonic Development

A. P. Dyban and V. S. Baranov

A comprehensive review of the role that chromosomes play in normal and abnormal embryonic development
0 19 854584 3, 280 pp , illus , Clarendon Press, December 1986 £35

Blindsight: A Case Study and Implications

L. Weiskrantz

An account of research over a number of years into a particular case of blindsight
Oxford Psychology Series No 12
0 19 852129 4, 200 pp , illus , Clarendon Press, 1986 £19 50

Perception and Communication

New in paperback

D. E. Broadbent

First published in 1958, this book has become recognized as a classic in its field Professor Posner has written a Foreword for this reissue
0 19 852171 5, 352 pp , illus , 1986, paperback £15

The Neuropsychology of Anxiety

New in paperback

J. A. Gray

'The book deserves to be read by all those who are interested in extending neurology into psychiatry'
British Medical Journal on the hardback edition
Oxford Psychology Series
0 19 852127 8, 500 pp , illus , Clarendon Press, December 1986, paperback £15

The Handbook of Ecological Monitoring

Edited by R. Clarke

Written by twelve of the world's experts on ecological monitoring, this book will provide an invaluable introduction to the subject for those requiring a bird's-eye view of the technologies now available
0 19 854590 8, 320 pp , illus , November 1986 £30

Immune Mechanisms in Invertebrate Vectors

Edited by Ann M. Lackie

This volume describes recent ideas and information on methods of recognition and mechanisms of response in the immune systems of insects, crustacea and molluscs
Symposia of the Zoological Society of London No 56
0 19 854004 3, 304 pp , illus , Clarendon Press, November 1986 £40

NMR OF PROTEINS AND NUCLEIC ACIDS

by **K. Wuthrich,** *Institut fur Molekularbiologie und Biophysik, Zurich, Switzerland*

This comprehensive introduction to both underlying principle and experimental procedures, covers the structure and NMR of biopolymers, including 2D NMR and Nuclear Overhauser effects, resonance assignments and structure determination in proteins, and resonance assignments and structure determination in nucleic acids. Also provided is an up-to-date account of NMR studies for chemists, biochemists, biophysicists and molecular biologists concerned with structure and function of proteins and nucleic acids. The book will enable specialists and non-specialists to evaluate the potentialities and limitations of the method.

0471 82893 9 310pp October'86 £44.60

NATURAL HISTORY OF THE MAJOR HISTOCOMPATIBILITY COMPLEX

by **J. Klein**

This work is a natural history of the major histocompatibility complex written for anyone who is working on the MHC but wants to step back and review the complex in its entirety, for anyone who wants to be introduced to the MHC, or for anyone who is just curious about this much talked-about chromosomal region. By 'natural history' is meant an all encompassing treatment of the MHC, both human and mouse, in its entire range and its details — but presented in a way that anybody can understand without consulting a variety of other sources. Most of the details are summarized in the form of tables whereas the text concentrates on generalizations and discussions.

0471 80953 5 798pp October'86 £90.75

AGE AND SUSCEPTIBILITY TO TOXIC SUBSTANCES

by **E.J. Calabrese,** *Division of Public Health, University of Massachusetts, USA*

Differential susceptibility to pollutant and drug toxicity is a major area of public health concern today. If adverse effects can be prevented from occurring in the high-risk segments, it follows that the general population will also be protected. The causes of differential susceptibility include age, sex, genetic background, nutritional status, the presence of pre-existing diseases, and lifestyle. Previous books by the author have addressed various aspects of these host factors. The present book complements the previous efforts by addressing the age factor in the course of environmental-induced disease.

Series Environmental Science and Technology

0471 84366 0 314pp October'86 £62.25

ECOSYSTEM THEORY AND APPLICATION

edited by **N. Polunin**

The term ecosystem has been widely used, often in a confusing manner since it was first coined some 50 years ago. This book uses the term in the way it was originally defined, as a means of describing the biota which live together as a social unit and also the inorganic and dead parts of the system. Topics covered include arctic desert, marine and tropical ecosystems, their dynamics and structure, economics, evolution and ecological phenomena.

0471 10274 1 462pp August'86 £49.95

SPECTROSCOPY OF BIOLOGICAL SYSTEMS

edited by **R.J.H. Clark,** *University College London* and **R.E. Hester,** *University of York*

This is the first volume of this well-established series, formerly entitled "Advances in Infrared and Raman Spectroscopy", to be devoted to a single theme. The major objectives of the series remain unchanged, ie to integrate theory and practice and to bring together different branches of research in both the academic and industrial spheres through the presentation of critical review articles in fundamental and applied spectroscopy. But its scope has simultaneously been widened beyond the confines of infrared and Raman spectroscopy and focused down more sharply to a well-defined subject area of great current interest. Biological systems represent such an area for applied spectroscopy.

Series Advances in Spectroscopy, Volume 13

0471 90978 5 570pp September'86 £83.00

CALCIUM OF THE CELL

Ciba Foundation Symposium 122

Chairman **P. Baker,** *Department of Physiology, King's College, London*

This international symposium deals with the central role of calcium in intracellular processes that range from muscle contraction to enzyme activation, exocytosis, cell proliferation, and early embryonic development. The symposium should interest research workers in cell biology, cell physiology and molecular biology, it is also relevant to pharmacologists, neurophysiologists and endocrinologists who are concerned with fundamental cell regulatory processes.

Series Ciba Foundation Symposium

0471 91088 0 310pp September'86 £27.50

FOLATES AND PTERINS

Volume 3: Nutritional, Pharmacological and Physiological Aspects

edited by **R.L. Blakley,** *St Jude Children's Research Hospital* and **V.M. Whitehead,** *Montreal Children's Hospital*

This is the first comprehensive review of folates in fifteen years. The contributions to the book provide up-to-date accounts of folate metabolism and chemistry, explaining the metabolic basis for many forms of anemia and providing the basis for understanding the action of certain anticancer drugs, and detail the enzyme targets of some drugs used in treating cancer.

Series Folates and Pterins

0471 81212 9 496pp October'86 £95.45

FUSARIUM SPECIES

Their Biology and Toxicology

by **A.Z. Joffe,** *Hebrew University, Israel*

This clear, in-depth guide describes the Fusarium genus and its toxins — a group of plant pathogens associated with fatal outbreaks of alimentary toxic Aleukia disease in man, and implicated as the active agent in "yellow rain". Noted authority Abraham Joffe presents new and original research into the chemistry, biochemical and toxicological properties, and effects of the four major groups of fusariotoxins. Trichothecenes and Zearalenone and their derivatives, Moniliformin and Butenolide.

Study in indifference

Is the British public not interested in science books? Or is it being poorly served by the review media? John Manger of Oxford University Press on the trans-Atlantic contrasts in the reception accorded to a biography of Albert Einstein.

In 1982 Oxford University Press published *'Subtle is the Lord' ...The Science and the Life of Albert Einstein,* by Abraham Pais. It was judged to be, and remains, a superb piece of scholarship, but not without its problems. Why another Einstein book, asked the doubters, and so soon after the centenary celebration in 1979? We took the plunge anyway, in the belief that we had a truly original and saleable book on our hands. So it turned out to be. Over the next year or so over 30,000 hardback copies were bought world-wide, and subsequently a comparable number of copies of the paperback. The distribution of sales, and how the book was treated by the respective review media in Britain and the United States is illuminating.

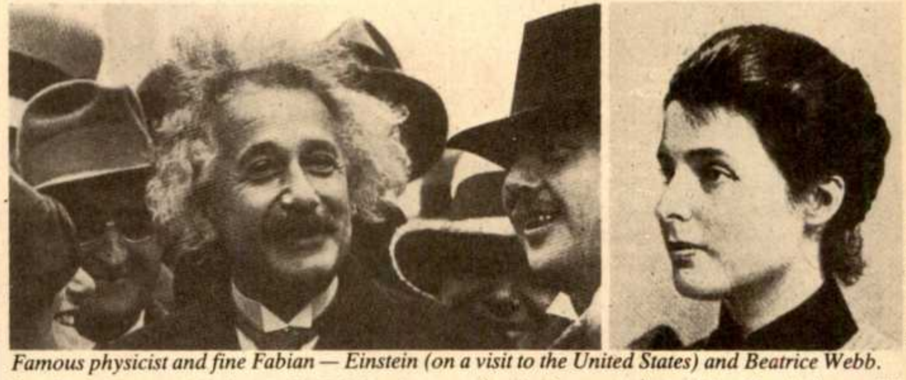
Of the hardbacks, more than 25,000 were sold in the United States, the remainder in the rest of the world, about 2,500 of them in Britain. To put these figures in perspective, an average scholarly physics monograph would be expected to sell 1,000–1,500 copies in hardback world-wide, and more often than not would not be published in paperback. Most new novels sell far fewer than 30,000 copies in hardback.

On both sides of the Atlantic, science magazines and those publications largely or completely devoted to reviews did well by the book. In the United States it was reviewed by *The New York Review of Books, Science, Physics Today, Scientific American* and numerous other weeklies and journals; in Britain by *The Times Literary Supplement, The Times Higher Educational Supplement, Nature* and *New Scientist.*

In the United States, however, the book also attracted much wider attention — from *The New York Times, Los Angeles Times* and *Christian Science Monitor*, as well as from some 30 newspapers across the nation, ranging from the Youngstown (Ohio) *Vindicator* to the Phoenix (Arizona) *Republic*. The review in *The New York Times* was the lead, with picture, in the Sunday books section, perhaps the prime review position in the world. Booksellers, too, were enthusiastic in setting up window displays, while a science book club initially took several thousand copies and then came back for more.

None of the above publicity was particularly exceptional for an American trade publishing house. What was exceptional was the willingness of review editors in such a wide variety of newspapers and magazines to devote space to such a book. It was, after all, not a simple layperson's guide to Einstein, but a scholarly, yet readable, account of the man and his not very simple science.

The book's reception by the "general" media in Britain was in stark contrast. Our approaches to the national weeklies and dailies for review coverage were, in general, met with bewilderment: "Science? We don't have anyone who can review science books"; or "Our readers aren't interested in science"; or "We have 20,000 books a year submitted to us for review, we can't cover them all, you know". The only national newspaper review appeared in *The Observer*, 17 column inches of it. Otherwise, except for BBC coverage in *Kaleidoscope* and on the World Service, the book was virtually ignored. There were no book club sales (there is no scientific book club in Britain).



Famous physicist and fine Fabian — Einstein (on a visit to the United States) and Beatrice Webb.

Mansell Collection

Two questions arise from this experience. Is the British public not interested in science books? Or is it being poorly served by the review media? Bearing on the first of these is the existence in the United States of the well-known and popular "Physics for Poets" course. Students from most disciplines are encouraged to take at least one science option, and physics "without the sums" is widely taught. Stimulating textbooks are produced in large quantities by college publishers and the end result is a sizeable population of students who have a knowledge of space, time, the nature of the Universe, the atom, crystal structure and, yes, even relativity. More importantly, individuals are not encouraged to think it is somehow smart to be scientifically illiterate.

They will certainly also have an awareness of the importance of a character such as Einstein. One of the more amusing responses to our attempts to attract attention to Pais's book was "Well you'd expect the Americans to be interested in Einstein, but he's not really very big over here". Who is big over here? In the week we would have expected reviews of *'Subtle is the Lord'* the dailies and weeklies were obsessed (in terms of review space) by a volume of the diaries of Beatrice Webb. Many column inches, plus suitable period photographs, were devoted to the earnest, but ultimately trivial, meanderings of this fine Fabian. In the great scheme of things, it is difficult to believe that Einstein is not a more important figure to more people, even in Britain, than Beatrice Webb.

The literary editor would doubtless discount this as a somewhat tendentious conclusion, and retort that these kinds of judgements cannot and should not be made when it comes to deciding which books are reviewed in the national press. A literary editor must do what is best for circulation — quite right. But is it a valid assumption that 99 per cent of the readers of the daily and weekly papers have no interest in science for 99 per cent of the time? Because that is the legitimate conclusion to be drawn from the amount of review space given to science books. It should not be forgotten that not only have the social implications of science never been greater, but that there are hundreds of thousands of practising scientists in Britain some of whom can even read newspapers.

Per head of population, the biography of Einstein sold twice as well in the United States as it did in Britain. But it is nonetheless almost certainly true that there is a greater interest in science in Britain than the media lead themselves to believe. The worrying corollary of their indifference (or plain ignorance) is that publishers will tend to take fewer risks, look for fewer new authors and develop fewer new talents if they feel that science books will be "published without trace". The example of Pais's book demonstrates that science books do not have to be trivial to be saleable in global terms. The pity of it is that the review media in Britain remain stubbornly resistant to educating themselves or their readers. □

John Manger is Editorial Director responsible for science and medicine at Clarendon Press, an imprint of Oxford University Press, Walton Street, Oxford OX2 6DP, UK.

One-eyed darwinism

Philip Kitcher

The Blind Watchmaker. By Richard Dawkins. *Longman: 1986. Pp. 332. £12.95. To be published in the United States on 24 November by W.W. Norton, $18.95.*

To Richard Dawkins it is always *the* problem. How are we to account for the complex design in nature, the intricacy of fit between organism and environment that once moved William Paley to propose the analogy of finding a watch on the beach, and thereupon build an argument for the existence of a Creator? Dawkins admires Paley's appreciation of a great mystery, even though he has no sympathy for Paley's theological solution. Thanks to Darwin, we have no need of that hypothesis. The preordained unfolding of the Creator's plan is replaced by the action of natural selection, the blind watchmaker of Dawkins's title.

Dawkins believes, with considerable justice, that the theory of evolution by natural selection is widely misunderstood, and part of his project is to explain that theory in a manner that will demonstrate its power to solve Paley's puzzle. *The Blind Watchmaker* contains passages of exposition that deserve sustained applause. The third chapter begins by distinguishing clearly between single-step selection and cumulative selection, and proceeds through some ingenious and illuminating computer simulations which make plain how cumulative selection can give rise to striking and unanticipated modifications of an original form. It is tempting to suggest that Dawkins's program should be made widely available, to schoolchildren and to eminent astrophysicists, so that the rumbling complaint that compares the effects of selection to a tornado sweeping through a junkyard may finally be laid to rest.

No less brilliant is the discussion at the end of Chapter 4, in which Dawkins the sensitive naturalist replaces Dawkins the clever computer hacker. In 15 pages, he reviews the standard examples of convergent evolution (and some lesser known cases) in prose that makes them extraordinarily vivid. Chapter 5 provides a clear and entertaining account of the elements of contemporary genetics, and Chapter 6 an outline of Cairns-Smith's hypothesis about the origins of life and a useful response to those who claim that the occurrence of life on our planet is so improbable that it signals a miracle. The next two chapters reveal the ways in which natural selection can work constructively to yield "a building up of complexity that has more in common with addition than with subtraction" (p.169). Particularly admirable is Dawkins's lucid presentation of Lande's complex ideas about runaway sexual selection, a discussion in which Dawkins was assisted by Alan Grafen.

The six central chapters of *The Blind Watchmaker* thus constitute a compelling exposition of the main themes of contemporary neo-darwinism, indeed the most compelling presentation of those themes that I know. The stylistic talents that won a broad readership for *The Selfish Gene* are fully in evidence here. But Dawkins aims not only to present what is uncontroversial amongst evolutionary biologists but also to take a stand on matters that continue to spark professional debate. In the end, *The Blind Watchmaker* tries to articulate a particular version of neo-darwinism, and in this part of his enterprise Dawkins is far less successful.

The last three chapters take up three main areas of disagreement in contemporary evolutionary theory. Dawkins considers the proposal that the theory of punctuated equilibria provides an expansion of neo-darwinism, the continuing controversies in systematics, and an assortment of positions that emphasize alternatives to selection as agents of evolutionary change. In this part of the book the real issues are never joined. Dawkins sees clearly that some of the most strident criticisms of neo-darwinism caricature the position that they advertise themselves as attacking. But his own defence is to identify untenable extremes and to portray the version of neo-darwinism that he favours as occupying the sensible middle ground.

I will concentrate on Dawkins's attempt to deflate the punctuationist challenge to neo-darwinism. His strategy here is to analyse the three main claims advanced by the punctuationists, showing that, under analysis, Gould, Eldredge, Stanley and others do not stray very far from neo-darwinian orthodoxy. The success of this strategy depends on how far the analysis proceeds. Eldredge and Gould made a proposal about the geometry of phylogenetic trees: evolution consists of long periods of stasis punctuated by short bursts of speciation. Dawkins fastens on the idea that speciation occurs "suddenly", and argues that the rates envisaged are consonant with those admitted by gradualists. But this is to bypass the main point of difference. Punctuationists contend that evolutionary changes are concentrated around episodes of speciation, and they are (to say the least) sceptical about the importance of either morphological change or speciation within unbroken lineages.

In discussing punctuationist claims about the mechanisms underlying stasis and speciation, Dawkins also finds only what is orthodox. The idea that small molecular substitutions may have large phenotypic effects is, he claims, a part of mainstream neo-darwinism. Thus, the punctuationist emphasis on the importance of modified developmental pathways in speciation can be assimilated into the reigning orthodoxy. The issue here is closely related to that in the chapter where Dawkins considers the complaint that neo-darwinians overemphasize the importance of natural selection in evolution and fail to appreciate the role of developmental constraints.

There, Dawkins concludes by claiming that "all serious Darwinians" would agree that "we can't afford to ignore the constraints on evolution that embryology imposes" (p.311). But although, like Dawkins, most neo-darwinians are now prepared to declare that the power of selection to shape a phenotypic trait is limited by developmental factors, the critics of orthodox neo-darwinism argue that in practice this declaration is forgotten and that explanations of phenotypic traits effectively suppose that natural selection is omnipotent. The debate should centre not on the extreme "Mutationist" who figures in Dawkins's pages, but on the relative importance of various agents of evolutionary change.

Dawkins's failure to identify the real question in this case is reflected in a failure to deal adequately with the punctuationists' account of stasis, and he is led to canvass extraordinary possibilities in interpreting their views. Allegedly, punctuationists believe that species "actively resist change" (p.247), and Dawkins has little trouble in rebutting one obvious reading of this phrase. Charity easily finds alternative interpretations. If there are indeed strong developmental constraints, then throughout most of the history of a species there may be very few options to exercise selection. Only when the environment changes radically, disrupting the mechanisms that typically buffer ontogenesis, will hitherto cryptic variation become apparent and will there be a possibility for evolutionary experimentation. Whether or not scenarios of this kind prevail in the history of life, the claim that they do represents an important challenge to the vision of stately unfolding that permeates orthodox neo-darwinism.

Dawkins's discussion of the third plank in the punctuationists' platform, the thesis that many macroevolutionary trends are the result of processes of species selection, is extremely brief, and the brevity is significant. Instead of presenting his reasons for thinking that species selection is not very important in evolution, Dawkins refers the reader to his previous book, *The Extended Phenotype*. This was a wise decision that would have been advisable at many other places in the last three chapters of *The Blind Watchmaker*, for *The Extended Phenotype* treats the leading controversies in a far more satisfying way than does the new book. However Dawkins does add to his reference another argument that is in tune with the main theme of *The Blind Watchmaker*. Species selection, he contends, cannot account for complex adaptations.

At this point, the sources of the successes and the shortcomings of *The Blind Watchmaker* click into place. Punctuationists will want to combat the argument, alluded to but not presented, for the thesis that species selection is unimportant in evolution, but they may be quite unworried by the charge that species selection cannot account for complex adaptations. Part of their case is that the prevalence of complex adaptations in the history of life has been exaggerated by orthodox neo-darwinians. *The Blind Watchmaker*, which makes the explanation of complex adaptations central to the neo-darwinian enterprise, sets up from the beginning a framework in which the character of the interesting debates within contemporary evolutionary theory cannot be made clear.

The book starts with an attempt to present Paley's puzzle. Dawkins would like his readers to feel the grip of the problem of explaining organic complexity, and he would like to present that problem in a way that does not prefigure the darwinian solution. But how exactly is the notion of a well-designed, complex object to be characterized? Dawkins displays great ingenuity in his effort to avoid the trivializing answer that explicitly defines a complex adaptation as the product of a history of selection. For those who view neo-darwinism as flawed by its overemphasis on adaptation, his struggles are likely to seem hopeless. They will suggest that the problem is to define a class which will turn out to include just those traits whose presence is to be understood in terms of a history of individual selection without making use of ideas that would have been unavailable to Paley (or any other pre-darwinian impressed with the apparent design of organisms). But, claim the anti-adaptationists, cases of apparent design are a motley. Some, but by no means all of them, are to be understood in terms of the action of individual selection. Only by introducing the concept of selection explicitly into our characterization of the class of "well-designed complex objects" can we manage to present Paley's problem in a way that allows for Dawkins's preferred darwinian solution. Hence, Dawkins's emphasis on the evolutionary explanation of "complexity" disguises an unargued commitment to the view that the problem of adaptation is central to evolutionary theory, and a corresponding slighting of important alternatives. For Richard Dawkins — but not for all sophisticated evolutionists and, arguably, not for Darwin — it is always *the* problem.

For all my reservations, I am confident that *The Blind Watchmaker* will do much good. At its heart is a remarkable account of some of the most important ideas in the history of science. Dawkins should clear up many more misapprehensions than he fosters, and his readers should gain a sense of the excitement of contemporary evolutionary biology. If they are moved to read further, then their initial acquisition of prejudices is likely to be corrected. The details, we may hope, will come later. ☐

Mammal Evolution: an illustrated guide
R.J.G. Savage & M.R. Long
Unique colour restorations and other illustrative material combine with Professor Savage's authoritative text to provide a wide-ranging study of these diverse animals.
256pp, 120 colour, 120 b/w illustrations, 300 line drawings.
Hbk. 0 565 00942 7 **£17.50**

The Ancestry of The Vertebrates
R.P.S. Jefferies
The problem of the origin of the vertebrates is solved by deriving them from calcichordates, fossils found in marine rocks of Cambrian to Devonian age.
300pp, 300 b/w illustrations.
Hbk. 0 565 00887 0 **£50.00**

A Manual of Forensic Entomology
K.G.V. Smith
An important new book in this neglected area of entomology. Will be of use to forensic scientists, ecologists and archaeologists.
256pp, 402 figs.
Hbk. 0 565 00990 7 **£17.50**

Jobling's Anatomical Drawings of Biting Flies
Ed. D.J. Lewis
356 of Boris Jobling's drawings are published in this volume for the first time, the originals being held by the Wellcome Museum of Medical Science. Will be of particular interest to medical entomologists.
96pp, 96 plates.
Hardback. 0 565 01004 2 **£9.95**

What the scientist has to say

Arthur Kornberg

Storm Over Biology: Essays on Science, Sentiment, and Public Policy. By Bernard D. Davis. *Prometheus, Buffalo, New York: 1986. Pp.324. $22.95.*

SCIENTISTS make poor politicians. They have been self-selected for their interest in things rather than people, and they are generally neither literary nor articulate. They form societies to communicate with one another about their arcane findings but, with some exceptions, they are distinguished from most other professional groups by their social isolation and political innocence.

Were the responsibility of scientists limited to progress in such areas as chess or hieroglyphics, their ineptitude in worldly matters might be tolerated with whimsical affection. But the affairs of government and business, our everyday lives and future depend crucially on science and its technological applications. Must we then rely solely on salesmen, actors and lawyers to make the difficult decisions that require informed judgement about scientific questions? What are we to do?

To compound the problem, the media seem to be entranced by the pronouncements of those who lack scientific knowledge and of a few scientists who have ideological biases and crave publicity. The brushfire controversies over drugs, toxic wastes and genetic engineering have coalesced into wider conflagrations of hostility to all technological, scientific and intellectual effort. Legitimate concern about biological warfare has turned into all-out warfare against biology.

Fortunately there are a few informed and responsible scientists who speak out and write clearly on issues involving biology and society. One such is Bernard D. Davis. In *Storm Over Biology* he has collected together 44 essays and shorter pieces on "science, sentiment and public policy". All but one of these have appeared in print in the past ten years, many in obscure places. Trained as a physician, now a scientist with a distinguished record of administration and of research in biochemistry and microbiology, Davis has intimate knowledge of the difficult issues that he has chosen to confront.

Among the matters that get attention are sociobiology, affirmative action in medical schools and genetic engineering. The common theme underlying all of these topics is the need to build on reality and protect science from politicization by the left or the right. In particular, on the perennial debate over biological versus social determinism ("nature versus nurture"), Davis makes cogent arguments for rigorous studies of human genetics and behaviour against wailings by political ideologues about the potential abuses of new knowledge.

In his discussions of the applications of recombinant DNA technology, Davis speaks from broad experience in microbial physiology, genetics and evolution. Recognizing the legitimacy of concern about the hazards of genetic engineering, he offers convincing arguments for the improbability of the scenarios that have most alarmed the public. He further argues for caution in genetic intervention in man, and for recognizing the limits to the possibilities for such intervention. Against specious attacks by Jeremy Rifkin, recently abetted by the editorial board of *The New York Times*, he takes a bold stand for both truth and reason.

A particularly moving, previously unpublished piece deals with the history of the response to his pleas for balance between affirmative action and maintaining academic standards in medical schools. Davis — a child of immigrants, a witness to anti-Semitism, a perennial fighter for liberal causes and the first department chairman in the history of Harvard University to appoint a black to tenure — cannot be accused of insensitivity to the need for social justice. Yet his editorial in the *New England Journal of Medicine*, arguing for reasonable stretching in increasing the opportunities for minority candidates, was presented by the news media as a racist attack, and he was vilified by many colleagues at Harvard Medical School in the hysterical atmosphere that swept through academic faculties during the late 1960s and early 1970s.

I sometimes wished for the dashes of humour that lace Davis's lectures, but the issues in these essays are really serious business. In his foreword, Edward Shils suggests that scientists generally underestimate the depth of the current anti-science movement, and he makes it clear why this important set of statements by Davis will reward the attention of the general public as well as scientists. ☐

Sigmund meets Charles

John R. Durant

The Problem of Altruism: Freudian–Darwinian Solutions. By C. R. Badcock. *Basil Blackwell: 1986. Pp. 206. £14.95, $24.95.*

BOTH natural and social scientists regard Freud's psychoanalytic theories as a somewhat baroque construction of over-elaborate and largely untestable speculations. *The Problem of Altruism* is dedicated to the task of restoring them to their rightful place in the scientific sun. Christopher Badcock is a social scientist who regards conventional social theories of all sorts as hopelessly inadequate to their task. These theories, he argues, being committed to various forms of "holism" and "cultural determinism", are all involved in the futile attempt to explain one social phenomenon in terms of another. What is needed instead, he suggests, is a reconstruction of sociological theory on more reductionist and individualist foundations, and he attempts to lay these foundations by combining psychoanalysis with darwinian social theory, or human sociobiology.

At first sight, this seems a most unpromising strategy. Not only does human sociobiology have a reputation of its own for over-elaboration and untestability, but also it appears to be quite distinct in its approach to the explanation of behaviour. Where freudian theory deals with psychological entities such as the conscious, the pre-conscious and the unconscious minds, and with psychological processes such as projection, regression and repression, darwinian social theory deals with biological entities such as genotypes and phenotypes, and with biological processes such as kin selection and reciprocal altruism. Where is the room for marriage between these two?

Badcock's central argument is that the place where psychoanalysis and sociobiology meet is in the field of "dynamic psychology". For example, the American sociobiologist Robert Trivers has analysed the relationship between parents and their offspring in terms of psychological conflict; and he has debated the possible adaptive advantages of the unconscious mind. In each case, a recent sociobiological analysis appears to mirror an older, psychoanalytic view. Modern darwinists, Badcock suggests, are busy rediscovering and vindicating Freud.

Badcock builds his case for the rehabilitation of Freud around the central theoretical problem of sociobiology, namely altruism. Sociobiologists admit only two major mechanisms for the evolution of behaviour which raises the reproductive fitness of another individual at the expense of that of the actor: reciprocity, and kin selection. Reciprocity, he suggests, may have become an important element in human social behaviour with the development of cooperative big-game hunting; and it may have led to the rapid evolution of complex psychological mechanisms enabling individuals better to practise and detect cheating, including elaborate moral codes and the unconscious. Similarly, kin selection may have promoted the evolution of a basic psychological mechanism of identification; and once in place, this may have permitted the development of anything and everything from masochism to heroic self-sacrifice on the field of battle.

The strength of this freudian–darwinian approach to human behaviour lies in its recognition of the need for a cogent psychological theory to place between the abstract principles of biology, on the one hand, and the concrete realities of human society, on the other. Its weakness, however, lies in the sloppiness of the theoretical constructs that lie at the heart of darwinized psychoanalysis. Take, for example, the central notion of identification. Supposedly, our ancestors evolved a basic ability to identify with close kin in order that they should aid them in circumstances that would promote their own inclusive fitness. Well and good; but for such an ability to evolve, it is necessary that it should be highly discriminating; for much (indeed, most) helping behaviour is detrimental to inclusive fitness and could never evolve. What we need to know, then, is what kind of identification mechanism is being proposed. This we never learn. Instead, we are presented with an allegedly evolved genetic–psychological trait which is so indiscriminate that it leads people to behave altruistically towards virtually anyone and everyone. Under what circumstances could such a dangerous trait as this possibly evolve?

Psychoanalytic theory has always suffered from the problem that its central claims are insufficiently specified to permit the formulation of scientifically testable predictions. Recently, a certain genre of sociobiological literature has rediscovered the superficial appeal of equally vaguely-formulated hypotheses about the roots of human conduct. Having set out to combine the two enterprises, it is perhaps not surprising that Badcock has fallen victim to the trap of explaining both too little and too much. This is a pity, for the ideal of a powerful and a predictive evolutionary psychology is a worthy one. We know that Darwin's basic insights can be applied rigorously to behaviour in general. Perhaps at least some of Freud's ideas could be re-cast in such a way that they, too, could be applied rigorously to human conduct; but this has yet to be shown. In the meantime it has to be said that no genuine "freudian–darwinian solutions" are to hand. ☐

Scrotum hokum

Walter Gratzer

The Monkey Gland Affair. By David Hamilton. *Chatto & Windus, London: 1986. Pp.155. £11.95.*

ACCORDING to Dr Johnson, a life protracted is protracted woe. In 1953 the good Pope Pius nevertheless journeyed to Switzerland to receive injections of testicular tissue at the hands of the egregious Dr Niehans. His bid for rejuvenation (though presumably not virility, by which it was generally measured) must have been accounted successful, for shortly afterwards the Mephistopheles in this Faustian contract was elevated to membership of the Pontifical Academy. This occurred two years after Serge Voronoff, in his day the most celebrated and successful exponent of testicle (or, as the euphemism of the time had it, monkey gland) implants, had died, discredited, despised and mocked by the society that had lionized him for two decades. Science does not eradicate human credulity, it merely shifts its focus.

The search for the secret of eternal youth has attracted not only crackpots and mountebanks, but also serious and sometimes even distinguished scientists, whose reason could be selectively suspended. The most illustrious of these was Metchnikoff, who was convinced that aging was caused by bacteria in the gut, which destroyed connective tissue. These, he held, could be driven out by abundant ingestion of yoghourt. Examples nearer to our own time include the view that antioxidants can arrest the processes of decline through the elimination of free radicals, and that lead clothing to exclude cosmic radiation will encompass the same end. None of these theories ever achieved much of a popular following; yet in the 1920s one fancies, there must have been queues of rich, aging voluptuaries in the ante-rooms of "Doc" Brinkley's clinic in Kansas and at the Vienna "Vivarium", their trousers draped over their arms, braces dangling, impatiently awaiting their goat testis implants or unilateral vasectomies — which the learned Professor Steinach was able to assure them would result in the retention of sperm in the testis and thus suffusion of the system with youth and vitality. (This is curiously reminiscent of the principle upheld by the yogis, that the emission of sperm, which they equate with manly virtue, enfeebles the body, so that one must learn to aspirate it back after coition. Many Victorian moralists subscribed to the same opinions, but prescribed abstinence as a corrective.) Steinach treated women by the even less appealing method of X-irradiation of the ovaries.

David Hamilton, who is both a surgeon and a historian of medicine, has written a scholarly, absorbing and vivid account of the history of testicular implantation, which thrived in the first half of this century. For Hamilton, the most interesting figure amongst the *galère* of improbable characters that throng his pages is Voronoff, because he was sincere in his efforts, deluded rather than a charlatan, and within limits rational in his beliefs.

These limits were set by an unfathomed though common ignorance, verging on obscurantism, about the techniques of experimental design and evaluation. The same attitudes of mind are still with us, and they animate homeopathy, psychoanalysis and a range of other peripheral disciplines. The reasoning behind implantation therapy was not new, and amounted to little more than that the testis was the seat of fertility, therefore of youth. However the discovery of endocrine secretions encouraged the plausible hope that foreign testicular tissue might be the source of some benign active princi-

The Kansas quack — a feature about "Doc" Brinkley in the New York Evening Journal. *Brinkley is shown holding the first "goat gland baby", born to one of the recipients of a goat testis implant.*

ple. Voronoff became persuaded that a successful xenograft must in general come from a closely related species, not for example from ruminants, and many monkeys were emasculated in the interests of this theory. In the United States prison doctors joined in the game, and were able to go one better: Dr Stanley of San Quentin gaol implanted 30 of his charges with testicles from executed felons and later reported highly satisfactory results from 643 assorted gland transplant operations. All these grafts must of course have been rapidly rejected.

Worse yet was Brinkley, the Kansas quack — unencumbered by any genuine medical qualifications. He chose the goat (an odourless variety), as a species traditionally associated with sexual exuberance, to turn the prematurely enfeebled into satyrs. He and his wife introduced what amounted to a conveyer-belt system of surgery. As a decorative touch, he even injected mercurochrome into the severed end of the vas deferens, to impart a rich colour to the urine and impress the patient. Brinkley owned the hotels that served as convalescent centres, and he set up a radio station to advertise his operation (which was offered in standard and *de luxe* versions), as well as a range of pharmaceutical products. He became extremely rich and popular, and fought a close-run election for State Governor before his luck ran out.

Meanwhile in Paris, Voronoff had married into money on a grand scale and had become a social lion. His second marriage was to a surmised daughter of King Carol of Roumania and the infamous Madame Lupescu. Hamilton makes the point that in the aftermath of the Great War, in which the best had perished and the breeding stock of the upper classes been seriously depleted, and when indeed eugenic theories were widely touted, European society was peculiarly receptive to promises of increased virility and fertility. Voronoff, who was a tireless and prodigiously talented self-publicist, took full advantage of these preoccupations. He also extended his activities to the breeding of sheep, in which he saw great pecuniary promise. The results of Lamarckian (or Lysenkoist) experiments, conducted in Algeria, on the effects of testicular grafts on the performance of rams and the wool-yield of their offspring, were proclaimed a triumph; the British Thoroughbred Breeders Association took fright and announced that grafted racehorses would be struck from the stud-book.

Then Voronoff fell like Lucifer. He was brought down largely through the resolute scepticism of a number of French and English vets, who knew an uncontrolled experiment when they saw one — a circumstance shaming to the medical establishment, which had vacillated feebly throughout Voronoff's years of ascendency. The most tenacious and clear-sighted was Henri Velu, who ran a sheep-breeding station in Morocco, and in the end he outfaced Voronoff and his many powerful supporters. Moreover testosterone had shortly before been isolated by (as Hamilton calls him) a Dr Funk. This was none other than Casimir Funk, the man who gave us the word vitamin and was said to have enraged the Mussolini regime when, learning that Italian prisoners taken in the Abyssinian War were being castrated by their captors, he attempted to negotiate a consignment of the resulting material. Injections of testosterone were found ineffective in the treatment of sexual decline. So began Voronoff's years of eclipse.

David Hamilton has penetrated the shell of Voronoff's formidable public persona, and come to like the man within, self-seeking *poseur* though he quite evidently was. *Tout comprendre*, as they say, *est tout pardonner*. The book is dedicated to Serge-Samuel Voronoff. □

Medical matters

Lewis Thomas

The Oxford Companion to Medicine, Vols I and II. Edited by John Walton, Paul B. Beeson and Ronald Bodley Scott. *Oxford University Press: 1986. Pp.1,524. £55, $95.*

I PICKED up the first of these two volumes at 11 o'clock one evening, and could not lay it down until 11:05. This sounds like the start of an uncordial review, but it means only to say quickly that this new encyclopaedia is not made for steady late-night reading. But for leafing through at random, in spare moments, with nothing particular in mind, *The Oxford Companion to Medicine* contains some unexpected pleasures. All in all, it is an earnest but good-natured piece of work, 1,500 or so pages of what seem rather randomly selected topics, some of them just a few lines of definition, others lengthy essays on one or another aspect of medicine, health, disease, medical practice, and quite a lot on the organization and economics of medicine.

Among the surprises, for me anyway, is a long essay on Doctors as Patients ("doctors have a healthy skepticism about the efficacy of the art they practice"), Doctors as Athletes, Doctors as Missionaries, Doctors in Other Walks of Life (the arts, the law, philosophy, the Church, crime).

Although the editors state in their preface that they hope for a readership made up of intelligent laymen as well as physicians, nurses and other health care professionals, including students, my guess is that the volumes will be most appealing to people who simply like browsing, whatever their background. If, as the editors hope, there is "a plastic surgeon wishing to learn more about the role and responsibilities of a psychiatrist", he will find plenty to read, eleven pages on Psychiatry and another ten on Psychology in Relation to Medicine. The psychiatrist, for his part, will find five pages on Plastic and Maxillofacial Surgery, directly following a short paragraph explaining Plaster of Paris. And any practitioner or layman wanting to know more about Death, Dying and the Hospice Movement, or about Government and Medicine in the UK (and also in the USA), or about Community Medicine, or Dentistry, or Cardiothoracic Surgery, or Medical Museums, or the Medical Services of the Royal Navy, or Women in Medicine, will find pages of essays on these and other broad topics. But, along the way, the casual reader will run into the Opening Snap ("associated with mitral valve opening at the beginning of diastole"), Suffocation ("the interruption of breathing by deprivation of air"), Weakness ("lack of strength, feebleness, ill health"), Neurotoxin ("any agent which is toxic to nervous tissue") and a lot of other items not needing even the one or two lines given them.

Whatever the intended readership, one thing *The Oxford Companion to Medicine* is not: it is not, despite the title, any kind of guide for do-it-yourself-at-home medicine, and the lay person who shells out £55 with this in mind will be disappointed. There is, to my own disappointment, not even much material to enlighten the layman on what to stay away from, in the light of those endless shelves of paperbacks in every airport lounge providing promises by immunity-stimulating diets, magical exercises, trace metals, vitamins, rejuvenating lotions, even books on how to think straight. To be sure, if you go looking you can find some of this, under Fringe Medicine, Cults and Quackery. In the absence of an index (which these two volumes could surely use) you have to be lucky and browsing through the F's to find it, and even so this section deals mostly with the health frauds of the nineteenth century and not enough with the more outrageous follies of this one.

In short, this is a curious, rather unpredictable, almost quirky encyclopaedia. Some will find it useful in spots, interesting for some of the essays. I'm glad to possess it, but I'm afraid that long before my pages became thumbworn my thumbs would be pageworn. □

Lewis Thomas is Professor Emeritus at the Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, New York 10021, USA, and University Professor at the State University of New York, Stony Brook.

Evolution in the twentieth century

Joe Felsenstein

Sewall Wright and Evolutionary Biology. By William B. Provine. *University of Chicago Press: 1986. Pp. 545. $30, £25.50.*
Evolution: Selected Papers by Sewall Wright. Edited and introduced by William B. Provine. *University of Chicago Press: 1986. Pp. 649. Hbk $70, £59.50; pbk $25, £21.25.*

EVOLUTIONARY theory in the 1960s and 1970s was dominated by optimization, by the search for the quantity evolution would maximize. The mean fitness of a population was not precisely what natural selection would maximize in a Mendelian genetic system, so perhaps if we did enough theory we could find out what was. The picture hanging on our wall was of R.A. Fisher, who had emphasized the importance of natural selection in large populations. The contributions of Sewall Wright were acknowledged by all, but were considered to be of secondary importance.

Theoretical population genetics then saw itself as a branch of applied mathematics, and in need of more mathematical rigour. The only data to which we paid attention were gene frequencies of electrophoretic polymorphisms. The kinds of data which morphologists, palaeontologists and most systematists collected were ignored.

By the end of the 1970s many of these evolutionists working above the population level saw the neo-darwinian synthesis as irrelevant to their needs. Punctuated equilibrium and even neo-lamarckian alternatives gained adherents. The resulting controversies over punctuated patterns of evolution and species selection mechanisms have revived interest in complex fitness surfaces and small populations. The evolutionary views of George Gaylord Simpson and Ernst Mayr, both influenced by Wright, have been important in these debates. All of which has led to a remarkable resurgence of the reputation of Sewall Wright.

It is unusual for the details of a theoretician's work to be so relevant 70 years after his views were formed. It is even more unusual for a major account of his work and its influence to appear in his own lifetime. Provine's thorough and throughly admirable examination of Wright's life and influence, which is accompanied by a very useful collection of Wright's papers on evolution, is the best we have for any recent figure in evolutionary biology.

Sewall Wright was born in 1889, and grew up in Galesburg, Illinois, one of a generation of talented and energetic intellectuals from the prairies of Illinois and Wisconsin. One is reminded of people such as the poet Carl Sandburg and the photographer Edward Steichen; in fact, Sandburg married Steichen's sister, and Wright's father Philip was Sandburg's most influential teacher and first publisher (Sewall set the type and ran the press). Provine gives careful attention to these early years, and to the intellectual atmosphere in which Wright trained; his chapters on Harvard's Bussey Institution and on evolutionary theory after Darwin are worth the price of admission by themselves. Here, I was startled to discover how closely the present controversies over the relative importance of species selection and individual selection were paralleled by controversies at the turn of the century.

Provine also goes into detail — more than seems readable — on the physiological genetics which was Wright's main concern until his retirement. As a student learning two fascinating stories, on mammalian coat colours and mathematical genetics, I did not appreciate how closely they were bound together. One is the story of explaining a seemingly arbitrary array of colours by the concentrations and properties of enzymes. Part of its fascination is evolutionary: the appearance of the same genetic variants in different mammalian species (Himalayan in rabbits, Chinchilla in mice and Siamese in cats, for example). The other extends the genetic system to the population level, making predictions from the necessary regularities of the system of inheritance.

Early days — Sewall Wright in 1922.

Only later did I come to realize that the same person, Sewall Wright, was central to both stories, and that coat-colour genetics was critical to the formation of his views on evolution. A list of Wright's PhD students (pp. 189–190) discloses few who concerned themselves with population genetics, but makes his influence on American mammalian genetics palpable. He wrote major reviews of physiological genetics, and influenced Beadle and Tatum's famous work on *Neurospora* which led to the one gene – one enzyme hypothesis. Although Provine deals chiefly with Wright's evolutionary theories, he recognizes the importance of the work on gene action in coat colour in informing Wright's view of the role of gene interaction in the inheritance of quantitative characters.

After describing Wright's years at Harvard (1912–1915), the US Department of Agriculture (1915–1925) and the University of Chicago (1925–1955), Provine devotes most of the rest of the book to Wright's views on evolution and their influence. There are some surprises. For example, in the course of an extended consideration of Wright's "shifting balance" theory of evolution Provine argues that Wright changed his views substantially in the 1940s. Wright himself denies this, but Provine's evidence, largely drawn from Wright's papers, seems incontrovertible. Before 1940, he points out, systematists believed that differences between species were of little or no adaptive significance. Wright's theory, originally developed with animal breeds in mind, could be applied to natural populations by supposing that random differences arose between species by genetic drift, and that selection between species utilized these to produce a net adaptive response. Provine believes that evolutionary biologists during the 1920s and 1930s did not understand the role of between-group selection in Wright's theory, that they understood him to be saying that genetic drift was the primary agent of evolution.

After 1940, as systematists and population geneticists reinterpreted species differences as being largely adaptive, Wright modified his theory. He brought it closer to the original animal-breeding model by having the random differences arise between local populations rather than between species. Provine finds evidence that this unadvertised change of views was a source of much confusion, playing a role in the famous post-war disputes with Fisher and Ford.

The controversies with Fisher are given careful attention. Provine takes pains to point out the reasons why these two came to disagree so completely about the evolutionary forces operating in nature, despite their agreement on most of the mathematical details. As long as we lack a comprehensive picture of the patterns of gene interaction and population structure in a wide range of species, the views of Fisher and Wright will form opposite poles of microevolutionary theory. One pole emphasizes optimization by natural selection in large populations with additive effects of genes, the other interaction of genes and interaction of natural selection and genetic drift. ►

I was surprised, too, to find how much of Wright's time during the 1930s and 1940s was taken up analysing Theodosius Dobzhansky's data for his famous series of papers on the "Genetics of Natural Populations", and how dependent Dobzhansky was on Wright's suggestions and analyses. Provine's treatment is extensive and illuminating, and indicates the underlying objectives of many of Dobzhansky's papers. Indeed, Provine's book will be an excellent starting point for a study of Dobzhansky's papers; through it the new student in evolutionary biology may be able to appreciate that genetic variation was once much more difficult to find and measure than it is today.

As the title indicates, *Sewall Wright and Evolutionary Biology* concentrates upon Wright's views and influence on evolutionary biology, and is not a general account of Wright's life or science. Although Wright's work on mathematical genetics is mentioned, Provine devotes little space to it. A symptom of this is the omission of the five essential "systems of mating" papers of 1921 from the collection of papers. On the mathematical theory Provine makes a few false steps. After pointing out that there are three logically distinct versions of Wright's concept of a fitness surface, he argues forcefully that these are logically unconnected, that Wright has spread confusion by using two of the notions interchangeably, and that population geneticists mistakenly assume that the two notions are related. Provine is mistaken in this: you really *can* derive the gene frequency adaptive surface from the genotype adaptive surface by taking a weighted average.

Wright's personal life is treated, but only rather briefly and circumspectly. Many population geneticists have Sewall Wright anecdotes, most of which do not appear in Provine's book. I did not find my favourites: "Sewall Wright And The Coffee Cup", "Sewall Wright Penniless In Berkeley" and "Sewall Wright Lectured On Genetic Drift". To his credit Provine does mention the most famous of all, noting both Wright's denial and the numerous people who claim to have seen him absent-mindedly erase a blackboard with one of his guinea pigs.

Twenty years ago I happened to be the person who first suggested to Provine that he should interview Sewall Wright (Provine was surprised to hear that Wright was still alive). Now I'm glad I did, because the result is a remarkable book. As we face the interesting possibility that Wright will be the keynote speaker at his own centennial celebration, his influence on evolutionary biology is greater than it has ever been. We will be listening to that speech with more than just polite attention. □

Redouté requiem

Sandra Raphael

Wonders of Creation: Natural History Drawings in the British Library. By Ray Desmond. *The British Library: 1986. Pp.240. £25.*

A Redouté Treasury: 468 Watercolours from Les Liliacées of Pierre-Joseph Redouté. Text by Peter and Frances Mallary. *Dent, London/Vendome Press, New York: 1986. Pp.228. £40, $50.*

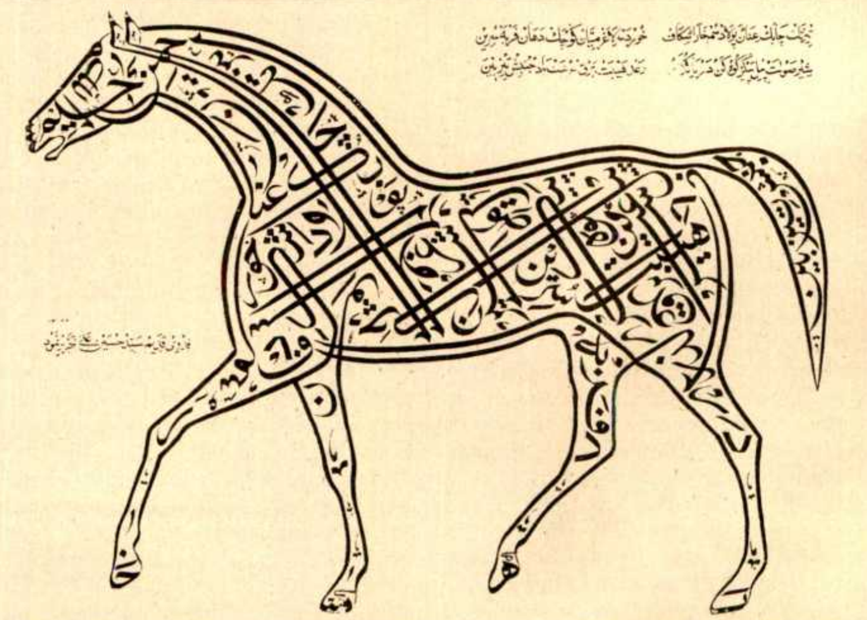
Wonders of Creation contains a selection of illustrations of plants and animals from manuscripts and drawings in various departments of the British Library, with a few pictures from printed books added to demonstrate the changes in style and taste described in the text. The choice seems to have been made almost at random in an attempt to include something for everyone, from flowers and trees, to birds, fishes, snakes, terrapins, rhinoceroses, koala bears, beetles, spiders and Stamford Raffles's "hairy-nosed otter". The sources range from mediaeval manuscripts to nineteenth-century drawings. The coloured plates (nearly 50 of them) are at the back of the book, each with its own short description, while the black-and-white illustrations are used to break up a short text that gives a rather pedestrian survey of the development of illustration as an aid to the descriptive work of naturalists.

The British Library collections in this field are quite rich, but it seems perverse to isolate them from the complementary and even richer hoards in the Natural History Museum in Kensington and the Print Room of the British Museum, still under the same roof as the British Library. In spite of the book's restrictions, the beauty of many of the pictures, oriental or European, will surely please browsers.

On 20 November 1985 Sotheby's in New York sold for $5.5 million the Empress Josephine's copy of Pierre-Joseph Redouté's *Les Liliacées* (1802–1816), 16 volumes containing 468 original watercolours on vellum as well as the printed text. *A Redouté Treasury* is a revised version of the sale catalogue, with colour photographs of the drawings of plants of the lily family and related groups rearranged and supplemented by a longer introductory essay and botanical notes.

Although *Les Liliacées* was sold as a single lot, it has since been dismantled by its buyer, a "breaker" who specializes in taking apart colour-plate books and selling their illustrations piecemeal. This process is sad enough when its subject is a relatively ordinary book, but when it is applied to one that is unique it becomes a bibliographical scandal. Redouté's drawings for *Les Liliacées*, possibly his masterpiece, were bought by his patron Josephine, whose garden at Malmaison provided many models for the artist. The drawings were inherited by Josephine's son, and all but 19 of them were bought by an American dealer, Edward Weyhe, in Zurich in 1935. Now they have been sold again. The drawings have been taken out of their fine bindings, so that this example of a great artist's greatest work has now been scattered and will never again be seen whole. *A Redouté Treasury* may be seen as a requiem for a French national treasure, now ruined. □

Sandra Raphael, 18 Argyle Street, Oxford OX4 1SS, UK, was the natural history editor of the new Supplement to the Oxford English Dictionary, *the last volume of which was published earlier this year.*



Piety in art — an example of Tughra *calligraphy. The opening verses of the* Koran *start at the horse's mouth, while the rest of the text praises the physical qualities of the animal.*

From Wonders of Creation

NEW BOOKS FROM CHAPMAN AND HALL

Tenth Edition

The Biochemistry of the Nucleic Acids

R. L. P. ADAMS, J. T. KNOWLER and D. P. LEADER

The tenth edition of this book has been almost totally rewritten and reorganised to allow a more logical presentation of material — it now provides a clear, wide-ranging and up-to-date account of gene structure and expression. This subject is a core part of all undergraduate courses in biochemistry and molecular biology, and this book is now established as the leading advanced text.

October 1986 544pp
Hb 0 412 27270 9 £35.00 Pb 0 412 27280 6 £16.95

Techniques for the Analysis of Membrane Proteins

Edited by **C. I. RAGAN** and **R. J. CHERRY**

Each chapter of this multi-author volume is derived from first hand experience and describes one approach unique to membrance protein research. Such a broad overview, coupled with specific examples and a guide to the important literature, provides valuable information to researchers wishing to introduce new approaches to their work.

October 1986 456pp Hb 0 412 24970 7 £48.50

The Lipid Handbook

F. D. GUNSTONE, J. L. HARWOOD and F. B. PADLEY

This major reference compendium covers the occurrence, isolation, chemical identification, and technological applications of this large and vital class of natural products.

August 1986 900pp Hb 0 412 24480 2 £95.00

A Topical Dictionary of Statistics

G. L. TIETJEN

A dictionary of statistical terminology in which the contents are arranged by topic rather than alphabetically.

November 1986 200pp Hb 0 412 01201 4 £17.50

Second Edition

Atlas of Stereochemistry – The Supplement

absolute configurations of organic molecules

J. BUCKINGHAM and **R. A. HILL**

This is a supplement to the two-volume Second Edition of the 'Atlas' by Klyne and Buckingham which was published in 1978, and which is the standard reference work on absolute configurations. It extends the literature coverage of the main volumes by six and a half years.

November 1986 c. 336pp Hb 0 412 26000 X £45.00

Third Edition

An Introduction to Radiation Protection

by **ALAN MARTIN** and **SAMUEL A. HARBISON**

Thoroughly revised and up-dated to take account of changes in legislations and standards, this book continues to serve as an introductory text for a wide range of readers involved with radiation in connection with nuclear power, nuclear medicine or for those in research, teaching and industry.

August 1986 264pp

Electrophoresis '86

Proceedings of the Fifth Meeting of the International Electrophoresis Society, London 1986
edited by M. J. Dunn

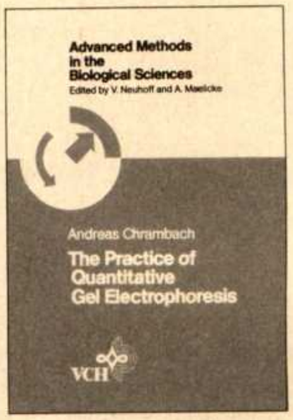
1986. XVIII, 765 pages with 231 figures and 37 tables. Softcover. DM 180.00/US $ 104.20. ISBN 3-527-26566-X

This collection of 72 papers and 72 poster abstracts reflects the latest trends and developments in electrophoretic techniques and their applications. The diversity of the seven major topics covered shows the broad scope as well as the flexibility of these techniques: cell and free flow electrophoresis, isotachophoresis, electrophoresis of nucleic acids, analytical electrophoresis of proteins and other compounds, isoelectric focusing, 2-D PAGE and preparative electrophoresis. Articles on the analytical electrophoresis of proteins and on two-dimensional electrophoresis account for more than half of the contributions, which indicates the focus of today's applications and research.

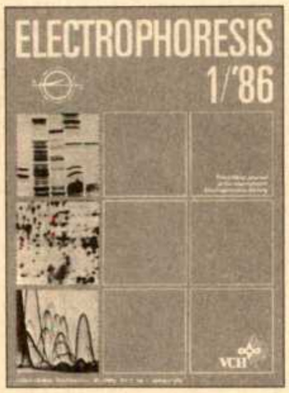
The Practice of Quantitative Gel Electrophoresis

by A. Chrambach

Series: Advanced Methods in the Biological Sciences, Volume 1
edited by V. Neuhoff and A. Maelicke. ISSN 0178-9244
1985. XV, 265 pages with 72 figures and 5 tables. Hardcover.
DM 110.00/US $ 43.60. ISBN 3-527-26039-0



Editorial advisory board of the series:
G. Dowdle, M. J. Dunn, R. Endean, G. Engel, P. Fromageot, M. Osborn, M. Rajewsky, E. Reich, D. Söll, S. Strickland, A. Ullrich, U. Zimmermann.
This book presents gel electrophoretic procedures which are generally applicable to the identification and isolation of charged molecules. All methods have proved reliable and are used in daily laboratory work. Also the equipment required for gel electrophoresis is described in detail. For items that are not commercially available, the reader gets all the information needed to do the construction himself. Theoretical aspects are covered to the extent that they are indispensible for the application of a method. A comprehensive index completes the book and makes it a reliable reference work.



Electrophoresis

The Official Journal of the International Electrophoresis Society

1987. Volume 8. Published monthly. Annual subscription rate including index DM 410.00 plus postage and handling charges. Special subscription rates for personal members of the International Electrophoresis Society, British Electrophoresis Society, French Electrophoresis Society, German Electrophoresis Society, and the Japanese Society of Electrophoresis are available on request. ISSN 0173-0835

Electrophoresis is a journal that stimulates communication between scientists in many fields such as biochemistry, clinical chemistry, genetics, immunology, microbiology and food science by presenting innovative applications of electrophoretic methods.

Electrophoresis publishes articles in English. The highest editorial standards are obtained through the cooperation of an Editorial Board, composed of world-renowned specialists.

Electrophoresis publishes original papers, short communications and review articles. Research reports are written with particular emphasis on advanced methods of electrophoresis. Topics include new and improved analytical and preparative methods and theoretical aspects. Other features include book reviews, important conference dates and miscellaneous information.

The scorbutic story

John Rivers

The History of Scurvy and Vitamin C. By Kenneth J. Carpenter. *Cambridge University Press: 1986. Pp.288. £27.50, $39.50.*

John Le Carré might have told this story better, but I doubt that he could have produced a better book. Like Kenneth Carpenter, Le Carré could have told the tortuous tale of 400 years of medical misunderstanding of scurvy, leading along false trails, down blind alleys and round and round in circles. And Le Carré would if anything have made the reader more aware that, because scurvy was a disease that particularly afflicted armies and especially navies, we are dealing not only with medicine but with grand strategy. The real difference in treatment would come in the last chapter where, the history of scurvy having become the story of the discovery of vitamin C, the author presents a scientific retrospect in which centuries of confusion are put beneath the spotlight of modern knowledge. If Le Carré had unleashed Smiley on these problems, the dénouement would have been far more slick.

Professor Carpenter, however, has been too honest and thorough in his analysis to pretend that all the questions are now resolved. Some, of course, are: the mystery of why the Esquimaux didn't get scurvy, despite eating no vegetables and fruit, is explained by the ascorbic acid content of fresh raw meat. But other problems remain perplexing even today. Why, for example, were so many cases of shipboard scurvy apparently cured by the once-favoured mixture of vinegar and potassium nitrate? The mixture contains no vitamin C; so was it lies, self deception, a placebo effect on an unprecedented scale or something we don't yet understand. The problem is left hanging.

Some certainties fall apart beneath Carpenter's critical analysis. James Lind, for example, doesn't seem anywhere near so epoch-making when Carpenter has finished with him. On the bicentennial of the publication of *A Treatise on Scurvy*, Lind was beatified by scientists as the inventor of the clinical trial and the first truly modern nutritionist. But the Lind to whom Professor Carpenter draws our attention ends up more human, someone who despite his studies on lemon juice as an antiscorbutic believed that cold and damp air actually caused scurvy. By the end of his life, it seems, Lind was a deeply pessimistic man, doubting his own observations which he was unable to replicate in studies at Haslar hospital, where even the controls mysteriously recovered, and concluding in the third edition of his *Treatise* that "enlarged experience must ever evince the fallacy of all positive assertions in the healing art".

Captain James Cook, too, is seen in a more perceptive light. Cook's circumnavigation of the world was free from scurvy not simply because he used Lind's prescribed lemon juice. He took almost every antiscorbutic that anyone recommended, with the result that the trip provided no test of Lind's hypothesis. Indeed, says Carpenter, Cook may have delayed the general introduction of lemon juice as a prophylactic because every theorist drew sustenance for their pet idea from his provisioning strategy; the award of the Royal Society's Copley medal to Cook, for his success in avoiding scurvy, seems to have been supported by Sir John Pringle, the President of the Royal Society, because he regarded Cook's triumph as evidence in favour of his favourite hypothesis that malted grain was the preventative of choice.

Such re-evaluations are the result of careful research on Professor Carpenter's part, not idle iconoclasticism. Indeed, in springing to the defence of the Admiralty, Carpenter attacks the iconoclasticism of others. It is often held that the continuance of scurvy in the British navies during the nineteenth century was the result of the Admiralty's penny-pinching decision to abandon lemon juice in favour of lime juice from the West Indian colonies which, though cheaper, had no vitamin C activity. The truth is not so simple. Not only are limes a good source of vitamin C, but the words lemon and lime were used interchangeably and it is not always possible to be sure what was being done. Carpenter suggests that the ineffectiveness of lime juice may have been due to catalysis of the oxidation of the ascorbic acid by copper in the stills and vessels used to concentrate the juice, compounded by overlong storage. The Admiralty was doing its best; it was the scientists who were wrong.

This is an extremely detailed book, and at times I wondered whether Carpenter should not have begun with the modern knowledge of vitamin C to aid the reader in interpreting the sheer mass of erroneous evidence and theory that runs down the centuries: a sort of answers first, questions afterwards strategy. But the lack of certainty in the final clarification shows that we don't yet have all the answers, and some questions must just remain. That alone makes the book worthwhile, as well as delightful to read, and a volume that will inform and entertain both historians and scientists — and, indeed, anyone who likes a good mystery story, even if it isn't written by Le Carré. ☐

Inside development

John C. Gerhart

Molecular Biology of Development. Volume L, Cold Spring Harbor Symposia on Quantitative Biology. *Cold Spring Harbor Laboratory: 1986. Pp. 920. Hbk $140; pbk $70.*

AT THE very least, this is yet another outstanding volume to arise from the annual Cold Spring Harbor Symposium, now in its fiftieth year. The papers — over 100 of them — come from leading molecular biological and genetic laboratories; they cover the subjects of nucleo-cytoplasmic interactions, cell lineage, segmentation, homoeotic mutants, homoeoboxes, tissue-specific gene expression, sex determination, cellular differentiation and developmental neurobiology. There is probably no book on the molecular biology of development to match this one, not only in the comprehensiveness of the coverage, but also in the care of preparation of individual papers, an indication of the authors' high regard for the occasion of a Cold Spring Harbor meeting. Most of the contributions are no-nonsense research accounts which assume a technical background and discuss only the immediate implications of results. Broader orientation is available by way of a general introduction by John Gurdon, and a summary of symposium highlights by Gerald Rubin. In this rapidly changing field, the papers cannot be expected to remain current for very long; the volume should be studied forthwith.

What is the molecular biology of development, as revealed in this volume? Joe Sambrook writes in his foreword:

> Developmental biologists are an audacious breed. Their ambition is to provide an intellectually satisfying account of the forces that guide development of multicellular organisms around the circle from fertilized egg to adult to gamete. These processes, however, lie close to the border beyond which genetics may not be feasible nor necessarily useful; furthermore, meaningful biochemical studies pose extraordinary challenges because of the small amounts of material that are available and the general rapidity of events in the early embryo. In the face of these difficulties it is not surprising that for many years developmental biology was essentially a branch of anatomy, in that it was exclusively descriptive in nature. Accurate and elegant though these descriptions were, they led to an understanding of developmental processes less frequently than to an amazement at their beauty.
>
> In recent years, however, developmental biology has undergone a dramatic change and has matured from a descriptive to an analytical science. There is no doubt in my mind that this change stems almost entirely from two technical advances — the ability to use molecular cloning to isolate and characterize mutant and wild-type versions of genes that control or are expressed at specific developmental stages and second, the ability to generate transgenic organisms in which the expression of the introduced gene(s) is correct both spatially and temporally. In consequence, the developmental biologist has not only the capacity to describe but also now to analyze and influence the events that guide a fertilized egg to its destiny.

In the book, it seemed to me that the excellent description by I. Herskowitz of the mating-type locus in yeast approaches most closely the kind of "intellectually satisfying account" now aspired to by molecular biologists studying development (for example those working on sex determination, segmentation and homoeosis in *Drosophila*). Herskowitz indicates (1) how certain master regulatory genes encode DNA-binding proteins which directly control the expression of batteries of cell-type-specific genes, and (2) how these master regulatory genes are themselves regulated by products of the *HO* gene, which is activated within mother cells by the products of yet other genes of the *SWI* family. Finally he suggests (p. 572),

> returning to the egg, we can imagine that regulatory proteins such as the *SWI* products become asymmetrically distributed to sister blastomeres. They activate expression of genes analogous to *HO* that govern activity of a regulatory locus (analogous to *MAT*) that ultimately triggers cell specialization.

Several contributors trace similar thoughts to those of T. H. Morgan (*Embryology and Genetics*, 1934, p. 10):

> The initial differences in the protoplasmic regions [of the egg] may be supposed to affect the activity of genes. The genes will then in turn affect the protoplasm, which will start a new series of reciprocal interactions. In this way we can picture to ourselves the gradual elaboration and differentiation of the various regions of the embryo.

Thus, in scanning this volume, I sensed fair agreement among participants that new information on genetic regulatory hierarchies is compatible with the long-appreciated phenomenon of cytoplasmic localization (an *intra*cellular, lineage-specific phenomenon) and can be grafted on to it to give an intellectually satisfying account now identifiable as the molecular biology of development.

Is there more? As John Gurdon points out, vertebrate development is thought to depend primarily on arborizing cascades of ever more local inductive cell–cell interactions. The highly regulative nature of vertebrate embryos indicates the ongoing ability of individual cells to adapt their paths of development to *inter*cellular conditions. Imaginal disc regeneration and transdetermination also reveal the importance of continuous cell–cell interactions in invertebrate (*Drosophila*) development. These complex, multiple interactions, while mentioned in the volume, have an uncertain relationship to the genetic control of cell differentiation and to lineage-restricted cytoplasmic factors. If embryonic cells produce and respond to a great variety of *inter*cellular contexts, and if a cell's particular path of development (including its changing profile of gene expression) is highly adaptable to that context, then regulatory genes would themselves be subject to extensive regulation, and would seem to be rather less masterful in their control of development, even though they would function to control other genes and play an important inertial rôle in connecting the cell's past to its present. In organisms making use of cell–cell interactions to select developmental paths, gene-regulating genes might be elements of much larger intercellular regulatory circuits having many components, many inputs, multiple states and adaptability. (It's one thing to say that a gene controls other genes; it's another to say that a gene controls development.)

If this is the prospect, then with the help and stimulus of the exciting new analytical techniques, and with genetic dissection, we can look forward to a long period of amazement at the beauty of our enlarging description of development, as the molecular biology of development turns outwards from the nucleus. ☐

NUCLEAR POWER AND ITS ENVIRONMENTAL EFFECTS

For the Layman, Nuclear Technician, Manager

Places the effects of possible nuclear radiation in perspective. Meets the need for a better understanding of radiation and its consequences especially after the TMI accident.

All vital aspects of nuclear power generation are considered, from fundamental principles to plant licensing, from uranium mining to disposal of waste. The safe operation of nuclear power plants, to prevent the escape of dangerous amounts of materials in case of an accident, is fully covered.

Feeling for nature

Robert M. May

Gilbert White: A Biography of the Author of The Natural History of Selborne. By Richard Mabey. *Century Hutchinson, London:1986. Pp.239. £14.95.*

ONLY three books in the English language have gone through more editions than Gilbert White's *The Natural History of Selborne*. This claim leaps out from the blurb on the back of the 1977 Penguin edition, and has left me wondering what ranks third behind the Bible and Shakespeare; probably *Pilgrim's Progress*. The separate editions of *Selborne*, over 200 of them, have appeared at a steady rate since the book was first published in 1789 (note the impending bicentenary), forming an interesting record of changing tastes in book design and changing visions of the countryside as revealed in the illustrations.

On first acquaintance, *Selborne* is a surprising book to have evoked such unwavering affection. As Mabey observes, it is

> the kind of book presented on prize-giving days, ... a work, in all senses, of the old school. Even when I eventually came to read it, I cannot say my opinion changed dramatically. I could not cope at first with its rambling disorder, its sudden plunges into thickets of taxonomic Latin, and, for a while, I failed to notice the feeling behind the often dispassionate prose.

Selborne is organized as a collection of letters, similar to many other works about local natural history by enthusiastic parsons. It endures while these other books ornament the libraries in stately homes because beneath its unassuming surface is a fully contemporary appreciation — quite new in its own time — of plants and animals as more than curiosities, but as parts of a community, interacting among themselves, with their environment and with humans. White raises general questions (such as how populations are regulated), but always against a background of keenly observed detail (the breeding success of swifts, the singing of crickets, or the way fly-catchers keep their fledglings cool in summer by fanning their wings above the nest).

Richard Mabey has produced the first biography of Gilbert White for over 80 years. The difficulty is that not a lot is known about White, except that he lived an uneventful bachelor life in the parish and rarely left it (as Richard Boston observed, reviewing the book in *The Guardian*, how else could White have described the South Downs as "that chain of majestic mountains"). Mabey's book is more in the nature of an introduction to, and appreciation of, *Selborne*, than a biography in the strict sense. At such, it does a fine job of relating Gilbert White and his book to the village of Selborne as it was then and is now. Despite his observations, White never fully gave up the contemporary notion that swifts and swallows disappeared in winter because they hibernated; Mabey empathizes, suggesting that White simply could not imagine why anyone could want to leave Selborne.

Mabey explains that "it was seeing Selborne itself, the source of White's inspiration, that changed my view [quoted above] decisively, and helped me to understand what the book was truly about". The patterns of field and woodland around the village have changed little since White's time, and the village itself conducts its Gilbert White trade in a low-key way (the stained glass memorial window in the church, with White as Saint Francis among his birds, is alone worth a visit: see the cover illustration of *Nature*, 22 December 1983). Visit Selborne and read Mabey. Then read *The Natural History of Selborne*. ☐

In the groove

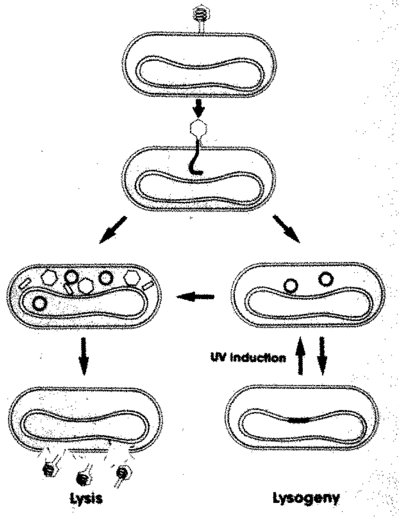
Sydney Brenner

A Genetic Switch: Gene Control and Phage λ. By Mark Ptashne. *Cell Press, Cambridge, Massachusetts/Blackwell Scientific: 1986. Pp.128. Pbk $16.95, £14.50.*

MAX Delbrück did not believe in lysogeny. He thought that the persistence of bacteriophages in some bacterial cultures was due to cryptic infection and he dismissed it as a fringe phenomenon. Everybody he influenced therefore worked on virulent bacteriophages, especially T4, and their work led to one branch of molecular genetics and to the discovery of the fine structure of the gene, the general nature of the genetic code and messenger RNA. Fortunately, Delbrück's influence was not totally pervasive and in Paris, where there was a long tradition of research on lysogenic bacteria, the work of Lwoff and of Jacob and Wollman on bacteriophage λ revealed that lysogeny is in fact due to a gene regulatory mechanism that allows the phage DNA to remain silent in the bacterial chromosome until activated by, for example, ultraviolet light. Their major step was the realization that the properties of the phage mutants on which they worked were isomorphous with those affecting the expression of β-galactosidase, and that in both cases gene regulation was achieved by the negative effect of repression.

Mark Ptashne isolated the λ repressor in 1967 and has spent nearly 20 years in pursuing its molecular structure and mode of action. This little book is an account of his research, focused especially on how the λ repressor and *Cro*, another regulatory protein, form a switch by their interaction with an operator, O_R. In one state, corresponding to stable prophage, the binding of λ repressor inhibits the rightward transcription from the promotor site P_R and stimulates its own production by transcription in the direction from another promotor, P_{RM}. When the repressor is removed by proteolysis induced by ultraviolet light, rightward transcription is turned on and *Cro* is produced. The binding of *Cro* to O_R prevents any further synthesis at P_{RM}, thus turning off repressor, irreversibly throwing the switch and sending the phage down the lytic pathway. Ptashne shows how these events are precisely conditioned by the mode of binding of repressor and *Cro* to the three-component sequence of the operator. The structure of these proteins is known and both recognize the major groove of DNA through a characteristic α-helix–bend–α-helix, a motif now known to be present in a large number of DNA-binding proteins.

This work is a paradigm for the mechanisms of regulation but Ptashne would like to go further and sees the λ switch as the model for switching between develop-



Lysis or lysogeny — the alternative modes of growth of phage λ which are controlled by a switch mechanism operated by λ repressor and Cro *regulatory protein. Once it has entered the host bacterium (top), the phage DNA can either replicate autonomously and then lyse the host; or it can insert itself into the host chromosome and be propagated along with it until the lysogeny decision is reversed by, for example, irradiation of the bacterium with ultraviolet light. (Reproduced, reduced in size, from* A Genetic Switch; *the original is in two-colour.)*

mental pathways in higher organisms. In a general sense this is true because, logically, the λ system appropriately combines positive and negative feedback in a simple way to implement a switch; but this is not necessarily the only way it can be done. Years ago Novick performed a most illuminating experiment. Normally the galactosidase of *Escherichia coli* is repressed, but it can be released from repression (induced) in the presence of lactose or an analogue thereof. Novick briefly exposed *E.coli* cultures to a high concentration of an inducer which was then diluted a thousandfold to provide a maintenance level. In a fraction of the cells, enough of the inducer got in to derepress the genes; the rest remained uninduced. The resulting mixed population maintained itself indefinitely as long as the low level of inducer was present, because induction entails the production of a permease that increases the uptake of the inducer so that even at low levels enough can enter the cells to maintain the induced state. Thus it could be said that *E.coli* had "differentiated" into two cell types with heritable states. This result depends on the properties of the permease: only cells with permease can take up inducer at the low maintenance level and only such cells can have permease induced; transient induction at high levels simply initiates the process in part of the population. Here the logical elements of positive and negative feedback are implemented in another way and it is arguably a better paradigm for some developmental processes than the λ switch.

The analogy between the λ switch and developmental processes should not be carried too far. In discussing the difference between "commitment" and "differentiation" of cells, Ptashne writes

> By analogy, a λ-lysogen is indistinguishable from an uninfected bacterium by casual inspection, but the former and not the latter is 'committed' to lyse and release phage when it encounters an inducing signal in the environment.

However, he quickly realizes that this is not a good analogy because the difference between the bacteria is a *genetic* one and he continues

> The lysogen, of course, has genes that are lacking in the non-lysogen, but it is not difficult to imagine analogous forms of commitment involving only differential gene expression. To take a simple example, the regulatory proteins of a cell might turn on a gene encoding a hormone receptor.

Do we hear a faint echo of the permease paradigm?

But this is quite a minor criticism of a clear exposition of a series of triumphant experiments and insights that have brought us close to the molecular heart of the matter of genetic regulation. ☐

Sydney Brenner is Head of the Medical Research Council Molecular Genetics Unit, Hills Road, Cambridge CB2 2QH, UK.

Eastern originality

Christopher Cullen

China: Land of Discovery and Invention. By Robert K. G. Temple. *Patrick Stephens, Wellingborough, UK: 1986. Pp.248. £12.95.**

READERS of this journal will need no more than a brief reminder of the importance of the work of Joseph Needham. With the help of a large group of collaborators, over the past 40 years he has been engaged in a great project of research and publication on the history of science, technology and medicine in pre-modern China. The results are appearing in the pages of *Science and Civilisation in China*, the seven volumes of which are being published by Cambridge University Press as some 30 separate tomes (about half of them have appeared to date). This work is widely regarded as the most influential British contribution to historical scholarship in the present century, and it has certainly completely changed the perspective of many well-informed Westerners on the origin of important aspects of modern science.

As the weight of his research has accumulated, Needham has had to move far from his original aim of writing a short book for the general reader. Robert Temple's book, which is compiled almost entirely on the basis of material already published or awaiting publication in Needham's volumes, is intended to meet this need. Temple has divided his account into 11 broad subject areas, such as "Agriculture, Medicine and Health", "Magnetism" and "Warfare". Under these he has grouped a hundred short, illustrated essays on particular topics. Temple is clearly no mere hack compiler of coffee-table books: his writing is clear and vigorous, and he succeeds in communicating his obvious enthusiasm for the subject. It is hard to imagine anyone with a general interest in the history of science failing to find a great deal in this book to intrigue and delight.

There are some flaws. Temple makes no systematic attempt at writing history; the book is a series of vignettes on "the wonders of Chinese science", and as such does not convey any sense of the social and philosophical background from which Chinese science, technology and medicine arose and against which they functioned. The choice of topics and the balance between them sometimes seems odd: the section on engineering devotes more space to the novelties known as "spouting bowls" than to cast iron. Some of the statements are out of date or just plain wrong, and the one-page list of "further reading" is so incomplete that it does not even mention Colin Ronan's readable and reasonably priced abridgement of Needham's work, also published by Cambridge University Press. On the whole, however, Temple deserves the gratitude of his readers for having provided a ready means of access to a fascinating subject. ☐

Christopher Cullen, 86 Mount View Road, London N4 4JX, UK, is a former Research Fellow of Clare Hall, Cambridge, and has published mainly in the field of ancient Chinese astronomy and mathematics.

---

*To be published in the United States in January by Simon & Schuster, under the title *The Genius of China: 3000 Years of Science, Discovery, and Invention*. Price will be $19.95.

From *China: Land of Discovery and Invention*

Sowing sophistication — spring wheat being sown by seed drill in northern China. Seed drills, which are much less wasteful than broadcasting seed by hand, were available in China from the second century BC. *It was almost 2,000 years later that they came into use in Europe.*

Major new titles from Gordon & Breach and Harwood

New Perspectives in Nuclear Medicine

Proceedings of the IX Congress of the Latin American Association of Societies of Nuclear Medicine and Biology (ALASBIMN), Montevideo, Uruguay, December 9-13, 1984

Edited by Peter H. Cox and E. Touya
Volume 2 in the Monographs in the Nuclear Medicine series

A valuable reference work, reporting on the discovery and applications of new nuclear methods in diagnosis and therapy that have been made possible by recent technological advances in the field. Part 1 contains clinical *in vivo* studies; part 2 reviews instrumentation, laboratory investigations and *in vitro* studies.

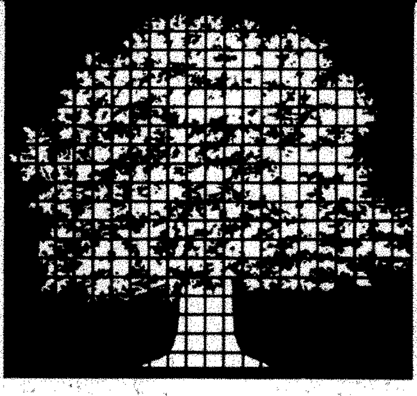
Tentative publication date:
January 1987 approx. 822 pp.
*2 volume set, hardcover 2-88124-131-X: $160.00; SAS member price: $80.00**
A Gordon & Breach set

New Approaches in Cardiac Mechanics

Edited by Kazuo Kitamora, Hiroshi Abe, and Kiichi Sagawa

This volume contains the results of collaborative research by cardiologists, physicists and engineers into cardiac mechanics. Emphasising the research and development of relevant methodologies, the articles review new approaches to cardiac function, from the mode of muscle contraction and its control to clinical assessment.

May 1986 330 + ix pp.
Hardcover 2-88124-126-3: $80.00
A Gordon & Breach book published jointly with Japan Scientific Societies Press.



Higher Integrative Systems of the Brain

by A.S. Batuyev

For physiologists, psychologists and philosophers, this book reviews the latest experimental data and ideas, and summarises current knowledge on the physiology of the brain's higher integrative systems and their role in shaping complex behavioral patterns in man and other animals.

Tentative publication date:
May 1987 approx. 286 pp.
Hardcover 2-88124-143-3, tentative price: $82.00
A Gordon & Breach book

Polymer Yearbook 3

Edited by Richard A. Pethrick

". . . the comprehensive academic library will want to have the series for its annual coverage of polymer science, not otherwise available to an interested reader. The layout, printing, accuracy, coverage and overall quality are excellent." – *Choice*

August 1986 337 + xiv pp.
Hardcover 3-7186-0342-X: $80.00
Softcover 3-7186-0341-1: $30.00
A Harwood book

Essays on DNA in Clinical Medicine

Edited by T.J. Wilkin

Discussing molecular biology techniques and their applications in areas from hormone bioassays to the diagnosis of genetic disease, and the ethical issues that arise from the use of bioengineering, this book offers the health practitioner, hospital clinician and medical student a solid understanding of some of the most exciting developments in modern medicine.

Tentative publication date:
March 1987 approx. 180 pp.
Hardcover 3-7186-0360-8, tentative price: $30.00; Softcover 3-7186-0361-6, tentative price: $18.00
A Harwood book

Synthetic Membranes

Edited by Maynard B. Chenoweth
Volume 5 in the MMI Press Symposium series

Covering the chemical, physical and commercial aspects of synthetic membranes, this book discusses the state of the art in membrane technology, its applications to medicine and areas such as food processing and water purification.

August 1986 288 + vii pp.
Hardcover 3-7186-0327-6: $80.00
*SAS member price $30.00**
A Harwood book

* **The Science and Arts Society (SAS)** is a bookclub designed to allow individuals to purchase high-level reference books with a saving of around 40% on all prices. Microbes in Extreme Environments

Edited by **R.A. Herbert and G.A. Codd**
September 1986, $35.00/£19.50(UK only), ISBN: 0.12.341641.X Pbk.
September 1986, $74.00/£41.00(UK only), ISBN: 0.12.341460.1 Hbk.

Contents: Preface. The Ecology and Physiology of Psychrophilic Microorganisms, *R.A. Herbert.* The Alkaline Saline Environment, *W.D. Grant and B.J. Tindall.* Halotolerant and Halophilic Microbes, *R.H. Reed.* Fungal Responses Towards Heavy Metals, *G.M. Gadd.* Strategies of Phototrophic Bacteria in Sulphide-Containing Environments, *H. van Gemerden and R. de Wit.* Damaging Effects of Light on Microorganisms, *G.C. Whitelam and G.A. Codd.* Pressure as an Extreme Environment, *R.Y. Morita.* Bacteria Adaptations for Growth in Low Nutrient Environments, *R.J. Sharp and M.J. Munster.* Genetic Applications of Alkalophilic Microorganisms, *K. Horikoshi.* Index.

The Rat Brain in Stereotaxic Conditions

Second Edition

George Paxinos and Charles Watson
November 1986, 264pp., $53.50/£44.50(UK only),
ISBN: 0.12.547621.3

The first edition of this stereotaxic atlas has been acclaimed as outstanding for studies on the brain of the laboratory rat. It represents a modern synthesis of data on the topography of the rat's brain and provides an accurate guide to identification and stereotaxic localization of structures for both researchers and students in the neurosciences.

Physiological Ecology of Forest Production

J.J. Landsberg
August 1986, 206pp., $45.00/£25.00(UK only), ISBN: 0.12.435965.5

Recent research has produced much new information on the physiology of forest trees growing together in a stand, and on the various effects of environmental factors on them. This book provides the first summary of this subject, dealing with every aspect from micrometerology to photosynthesis, carbon utilization and water relations.

Contents: Preface. Symbols and Definitions. Introduction. Process Rates and Weather. Stand Structure and Microclimate. The Carbon Balance of Leaves. The Carbon Balance of Trees. Nutrient Dynamics and Tree Growth. Water Relations. Synthesis.

Monoclonal Antibodies: Principles and Practice

Second Edition

J.W. Goding
October 1986, c.302pp., $29.50/£17.50(UK only),
ISBN: 0.12.287021.2

The second edition of this well known and widely accepted publication is a selectively updated volume. The improvements include clarification of detail and the incorporation of the rapid advances which have been made in this field.

Contents: Preface. Preface to Second Edition. List of Abbreviations. Introduction. Theory of Monoclonal Antibodies. Production of Monoclonal Antibodies. Purification, Fragmentation and Isotopic Labelling of Monoclonal Antibodies. Analysis of Antigens Recognized by Monoclonal Antibodies. Affinity Chromatography Using Monoclonal Antibodies. Immunofluorescence. Generation of Conventional Antibodies. Glossary. Index.

CAD/CAM and MIS in Japan

Computer Applications in Japanese Industry

Edited by **Noboru Takagi, John Branch and Keiji Yajiama**
November 1986, 417pp., $79.00/£49.00 (Tentative),
ISBN: 0.12.682580.7

This is the first publication on the Ishikawa Prize lectures which reflect the efforts to modernise Japanese industrial management.

The chapters have been grouped into the following categories: (1) building and architecture, (2) services, (3) industrial management, (4) industrial production, (5) transport and construction. A historical description of the development of Japanese industry in terms of this classification, written by the economist Mr Akira Kakuta, is given in an appendix.

High Performance Liquid Chromotography

Advances and Perspectives *Volume 4*

Edited by **Csaba Horvath**
December 1986, 330pp., $70.00/£58.50(UK only),
ISBN: 0.12.312204.X

From Reviews of Volume 3:

"These contributions represent more than a survey; they are a milestone in the advancement of HPLC."

— **Analytical Chemistry**

Contents: Reversed-Phase Chromatography of Proteins and Nucleic Acids: Practical Considerations. Mixed-Interaction Chromatography. Liquid Chromatography/Electrochemistry. High-Performance Liquid Chromatography Separations of Large Molecules: A General Model.

Protein-Carbohydrate Interactions in Biological Systems

The Molecular Biology of Molecular Pathogenicity

Edited by **D.L. Lark, S. Normack, B.-E. Uhlin, and H. Wolf-Watz**

October 1986, 496pp., $76.50/£42.50(UK only), ISBN: 0.12.436665.1

Contents. Session I, Genetics of Bacterial Adhesins. Session II, Antigenic Variation of Bacterial Adhesins. Session III, Role of Pili and Adhesins in Pathogenicity. Session IV, Carbohydrate Receptors: Identification, Analysis and their Biological Role. Session V, Adhesins: Their Receptors and Interactions. Session VI, Bacterial Inversion. Session VII, Bacterial Surface Components and their Importance for Virulence. Session VIII, Bacterial Toxins and Receptors.

Perinatal Genetics Diagnosis and Treatment

Edited by **Ian H. Porter, Norma H. Hatcher, and Ann M. Willey**

September 1986, 328pp., $45.00/£37.50(UK only), ISBN: 0.12.562855.2

A summary of the current state of the art in perinatal genetics. It clarifies and rationalizes certain aspects of diagnosis, genetic counselling, and management of genetic disease, and serves as a useful guide for health professionals who provide care to pregnant women and their newborns.

The Mineral Nutrition of Higher Plants

Horst Marschner

October 1986, 612pp.,
$39.95/£22.50(UK only), ISBN: 0.12.473541.X Pbk.
$89.50/£49.95(UK only), ISBN: 0.12.473540.1 Hbk.

Contents: Part I: Nutritional Physiology. Introduction, Definition and Classification of Mineral Nutrients. Ion Uptake of Individual Cells and Roots; Short Distance Transport. Long Distance Transport in the Xylem and Phloem and its Regulation. Uptake of Mineral Elements by Leaves (Aerial Parts). Yield Physiology and Source-sink Relationships. Mineral Nutrition and Yield Response. Nitrogen Fixation. Functions of Mineral Nutrients — Macronutrients. Functions of Mineral Nutrients — Micronutrients. Beneficial Mineral Elements. Relationship Between Mineral Nutrition and Plant Diseases and Pests. Diagnosis of Deficiency and Toxicity of Mineral Nutrients. Part II: Soil-plant Relationship. Nutrient Availability in Soils. Root Growth and Development as Affected by External and Internal Factors. The Soil-root Interface (Rhizosphere) in Relation to Mineral Nutrition. Adaptation of Plants to Adverse Chemical Soil Conditions.

Gene Activity in Early Development

Third Edition

Eric H. Davidson

September 1986, 675pp., $49.50/£41.50(UK only), ISBN: 0.12.205161.0

This new third edition reflects the ten years of technological progress since the last edition. Providing a unique blend of classical and molecular knowledge, it discusses all major embryonic systems from both a comparative and mechanistic point of view. In deriving overall interpretations of developmental phenomena, it brings into play all the disparate forms of evidence, including genetic, molecular, and cytological.

Monoclonal Antibodies Against Bacteria

Volume III

Edited by **Alberto J.L. Macario and Everly Conway de Macario**

1986, 340pp., $52.50/£44.00(UK only), ISBN: 0.12.463003.0

Monoclonal antibodies are making a major impact on virtually every field in the health sciences as demonstrated by their increasing use for the diagnosis, prophylaxis, and treatment of diseases caused by bacteria and their toxins. This multidisciplinary treatise provides a comprehensive and up-to-date reference source on new developments of practical importance in microbiology and infectious diseases, focusing on advances made possible by monoclonal antibodies.

Military Radiobiology

Edited by **James J. Conklin and Richard I. Walker**

1986, 390pp., $34.95/£29.50(UK only), ISBN: 0.12.184050.6

All radiation biologists and biophysicians should find this an interesting and valuable reference on the effects of catastrophic ionizing radiation on the body. The book includes discussion of cellular radiation biology, physiological effects of radiation, combined injury, radioprotectants, and low-level effects.

Pattern Recognition by Humans and Machines

Edited by **Eileen C. Schwab and Howard C. Nusbaum**

Volume 1: Speech Perception, July 1986, 336pp.,
$29.95/£25.00(UK only), ISBN: 0.12.631403.9 Pbk.
$59.50/£49.00(UK only), ISBN: 0.12.631401.2 Hbk.

Volume 2: Visual Perception, July 1986, 264pp.,
$23.95/£20.00(UK only), ISBN: 0.12.631404.7 Pbk.
$46.50/£39.00(UK only), ISBN: 0.12.631402.0 Hbk.

These two volumes address fundamental problems in cognitive science, those of perceptual processing in humans and machines. They present a broad view of the field, with contributions by leading researchers in psychology, artificial intelligence, brain theory, speech and vision.

Environmental Radioactivity from Natural, Industrial and Military Sources

Third Edition

Merril Eisenbud

November 1986, 444pp., $55.00/£46.00(UK only), ISBN: 0.12.235153.3

Contents: Introduction. The Biological Basis of Radiation Protection. Radiation Protection Standards. Some General Considerations Concerning Environmental Radioactivity, Including the Use of Models. Transport Mechanisms in the Environment. Terrestrial and Aquatic Pathways. Natural Radioactivity Production and Reprocessing of Nuclear Fuels. Power Reactors. Various Other Sources of Exposure. Radioactive Waste Management. Fallout from Nuclear Explosions: I. Short-Term Effects. Fallout from Nuclear Explosions: II. Worldwide Effects. Accidents that Resulted in Contamination of the Environment. Radiation Exposure and Risk: Some Contemporary Social Aspects.

SCIENTIFIC AMERICAN

Autumn Reading from

New

Tilings and Patterns

Branko Grünbaum and G C Shephard

Visually attractive and intellectually rich, this unique, definitive book is indispensable to mathematicians, and fully accessible to any reader interested in this fascinating 'real-world' aspect of geometry.
November, 640 pages, 517 illus, board £54.95

Knotted Doughnuts and Other Mathematical Entertainments

Martin Gardner

This eleventh and latest collection of Martin Gardner's celebrated *Scientific American* columns, provides hours of enjoyment with an entirely new set of problems, paradoxes, teasers and tricks.
November, 288 pages, 207 illus, board £16.95, paper £10.95

Introduction to Comparative Cognition

Herbert L Roitblat

The first comprehensive introduction to thinking, information processing and memory in animals, with emphasis on the approaches, methods and goals of comparative cognition.
November, 384 pages, 60 illus, board £29.95, paper £17.95

Scientific American Library

Drugs and the Brain

Solomon H Snyder

A new title in the *Scientific American Library* dealing with the clinical effects of the major classes of psychoactive drugs, focusing on the use and abuse of a number of powerful and notorious drugs.
November, 256 pages, 148 illus, board £15.95

Forthcoming titles

Remote Sensing 2/e
Principles and Interpretation

Floyd F Sabins, Jr.

This acclaimed work has been thoroughly revised and updated to include explanations of the most modern remote sensing systems and the skills needed to interpret all forms of imaging technology.
December, 592 pages, 568 illus, board £47.95

Teaching Thinking Skills
Theory and Practice

Edited by Joan B Baron and Robert J Sternberg

A collection of essays by twelve eminent psychologists, educators, and philosophers that unite classical and modern theories of thought with the latest practical approaches to the learning and teaching of thinking skills.
January 1987, 304 pages, board £21.95 approx.
paper £12.95 approx.

Public Appearances, Private Realities
The Psychology of Self-Monitoring

Mark Snyder

This is the first thorough, integrated look at what the theories, research, and applications of self-monitoring tell us about our own social behavior and about the nature of the self in general.
January 1987, 320 pages, 12 illus, board £25.95 approx.
paper £13.95 approx.

Origins of Sex

Lynn Margulis and Dorion Sagan

A fascinating and detailed examination of the evolution — and occasional devolution — of sexuality in microorganisms and more complex forms of life. Key issues discussed include the origin of meiotic sex through cannibalism, the connections of sex and differentiation to cell symbiosis, and the loss of sex.
Illus. £30.00

The Shaping of America

A Geographical Perspective on 500 Years of History
Volume I: Atlantic America, 1492-1800
D. W. Meinig

This entirely fresh interpretation of American history by a renowned historical geographer is the first in a projected three-volume series. In this volume, Meinig focuses on colonial America, examining how an immense diversity of ethnic and religious groups — Europeans, Africans, American Indians — ultimately created a set of distinct regional societies.
81 *b & w illus.* £35.00

The First Resource

Wild Species in the North American Economy
Christine Prescott-Allen and Robert Prescott-Allen

Christine and Robert Prescott-Allen here provide the first systematic analysis of the economic importance of wildlife to North America in a book with important implications for economic and development policies.
Illus. £58.00

Migrations in Prehistory

Inferring Population Movement from Cultural Remains
Irving Rouse

In this book Irving Rouse evaluates research on prehistoric migrations, from the successfully formed and tested hypotheses explaining the origins of the Polynesians, Eskimos, Japanese, and Tainos, to the more fanciful postulations by authors such as Thor Heyerdahl and Barry Fell. Rouse's work demonstrates the effectiveness of collaboration and communication between branches of archaeology and anthropology.
30 *b & w illus.* £20.00

The Hawk's Nest Incident

America's Worst Industrial Disaster
Martin Cherniack, M.D.
Foreword by Phillip Landrigan, M.D. and Anthony Robbins, M.D.

This engrossing and disturbing book tells the story of the worst occupational health disaster in American history, which occurred fifty years ago when hundreds of men died and over a thousand fell ill from acute silicosis contracted during the building of Union Carbide's Hawk's Nest Tunnel in West Virginia.
Illus. £19.95

Encyclopedia of Physical Science and Technology

Robert A. Meyers, *Editor-in-Chief*

The **Encyclopedia of Physical Science and Technology** is the contemporary reference for today's high technology. It is a unique source, and the first to encompass all aspects of the physical sciences. A complete technical library, the **Encyclopedia** is:

.....DETAILED

• 15 volumes... including a separate index volume • Over 500 original articles each approximately 20 pages long • 6,000 illustrations - 2,000 tables • 11,000 double column pages • Extensive cross referencing.

.....COMPREHENSIVE

The **Encyclopedia** covers these major subjects:

• Aeronautics • Astronomy & Astrophysics • Atmospheric Sciences & Aeronomy • Chemistry • Communications • Computers & Controls • Earth Sciences & Oceanography • Electronics & Electrical Engineering • Materials Science & Engineering • Mathematics • Mechanical, Industrial, and Civil Engineering • Military Sciences • Navigation, Military Communications • Nuclear Technology • Ordnance • Physics • Power Systems, Non Nuclear & Non Propulsive • Propulsion & Fuels • Space Technology.

.....AUTHORITATIVE

All articles are written by world authorities in their fields... Nobel Prize winners and recipients of the National Medal of Science.

.....ORGANIZED

Articles are arranged alphabetically and include: table of contents, glossary of unusual terms, concise definition of subject, *in depth* presentations, extensive cross references, illustrations, tables and a bibliography.

The **Encyclopedia of Physical Science and Technology** is *the* required reference for today's scientist, engineer and student.

A Biologist's Guide to

Principles and Techniques of Practical Biochemistry

THIRD EDITION
Edited by **K. Wilson** and **K.H. Goulding**

'. . . continues to be an excellent, clearly written textbook.' *Biologist* on the last edition. This book concentrates on those up to date techniques commonly used in biochemistry, which all students of biology would be expected to encounter during their course of study. All chapters have been revised and two new chapters cover enzyme assay techniques and methods used in molecular biology.

Publication October 1986
416 pages line and half-tone illustrations

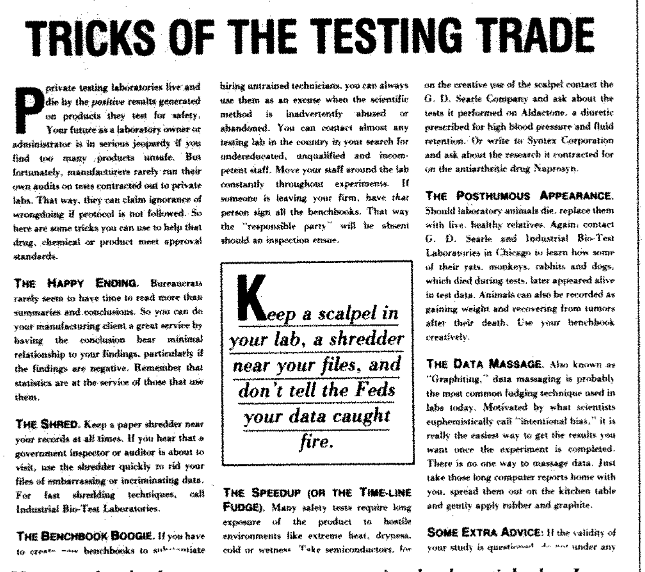
Deception beyond measure

C.R.B. Joyce

False Prophets: Fraud and Error in Science and Medicine. By Alexander Kohn. *Basil Blackwell: 1986. Pp.221. £14.95. To be published in the United States in January 1987, $24.95.*

As THIS book and its chief rival, William Broad and Nicholas Wade's *Betrayers of the Truth** both remind us, Charles Babbage distinguished three unorthodox ways of dealing with data. These he called, in increasing order of impropriety, trimming, cooking and forging. Are such behaviours more common today than they were in Babbage's time? In his very first sentence Alexander Kohn states that the exponential growth of science has been accompanied by the "appearance" of deviant scientists, as if a rectilinear growth would not have given rise to the problem. It is not clear whether he thinks that there has been an increase in the number of such individuals, as Broad and Wade imply; and, if so, whether this is absolute or proportional. In fact, there have been more attempts than Kohn realizes to answer the question, but it is not an easy one to tackle, requiring as it does methods learnt from the confessional, the KGB and Social Audit. But whether or not the wickedness has increased or is increasing, we are sure that it should be diminished.



TRICKS OF THE TESTING TRADE

Private testing laboratories live and die by the *positive* results generated on products they test for safety. Your future as a laboratory owner or administrator is in serious jeopardy if you find too many products unsafe. But fortunately, manufacturers rarely run their own audits on tests contracted out to private labs. That way, they can claim ignorance of wrongdoing if protocol is not followed. So here are some tricks you can use to help that drug, chemical or product meet approval standards.

THE HAPPY ENDING. Bureaucrats rarely seem to have time to read more than summaries and conclusions. So you can do your manufacturing client a great service by having the conclusion bear minimal relationship to your findings, particularly if the findings are negative. Remember that statistics are at the service of those that use them.

THE SHRED. Keep a paper shredder near your records at all times. If you hear that a government inspector or auditor is about to visit, use the shredder quickly to rid your files of embarrassing or incriminating data. For fast shredding techniques, call Industrial Bio-Test Laboratories.

THE BENCHBOOK BOOGIE. If you have to create new benchbooks to substantiate

hiring untrained technicians, you can always use them as an excuse when the scientific method is inadvertently abused or abandoned. You can contact almost any testing lab in the country in your search for undereducated, unqualified and incompetent staff. Move your staff around the lab constantly throughout experiments. If someone is leaving your firm, have that person sign all the benchbooks. That way the "responsible party" will be absent should an inspection ensue.

Keep a scalpel in your lab, a shredder near your files, and don't tell the Feds your data caught fire.

THE SPEEDUP (OR THE TIME-LINE FUDGE). Many safety tests require long exposure of the product to hostile environments like extreme heat, dryness, cold or wetness. Take semiconductors, for

on the creative use of the scalpel contact the G. D. Searle Company and ask about the tests it performed on Aldactone, a diuretic prescribed for high blood pressure and fluid retention. Or write to Syntex Corporation and ask about the research it contracted for on the antiarthritic drug Naprosyn.

THE POSTHUMOUS APPEARANCE. Should laboratory animals die, replace them with live, healthy relatives. Again, contact G. D. Searle and Industrial Bio-Test Laboratories in Chicago to learn how some of their rats, monkeys, rabbits and dogs, which died during tests, later appeared alive in test data. Animals can also be recorded as gaining weight and recovering from tumors after their death. Use your benchbook creatively.

THE DATA MASSAGE. Also known as "Graphiting," data massaging is probably the most common fudging technique used in labs today. Motivated by what scientists euphemistically call "intentional bias," it is really the easiest way to get the results you want once the experiment is completed. There is no one way to massage data. Just take those long computer reports home with you, spread them out on the kitchen table and gently apply rubber and graphite.

SOME EXTRA ADVICE: If the validity of your study is questioned, do not under any

How to buck the system — a tongue-in-cheek article by Irene Moosen and Mark Dowie which appeared in Mother Jones *in 1982. (Reproduced from* False Prophets.)

When a question arises in the science of science (a respectable discipline, the methods of which have been successfully applied to the growth of science as a whole), one would expect scientists to try to answer it scientifically. Too often, however, they fall back on dogmatic or wistful assertions of belief. If public attitudes to science were still as starry-eyed as they were even 25 years ago, such piety might suffice. But reassurances that there is nothing to worry about — because the scientific process is self-corrective, and that mistakes, deliberate or accidental, will be found out sooner rather than later — are no longer enough. Such reasoning belongs to the "tap-dancing and dinosaurs" class ("I'm tap-dancing to keep the dinosaurs away!". "But there haven't been any dinosaurs for years!". "There! You see?"). That the only examples of fraud that have been discovered are the ones that have been discovered is not likely to convince the critics of science, and should not satisfy scientists either. Even Popper considers only that errors are "fairly often, in time, corrected".

How much time is needed for the purpose? Seventeen years or so between deed and discovery in the case of Cyril Burt, or 40 for the Piltdown hoax or Gregor Mendel? There are even more important questions to ask about the ethics of scientific discovery than this, but they are seldom examined systematically. One obvious framework is: What is scientific fraud (definitions)? How much of it is there (estimates, including trends)? Why does it occur (reasons — social as well as individual)? Does it matter anyway (costs — and possible benefits: see below)? And what is being and should (or can) be done about it?

Of course, Kohn is aware of these problems but, as is common among popularizers of science, he seems to believe that readers prefer a stream of hair-raising stories to a serious discussion of ways to identify and prevent fraud in the future. Thus it would serve little purpose to quote the table of contents; the divisions between subject areas often seem to be arbitrary and the chapter titles usually promise more than the text delivers. Even though his final chapter is entitled "What Can Be Done about Fraud in Science?", and might have been expected to bring together and add to suggestions scattered about the book, it is only three pages long and one of them is taken up by introducing two further anecdotes warning would-be whistle-blowers that theirs is a very chancy and perhaps even dangerous activity.

The most relevant point is made in the very last paragraph of all: "To understand deceit in science, one has to study first the ethics of the society within which the scientists work and live . . .". A useful book on scientific fraud would begin, instead of ending, at that point. Given one society (Britain) in which the world's largest advertising agency can switch from helping a national health campaign to promoting the very product whose use it had previously sought to diminish; another (the United States) in which 25,000 unnecessary cardiac pacemakers are inserted per year; a third (the Soviet Union) in which. . . . The list can be continued to infinity.

One should not, of course, criticize an author for writing the book he wanted to write; but it is fair to suggest that Kohn has not carried out his own expressed intention. His sub-title is *Fraud and Error in Science and Medicine*, less alarmist than Broad and Wade's *Fraud and Deceit in the Halls of Science* more open-minded too. It also allows Kohn to mention Mendel and Newton more properly in his book than Broad and Wade in theirs. But though with these references, as well as elsewhere (for example, in the attractive dust-jacket of Wyck's "Alchemist") Kohn implies that error may sometimes be only an idea whose time has not yet come, the theme nowhere receives the discussion its importance requires and the title of the book promises: When is an error not an error but a flash of inspiration? Not only do our hypotheses depend upon our perceptions, but perception is itself a prisoner of hypothesis. Even good scientists have sometimes been so sure that they were right that, in Alan Franklin's words, they "manufactured data . . . until real data became available" — even one of Darsee's retracted papers has already been de-retracted!

Perhaps Kohn fails to deliver because, understandably, he is as uncertain about the matter as the rest of us. In fact, he is at times so uncertain in his handling of certainty in general — for example, the meaning of correlation, and the relationship of truth to the laws of chance; not to speak of his confusion between experimenter (or cognitive) error and experimental (or statistical) error — that the reader is sometimes driven to doubt his grasp of the matters of which he writes.

According to Stephen Toulmin, "medicine has saved the life of ethics" (*Perspectives in Biology and Medicine* **25**, 736–750; 1982), producing "spectacular and irreversible effects on the methods and content of philosophical ethics". It is high time for at least a first instalment towards repayment of the debt. ☐

The chips are now down?

Steve Woolgar

Mind Over Machine: The Power of Human Intuition and Expertise in the Era of the Computer. By Hubert L. Dreyfus and Stuart E. Dreyfus. *Basil Blackwell/ Free Press: 1986. Pp.231. £15, $16.85.*

THE most important and exciting thing about artificial intelligence (AI) is that it provides the possibility of a critical test of fundamental assumptions about the nature of knowledge and reason. These assumptions have gripped Western thought for 2,000 years and they underpin ingrained ideas about the character of man, his abilities and potential. If the project to devise artificial reason is adjudged a success, it will vindicate the objectivist and rationalist philosophies which are thought to have guided the rise of science and technology; its failure will buttress those phenomenological and intrepretivist philosophies which argue that calculation and measurement are largely irrelevant to man's capacity for intelligent behaviour.

Hubert Dreyfus recognizes what is at stake. His *What Computers Can't Do*, first published in 1972 and revised in 1979, was a compellingly sophisticated analysis of the philosophical assumptions which underlie AI. That book provided an overview of developments in AI from work on cognitive simulation in the 1950s to early attempts at knowledge engineering in the 1970s. *Mind Over Machine*, written with his brother (a computer specialist), extends the analysis to recent work, particularly on expert systems. The book's appearance is timely, in view of the sudden and massive increase in financial support for AI, especially from military sources.

Will these people collect on their expensive bet? The Dreyfuses say no. Their central thesis is that intelligent human behaviour (interpretation, understanding, recognition, puzzle solving, rule application and so on) is simply not amenable to formalization in the way required by digital computers.

The authors propose a model comprising five stages of skill acquisition, ranging from novice to expert. Progression beyond the third stage ("competence") requires a qualitatively different approach to reasoning. Expertise, in their view, involves the accumulation of experience, the unconscious holistic recognition of the familiarity of new situations and the critical use of intuition and "know-how". This is beyond the ability of systems designed on principles of calculation from discrete facts and codified rules. The apparent success enjoyed by some artificial devices occurs in restricted (artificial) areas which require competence rather than intelligence. This is not to deny the usefulness of some AI systems as aids, but such systems are properly termed "competent" rather than "expert". The five-stage skill hierarchy is used to discern the limits of computer use both in education and in managerial decision-making. Only in the rare instances, where researchers abandon the mechanistic models of human skill, do we find hope for a better approximation to human expertise.

The anti-mechanistic view of human skill derives from the Wittgensteinian argument that the determination of interpretation, understanding, recognition and so on is entirely construed in a social context and can never sensibly occur in isolation from it. But the Dreyfuses' hierarchy of skills is strikingly individualistic and mentalistic. For example, they characterize expertise in terms of inner processes: "the expert driver becomes one with his car, and he experiences himself simply as driving, rather than as driving a car . . ." (p.30). Given the philosophical orientation of their critique, there is surprisingly little acknowledgement of the way in which such experiences are meaningful only as socially sanctioned and publicly accountable descriptions. Although the authors insist that their aim is not to mystify, their treatment of skills as inner processes and experiences provides too easy a target for the rationalists. Similarly, it is surely offering too much of a hostage to fortune to continue to speak of the brain and the mind as receptacles of intelligence. The Dreyfuses intend these curious and outdated concepts as a sanctuary for unformalizable human skills. But as others such as Jeff Coulter have shown, notions of "brain" and "mind" are social constructions which tend to support the mechanistic view of human behaviour.

"IT FIGURES. IF THERE'S ARTIFICIAL INTELLIGENCE, THERE'S BOUND TO BE SOME ARTIFICIAL STUPIDITY."

Cartoon by Sidney Harris

The Dreyfuses are especially impressive in demonstrating that despite changes in emphasis and direction (for example, the shift from attempts to fashion general, problem-solving devices to those able to make inferences within a highly specialized knowledge domain), workers in AI repeatedly face the same fundamental conceptual problems. For the Dreyfuses, AI's failures are the direct result of such irresolvable problems. For many AI enthusiasts, however, these are merely temporary, technical and surmountable difficulties. For example, whereas the Dreyfuses say that work on "expert" systems shows it is wrong to assume that human experts are using heuristic rules, proponents of AI interpret the research as merely indicating some snags in eliciting these rules. (It is notable that most previous responses to Hubert Dreyfus's ideas have preferred to contest the alleged failure of particular systems, rather than address the conceptual problems he raises.)

Early restricted successes gave rise to unwarranted optimism about the future of AI and, for the Dreyfuses, this optimism partly accounts for the current inability of the AI community to recognize failure. But the Dreyfuses also suggest that the stakes are now so high that failure is actively concealed. They thus allege deliberate cover-up by the AI establishment, describing in the book their own treatment and the manipulation of TV appearances by the "artificial intelligentsia", and criticizing the "unscientific" attitude of AI workers. (The dust-jacket speaks of "AI's record of barefaced public deception".)

This recourse to a kind of conspiracy theory is something of a distraction. For a full appreciation of the dynamics of the AI enterprise, we need to look carefully at the social attribution of "success" and "failure" in the context of a pervasive commitment to rationalistic models of intelligence. Although the Dreyfuses' conceptual argument provides a good, sceptical springboard from which to launch a social analysis of AI research, we should avoid their supposition that conceptual problems will necessarily give rise to "failures".

Who, in any case, are those who cover up failures and spread false optimism about AI? It is important to be clear that the Dreyfuses identify a relatively small body of researchers. True, these are the most influential and respected champions of AI and are thus a legitimate and necessary target for attack; many are entrepreneurs with a substantial interest in furthering public support for the enterprise. But it might be misleading to accept their proclamations as characteristic of AI as a whole. Searle's distinction between "strong" and "weak" AI is useful here. Whereas proponents of strong AI (who claim, for example, that programs can "understand") are appropriate targets for the Dreyfuses, the more cautious advocates of weak AI (who see computers as, at best, a tool for aiding our investigations into the nature of intelligence) might agree that it is unreasonable to expect the success of artificial systems beyond the level of competence.

Weak and strong AI are not unrelated, of course. Proponents of the former have undoubtedly benefited from the public persuasiveness of the latter. But the distinction points to a further shortcoming in the Dreyfuses' case. By concentrating upon proponents of strong AI, the arguments give us little insight into what practitioners of AI do. In this book, the Dreyfuses continue their impressive assault in the titanic struggle between phenomenological philosophy and the rationalist assumptions of AI's public guardians. But we are not told whether or how the assumptions of strong AI touch upon the day-to-day business of devising systems, making programs work, evaluating output and so on.

It is interesting to consider the likely fate of the Dreyfuses' thesis. Their case against AI is the strongest and most eloquent yet published, a protest against conceptions of the human being which have held sway since the beginnings of Western thought, and it suggests that one outcome of the AI debate might be a definitive refutation of the rationalist metaphysic. However, the lack of a fully social conception of the practice of machine intelligence is perhaps reflected in their inattention to one of the key lessons of the history of science: "critical tests" are rarely decisive. Evaluations of "success" and "failure" need only generate further redefinitions of AI, not its abandonment. ☐

Wondrous gifts

Peter Bryant

Nature's Gambit: Child Prodigies and the Development of Human Potential. By David Henry Feldman with Lynn T. Goldsmith. *Basic Books:1986. Pp.259. $19.95.*

EVERY now and then a child turns out to be outstandingly talented in a quite specific way. It is not just that he quickly outstrips all his contemporaries in a particular skill: he also soon becomes a great deal better than most grown-ups at it. Children such as this arouse great interest and wonder. Psychologists in particular have to pay attention to them because at first sight they seem to break most of the rules set out by developmental theories. After all, these theories generally hold that different intellectual skills are connected and that they develop together at roughly the same pace through childhood. How can such theories possibly explain a five-year-old child whose mathematical skills already outstrip those of 95 per cent of the adult population, but who otherwise seems pretty ordinary?

I suspect that this question was the starting point for David Feldman's book, which is a prolonged and detailed study of six different, prodigiously talented American boys and their families, but it is not in the end a question that he answers satisfactorily. Instead he spends most time on another question which is unanswerable, or at any rate cannot be answered from a study of individual child prodigies. His main concern is to find what conditions are needed to produce such children. Feldman's own idea, which is about what he calls the "coincidence process" is neither new nor sophisticated: it is that these children have extraordinary gifts ("proclivities" is Feldman's term) to start with but that their talents only flourish in the right environment. Prodigies need sensitive and devoted parents and an appropriate social environment, according to Feldman, and he is plainly impressed by the lengths to which some of the parents in his little group were prepared to go to support their children. Sacrificing jobs, commuting long distances, confronting awkward teachers, taking the child from one tutor to the next — these seem to be typical demands for a prodigy's parents, and in this group at least they shouldered the burden quite cheerfully. Often the parents' own talents matched their child's: the boy with an extraordinary gift for music had a musician for a father, and the father of the boy who showed early signs of being a talented writer was a writer himself. In these cases the parents spent a great deal of time teaching their own specific skill to their child.

Feldman's argument that all the children in his group were lucky enough to be born into a suitable environment is convincing, but it does not prove his case that such environments are essential for the emergence of a prodigy. The trouble is that his thesis is just as much about children whom he did not study as about the six prodigies with whom he spent so much time. There must, he argues time and again, be children who could have been prodigies, who had the "proclivities", but who found themselves in the wrong environment: the world must be littered with mute, inglorious Miltons or Cromwells guiltless of their country's blood. But Feldman did not study any such prodigy *manqué*. He does not even demonstrate that they exist, and it is very difficult to see how he could have done so, given his methods.

Making music — the prodigiously talented Mozart, accompanied by his father and sister.

Feldman's description of the lives of the six boys is interesting and frequently poignant: but it is difficult to see what is new here. After all, we already know a great deal about the childhood of erstwhile prodigies. Mozart's childhood, to take one example, is documented as well as any other part of his life. Sartre, to take another, wrote about his early years in great detail and with considerable distaste. One of the most striking features of these examples and the children studied by Feldman is the surprise and interest that the prodigies excited in the adults around them. The children soon become performers and they do so at the insistence of adults. On occasion, adult astonishment at the child's unexpected talents has some odd results. In my view the most interesting part of Feldman's book is his description of the way in which parents or teachers sometimes resort to irrational explanations for a child's extraordinary talents, because they cannot account for them in any other way. Reincarnation is one solution. The child is thought to be so talented because he is simply a new version of a dead genius.

To read Feldman's sympathetic and sensitive accounts of these six children is to feel the same kind of awe which the young Mozart must have inspired in those who heard him play and improvise so effortlessly. Readers of this book will wonder at the phenomena which Feldman describes, but will remain puzzled about the reasons for them and about the implications for developmental psychology. ☐

Knockabout stuff

Derek Ager

The Tenth Muse: The Pursuit of Earth Science. By Ronald B. Parker. *Charles Scribner's Sons: 1986. Pp. 221. $15.95.*

THE nine official muses were responsible for literature, art and a limited amount of science. They had originally been three in number, but six more were conceived and so it is reasonable to add another to represent geology, the most beautiful and inspiring of the sciences. Professor Parker, however, obviously nominates the subject for its entertainment value rather than for its aesthetic qualities.

We are all interested chiefly in our own ideas, but Professor Parker's egocentricity is particularly evident. He assumes that we have read his previous book, and tells us how his great "buffer" idea came to him and how the audience reacted to it at various lectures. Personally I do not understand the "buffer" terminology which is central to most of Dr Parker's thoughts, and would have thought that a better metaphor for what he discusses (the storage and sudden release of energy) would have been the elastic band, which can be stretched so far before suddenly breaking.

Parker's main interest is in our geological today and yesterday — geysers and landslips, glaciers and ice dams. In "The Urge to Surge", for example, he discusses the movement of glaciers and their episodic behaviour, making an assignation with the reader up in Alaska around the year 2000 when things are due to get moving again.

In an excursion into his other main field, crystallography, Parker points out that this science originated in the West, where symmetry is taken for granted, and not in the East where the Zen philosophy prefers asymmetry, be it in gardens or pottery. He goes on to discuss man and other "non-crystallographic" forms in the world (with a delightful independence of thought, he and his wife built themselves a 14-sided house), and Schechtman's discovery of the impossible, that is to say, five-fold symmetry in crystals, as a salutary warning of the need for his own kind of open-mindedness. As a palaeontologist I should point out that echinoderms came up with five-fold symmetry first, albeit using trigonal calcite crystals.

There is a boyhood trip to Boron, site of the largest borate mine in the world, before an essay on "coral clocks" and organic growth generally. Here Parker regrets that corals, with their daily growth-lines, are rare as fossils compared with "clams", thereby displaying a surprising ignorance of the Palaeozoic part of the record. He obviously prefers the "clams" (including their suitability for feeding the poor graduate students studying them), and shocks the palaeontologist by referring to the brachiopods as their "look-alikes". All of this makes me prefer Parker as a geomorphologist and crystallographer rather than as a palaeontologist–stratigrapher.

So we go on to "Aqua Spectaculars and Other Disasters", ranging from Esther Williams and her symmetrical swimmers in those boring films of the 1930s, and via an extremely tenuous link to tsunamis and catastrophically emptying lakes, such as Lake Bonneville and, of course, J. Harlen Bretz's spectacular Lake Missoula. And so back to the "buffer" phenomenon (or better perhaps the knicker elastic of the same vintage as Professor Parker's films) in the building and release of energy in eruptions ranging from Mount St Helen's to Santorini.

There is, too, a general discussion of fossil "scat" (excreta to British readers), including description of a remarkable concentration of three billion tons of apatite in the Kola Peninsula which *might* have been the result of a monstrous ball of dung hitting the Earth. More seriously, we are told that from the evidence of their "scat" the giant ground sloths may have become extinct from a drug overdose, through eating the plant known as "Mormon tea". So the book goes on, leaping nimbly from one unlikely topic to another — remote sensing to salt "punch-ups", karst erosion to mass extinctions, until finally reaching the geological glory of field-work in (where else for a muse?) the Elysian Fields.

This is an enjoyable book, a cheerful somersault rather than a solemn symposium and better for entertainment than for education. But that, presumably, was the author's intention. □

Wilder shores

Peter J. Smith

Islands. By H. W. Menard. *W. H. Freeman: 1986. Pp.230. £15.95. In the United States available only to members of the Scientific American Library.*

THERE seem to be as many books called *Islands* as there are islands, concentrating on everything from scenery, through seafaring and survival, to science. Menard's version falls into the last category, as one might expect from a distinguished geological oceanographer who ended up as Director of the US Geological Survey. But a scientific book on islands sounds a bit like one on kidneys; one can see the attraction of specialization whilst taking leave to doubt whether much sense can be made of the parts in isolation from the body as a whole. As far as the Earth sciences are concerned, the revolution of the 1960s, which produced the first convincing global theory of the Earth's behaviour, placed islands firmly in the context of spreading sea-floors and jostling tectonic plates, from which conjunction they are never likely to escape.

Inevitably, therefore, Menard has ended up writing a book largely about plate tectonic processes, albeit with islands taking centre stage and with little mention of continents. Excluded too, incidentally, are those islands, large or small, with a continental structure (Britain, New Zealand, Japan, the Seychelles, certain Indonesian islands and so on). Menard's islands are oceanic — volcanic or volcanic/coral, "small, young, isolated, simple, and subjected to a limited range of environmental factors". In geological terms they represent the closest that nature comes to laboratory conditions, with dependent variables at a minimum.

Notwithstanding the restricted definition, there is a surprising amount to say. For one thing, islands are perpetually under the influence of spreading lithosphere and stationary hot spots, and all that means in terms of aging, subsidence, rates of extrusion, distribution, redistribution and, ultimately, subduction, continental underplating or terrane formation. New volcanic masses lead to isostatic adjustments and lithospheric warping, the effects of which can be obscured by multicausal changes in sea level. Then there is the whole phenomenology of underwater volcano formation and decay, involving magma flow, growth rates, erosion and submergence, with or without the participation of coral. Finally, the issue of colonization raises important questions about evolution, migration and civilization.

Plate tectonics though much of this may be in essence, it is plate tectonics viewed obliquely. It does no harm at all to be forced to look at familiar concepts from an unusual angle as long as the viewpoint is coherent, which is Menard's hands it certainly is. The level could best be described as *Scientific American*, which means that the absolute novice may find it tough going in parts. Those with a smattering of basic terminology, however, will discover a rewarding and unusually enjoyable volume, not at all a bad memorial to an Earth scientist who was ever ready to look beyond his immediate research. □

Peter J. Smith is Reader in Earth Sciences at the Open University, Walton Hall, Milton Keynes MK7 6AA, UK.

- Another of Henry Menard's books to be published posthumously, *The Ocean of Truth: A Personal History of Global Tectonics* (Princeton University Press), will be reviewed in a future issue of *Nature*.

New Books from IRL Press

THE PRACTICAL APPROACH SERIES

Carbohydrate Analysis

Edited by M F Chaplin and J F Kennedy

Although there is a vast literature covering numerous carbohydrate analytical methods, it is not always obvious to the researcher which method, or even physical technique, is the most appropriate to a particular investigation. *Carbohydrate Analysis* answers the need for a handbook of laboratory protocols in this field. It brings together the proven techniques, compares their merits in different situations, and then provides full practical details of the most suitable methods within those techniques.

Due November 1986; approx 240 pp;
Soft 0 947946 44 6; £16/US$29
Hard 0 947946 68 3; £26/US$47

Spectrophotometry and Spectrofluorimetry

Edited by D A Harris and C L Bashford

Biochemists who use this new book will see clearly how spectrophotometry can contribute to laboratory analyses – what is required in the experimental set up and how the information obtainable should be optimized. Researchers and clinicians will find the detailed protocols and thorough introduction to the use of fluorimeters and spectrophotometers invaluable, particularly if they are using them for the first time or with only a rudimentary knowledge. Technicians carrying out routine analyses will also benefit from this laboratory handbook.

Due November 1986; approx 186pp;
Soft 0 947946 46 2; £16/US$29
Hard 0 947946 69 1; £26/US$47

Biochemical Toxicology

Edited by K Snell and B Mullock

Describes the most useful and recent procedures available for biochemical toxicology. Particular emphasis is given to the application of general biochemical techniques to toxicological research. Experienced toxicologists offer not only details of protocols, but also their all-important 'tricks of the trade', which are often omitted from research papers.

Due December 1986; approx 256pp;
Soft 0 947946 52 7; £16/US$29
Hard 0 947946 67 5; £26/US$47

Nucleic Acid and Protein Sequence Analysis

Edited by M Bishop and C Rawlings

The determination of nucleic acid and protein sequences is a technique fundamental to molecular biology and biotechnology. This new book describes practical methods using computer analysis in the following areas: experimental determination of restriction maps and DNA sequences, predicting DNA function, predicting RNA and protein folding, searching databases for homologous sequences and making inferences about molecular evolution.

Due December 1986; approx 360pp;
Soft 1 85221 006 0; £16/US$29
Hard 1 85221 007 9; £26/US$47

Pre-Publication Prices

Prices quoted are valid for all pre-paid orders received before 31 December 1986. Thereafter prices may vary.

COMPLETE CATALOGUE AVAILABLE ON REQUEST

US$ prices valid in North and South America and Japan, £ prices elsewhere. All orders sent direct to publisher should be prepaid – publisher pays postage. Orders received without payment will be first invoiced to customer and postage added. Payment must be received before books are despatched.

Plasmids

Edited by K G Hardy

Provides all the essential methods for studying bacterial plasmids with emphasis on the most up-to-date and proven methods. Written by acknowledged experts, the chapters have been chosen for their central importance or because they provide unique descriptions of methods for areas of study currently undergoing rapid development. An essential source book for advanced courses in microbial genetics and for laboratory research.

Due December 1986; approx 240 pp;
Soft 0 947946 81 0; £16/US$29
Hard 0 947946 82 9; £26/US$47

Teratocarcinomas and Embryonic Stem Cells

Edited by E J Robertson

Embryonic stem cell cultures are now widely used as an experimental model system by investigators sharing diverse primary scientific and clinical interests. This new book describes both the basic, routine techniques and the specialist techniques associated with this experimental system. Provides in-depth coverage of the practical aspects of cultivated stem cell lines, include the more recently developed techniques for isolation of murine pluripotent stem cells (ES or EK cells).

Due December 1986; approx 256pp;
Soft 1 85221 004 4; £16/US$29
Hard 1 85221 005 2; £26/US$47

ALSO OF INTEREST

Molecular Medicine Volume 2

Edited by A D B Malcolm

Applications to clinical practice of recent advances in tissue and organ biochemistry.

Contents:
Hyperthermic therapy and heat shock response *R H Burdon* • The molecular genetics of lipid metabolism *J Scott* • Blood coagulation and its abnormalities *I Peake and M Liddell* • Vaccine design: A challenge to molecular biology *M Mackett.*

Due December 1986; approx 180pp;
Soft 0 947946 58 6; £16/US$29

Biological Monitoring of the State of the Environment: Bioindicators

IUBS monograph series no 1
Edited by J Salanki
Due October 1986; 80pp;
Soft 1 85221 015 X; £12/US$20

Biological Nomenclature Today

IUBS monograph series no 2; papers presented at ICSEB III; held in Brighton, UK; 9 July 1985.
Edited by W D L Ride and T Younes.
Due October 1986; 80pp;
Soft 1 85221 016 8; £12/US$20

Autumn books

Fundamentals of Immunology

By **O. G. Bier, W. Dias da Silva, D. Götze, I. Mota**

With a contribution by R. Burger

2nd, completely revised edition. 1986. 173 figures. Approx. 480 pages. Soft cover DM 64,–. ISBN 3-540-15332-2

"The book's stated aim is to provide an introduction, primarily for medical and biology students, as a foundation for subsequent reading. It does this certainly, and with a clarity, sense of purpose and economy that is not achieved in many other recent texts." *immunology today*

F. Vogel, Heidelberg; **A. G. Motulsky**, Seattle

Human Genetics

Problems and Approaches

2nd, completely revised edition. 1986. 447 figures, 210 tables. XXXIV, 807 pages. Hard cover DM 148,–. ISBN 3-540-16411-1

"This book should be read by all who work in human genetics and who teach it to others. It should be read by all advanced students in genetics, human or otherwise, and it should be read – or at least the nontechnical parts of it – by those outside the field who would like insight into the way human genetics and human geneticists work…" *American Journal of Human Genetics*

J. C. Rüegg, University of Heidelberg

Calcium in Muscle Activation

A Comparative Approach

1986. Approx. 97 figures. Approx. 320 pages. (Zoophysiology, Volume 19). Hard cover DM 198,–. ISBN 3-540-17117-7

This monograph presents a unifying picture of the control of calcium movements and calcium action in smooth, cardiac, and skeletal muscle.

E. Gwinner, Andechs

Circannual Rhythms

Endogenous Annual Clocks in the Organization of Seasonal Processes

1986. 73 figures. XI, 154 pages. (Zoophysiology, Volume 18). Hard cover DM 128,–. ISBN 3-540-16891-5

Contents: Introduction. – Evidence for Circannual Rhythms. – Properties of Free-Running Circannual Rhythms. – Synchronization of Circannual Rhythms. – Mechanisms of Circannual Organization. – Adaptive Significance of Circannual Rhythms. – Appendix: General Oscillator Model and Terminology. – References. – Systematic Index. – Subject Index.

E. Koushanpour, Northwestern University; **W. Kriz**, University of Heidelberg

Renal Physiology

Principles, Structure and Function

2nd edition. 1986. 193 figures, 3 color plates. XII, 390 pages. Hard cover DM 124,–. ISBN 3-540-96304-9

This second revised edition presents an integrated and quantitative analysis and synthesis of the subjects of fluid and electrolytes, kidney structure and function, acid-base balance, and their regulation under normal conditions. The purpose of this book is to provide the latest comprehensive information about the above subjects for those interested in the general field of nephrology.

Small-Bowel Transplantation

Experimental and Clinical Fundamentals

Editors: E. Deltz, A. Thiede, H. Hamelmann, Kiel

1986. Approx. 400 pages. Hard cover DM 180,–
ISBN 3-540-16336-0

For the first time, the results of all groups of scientists working in the new field of small bowel transplantation are compiled in one volume. The book provides fundamentals, including animal models, immunology, and immunosuppression, as well as a stimulus for progressive work in the basic sciences, such as transplantation immunology and its application to in vivo models. Operative techniques and indications for small bowel transplantation are discussed in detail, and suggestions for clinical application are given.

Central Action of ACTH and Related Peptides

Editors: D. de Wied, University of Utrecht;
W. Ferrari, University of Modena

1986. VIII, 240 pages. (FIDIA Research Series).
Hard cover DM 175,–. ISBN 3-540-96367-7
Distribution rights for Italy: Liviana Press, Padova

A. Labhart, University of Zürich

Clinical Endocrinology

Theory and Practice

2nd, completely revised edition. 1986. 416 figures. Approx. 1125 pages. Hard cover DM 360,–. ISBN 3-540-15462-0

"The photographs, tables and diagrams are an outstanding feature of this work. One can only state that this book is far in advance of its competitors and will readily alter the habits for those who require a standard reference text in endocrinology." *Gynecological Investigation*

Springer

T. M. Fenchel, University of Aarhus

Ecology of Protozoa

The Biology of Free-living Phagotrophic Protists

1986. 47 figures. Approx. 200 pages. (The Brock/Springer Series in Contemporary Bioscience). Hard cover DM 94,– ISBN 3-540-16960-1
Distribution rights for the USA, Canada and Mexico: Science Tech, Inc., Madison, WI

Here is a comprehensive treatment of the functional biology, ecology, and natural history of free-living protozoa. Emphasis is placed on the importance of protozoa in the food chains of natural ecosystems, and this role is discussed within the framework of the functional properties of these organisms.

J. Brachet, H. Alexandre, Free University of Brussels

Introduction to Molecular Embryology

2nd, totally revised and enlarged edition. 1986. 77 figures. Approx. 240 pages. (Heidelberg Science Library). Soft cover DM 39,–. ISBN 3-540-16968-7

Contents: From Descriptive to Molecular Embryology. – How Genes Direct the Synthesis of Specific Proteins in Living Cells. – How Eggs and Embryos are Made. – Gametogenesis and Maturation: The Formation of Eggs and Spermatozoa. – Fertilization: How the Sleeping Egg Awakes. – Egg Cleavage: A Story of Cell Division. – Molecular Embryology of Invertebrate Eggs. – Molecular Embryology of Amphibian Eggs. – Molecular Embryology of Mammals. – Biochemical Interactions Between the Nucleus and the Cytoplasm During Morphogenesis. – How Cells Differentiate.

Concepts in Viral Pathogenesis II

Editors: A. L. Notkins, Bethesda, MD; **M. B. A. Oldstone**, La Jolla, CA

1986. 31 figures, 12 tables. XX, 428 pages. Hard cover DM 110,–. ISBN 3-540-96322-7

This extension of the well-received first volume is in the same format with 61 minireviews by leading researchers on new topics in viral structure and function, oncogenes, viral immunology, human disease, and antiviral vaccines. It offers ready access to current knowledge on one of the most important and rapidly developing subjects in biomedical science today.

By the same editors:

Concepts in Viral Pathogenesis

1984. 26 figures. XVIII, 409 pages. Hard cover DM 106,– ISBN 3-540-90982-6

The Changing Environment

1986. 40 figures. X, 239 pages. (Springer Series on Environmental Management). Hard cover DM 86,– ISBN 3-540-96314-6

Contents: Introduction. – Environmental Issues in Less Developed Countries. – Environmental Management in Developed Countries. – Hazardous Waste. – Ground Water Contamination. – Toxic Substances in Water. – Toxic Particulates in Air. – New Fossil Fuel Technologies. – Nuclear Energy. – Acid Deposition. – Index.

Smiths' Sea Fishes

Editors: M. M. Smith, Grahamstown; **P. C. Heemstra**, Washington, D.C.

6th edition. 1986. Approx. 1800 figures, 144 colour plates. XX, 1047 pages. Hard cover DM 198,–. ISBN 3-540-16851-6 (Originally published by the Trustees of the Sea Fishes of Southern Africa Book Fund)

Describes all important aspects of the fishes of the South Atlantic and the Indian Oceans. Its wealth of colour and black-and-white illustrations facilitate the quick identification of a species and convey the beauty of the living specimen.

Ecophysiology of Spiders

Editor: W. Nentwig, University of Regensburg

1986. Approx. 133 figures. Approx. 465 pages. Hard cover DM 278,–. ISBN 3-540-17034-0

Ecophysiology encompasses the wide range of physiological characteristics that determine the ecology of a species, thus providing a suitable framework for this first book on spider physiology. Experts have written short reviews and original research reports on such diverse topics as thermal relationships, gland physiology, feeding ecology, parasites, and biorhythms.

A Genetic Switch: Gene Control and Phage λ

M. **Ptashne**, Professor of Biochemistry and Molecular Biology, Harvard University

A Genetic Switch has been written by one of the most eminent names in the field of molecular genetics as an introduction to gene function - specifically the genetic repressor. Understanding the repressor function is essential to an understanding of biochemical activity within the gene as it is fundamental to the process by which growth and development are regulated at the molecular level. The book is intended as a basic introduction to repressor function for both advanced and undergraduate and graduate level courses in genetics and biochemistry. It will also be essential reading for researchers and students of phage, viral and general genetics.

1986. 138 pages, 20 illustrations. Paper, £14.95
0 86542 315 6 *Blackwell*

Essential Genetics

P. J. Russell BSc, PhD, Associate Professor of Biology, Reed College, Portland, Oregon

Early 1987. 326 pages, 277 illustrations. Paper, about £13.50
0 632 01602 7 *Blackwell*

In this book, based on an earlier book by the author in the *Lecture Notes* series, this exciting and fast moving field is condensed into a brief but balanced review. Principles of genetics are presented in an up to date and readable way, together with an explanation of both classical and modern genetics experiments which enable the reader to gain an understanding of the methodology of genetics. The format is logical and concise, with chapters on the molecular aspects of genetics, transmission genetics, regulation of gene expression, and extranuclear inheritance. Topics of particular interest included are a discussion of rapid DNA sequencing and gene cloning, regulation of gene expression, the action of steroid hormones and a discussion of the genetics of populations. Each chapter contains exercises for the student, with answers supplied at the end, and there is a useful glossary for quick reference.

To Appear in 1987

An important new forum for researchers in this multidisciplinary field . . .

Journal of Paleoclimatology

Editors
Alan D. Hecht, *NOAA, 11400 Rockville Pike, Rockville, MD20852, USA*
Tom M. L. Wigley, *Climatic Research Unit, University of East Anglia, Norwich, NR4 7TJ, Great Britain*

Scope

The *Journal of Paleoclimatology* (JPC) provides a focus for all aspects of research in paleoclimatology, a common meeting place for the otherwise widely dispersed disciplines that contribute to this multidisciplinary field. Original work on virtually any aspect of paleoclimatology falls within the scope of the journal. New paleoclimatic evidence from all forms of proxy data on all time scales will be welcome. JPC aims to encourage new techniques for the quantification of proxy climatic data, new methods of analysis and interpretation, and the use of numerical climate models, particularly where this leads to a better understanding of the causes of climatic change.

Feathered flights of fancy

Tom Kemp

Archaeopteryx, The Primordial Bird: A Case of Fossil Forgery. By Fred Hoyle and Chandra Wickramasinghe. *Christopher Davies, PO Box 403, Sketty, Swansea SA2 9BE, UK:1986. Pp.135. £10.95.*

THE eminent British astronomers Fred Hoyle and Chandra Wickramasinghe have greatly exercised the vertebrate palaeontology community with their assertion that the famous reptile/bird fossil, *Archaeopteryx*, is a fake. If true, the claim would match the enormity of the fraud associated with Piltdown man. Never having studied any of the specimens of *Archaeopteryx*, nor staked my reputation upon its genuineness, I can cheerfully accept the possibility in principle. Briefly, what is supposed to have happened is that the fossil of a small dinosaur was taken, shallow areas of matrix gouged out and replaced by a paste made from ground-up matrix, and then modern feathers pressed onto the paste to create the imprints now seen.

The authors go about the task of proving their theory with all the comprehensive enthusiasm of fictional detectives, although of the Inspector Clouseau rather than Sherlock Holmes variety. For, whether through perversity or stupidity I do not know, they exhibit a staggering ignorance about the nature of fossils and fossilization processes. Others have commented in detail on the exact misunderstandings (see the paper by A. J. Charig *et al.* in *Science* **232**, 622–626;1986). In general terms, Hoyle and Wickramasinghe draw our attention to such points as changes in the texture and coloration of different parts of the matrix, failure of the part and counterpart slabs to match precisely, the "impossibly" large areas of feather impressions exposed on the slab and the "double impression" of some of the feathers. These are illustrated by the excellent photographs, although not always as convincingly as the text claims. The point is, however, that if features such as these are taken as evidence for forgery, then I do not believe that I have ever seen a genuine vertebrate fossil in my life! They all reflect quite common, perfectly explicable aspects of the process of formation of a fossil.

Two things interest me about this otherwise worthless book: why it was written, and what effect it might have. The motive seems to relate to the authors' own theory of evolution, described very briefly in the first chapter. It seems that major evolutionary change occurs as a result of "genetic storms", whence showers of virus particles from outer space invade the Earth and become incorporated into the genomes of living organisms. That this theory blithely ignores the multitude of anomalies it creates out of phenomena at present perfectly well explained by conventional theory is set aside, despite the glib invocation of Occam's razor. Apparently, periods of mass extinction as well as major evolutionary change result from large genetic storms, and therefore the origin of a group such as the birds must have coincided with a mass extinction. The nearest relevant-looking mass extinction was at the end of the Cretaceous; therefore there could not have been any birds in the Upper Jurassic; therefore *Archaeopteryx* must be a fake (and the toothed birds of the Cretaceous misidentified to boot). To support this conclusion the most outrageously improbable conspiracy theory has to be invoked. For more than a century palaeontologists seem to have been involved in a Watergate style cover-up; heavy hints that the present staff of the British Museum (Natural History) are still cheating and lying are not excluded. Do astronomers really apply this standard of reasoning in their own field?

As to the effect of the book, I am afraid that it has a superficial appeal and will undoubtedly gain currency amongst Creationists ("Now that we know *Archaeopteryx* to be a fake..."). Thus will science, the scientific method and the cultural importance of trying to understand our world suffer yet another blow. At best this book is mischievous; at worst it might well be described as evil, because it betrays that morality of objectivity that science cherishes. Perhaps *Archaeopteryx* is a fake. Certainly the possibility should be investigated. But it should be done by those who actually understand fossils, fossilization and fossil preparation, not by a couple of people who exhibit nothing more than a Gargantuan conceit that they are clever enough to solve other people's problems for them, when they do not even begin to recognize the nature and complexity of those problems. ☐

Tom Kemp is Curator of the University Museum, Parks Road, Oxford OX1 3PW, UK, and a Lecturer in the Department of Zoology, University of Oxford.

Ornithology from Princeton

A Guide to the Birds of Colombia
Steven L. Hilty and
William L. Brown
Plates by *Guy Tudor*
H. Wayne Trimm, John Gwynne, Larry McQueen, John Yrizarry, and *P. Prall*
Line Drawings by *Michel Kleinbaum* and *John Gwynne*

Describing all of Colombia's birds, Steven Hilty and William Brown bring together information on one of the world's largest avifaunas — nearly 1,700 species. Over half of all the species of birds in South America are included, thus making the book useful in regions adjacent to Colombia, as well as in the country itself.

836 pages. 56 color plates, 13 halftone plates, 99 line illus., 2 maps. Paperback edition sewn for extra strength.
P: $42.50. C: $95.00

Birds of New Guinea
Bruce M. Beehler, Thane K. Pratt, and *Dale A. Zimmerman*
Illustrations by *Dale A. Zimmerman* and *James Coe*

This book is the first definitive ornithological field guide to New Guinea, the world's second largest island and one of the richest tropical environments in the Old World. Because of its isolation, New Guinea's biota includes spectacular radiations of unusual plants and animals (of which the birds of paradise are perhaps best known). This book treats all of the more than 700 species of birds recorded from the region, illustrating more than 600 of them in forty-seven fine color plates and eight black-and-white halftone plates.

293 pages. 47 color plates, 8 halftone plates, 16 line illus., 4 maps plus endpapers. Paperback edition sewn for extra strength.
P: $37.50. C: 65.00

Putting flesh onto the bones

Malcolm C. McKenna

Mammal Evolution: An Illustrated Guide. By R. J. G. Savage and M. R. Long. *British Museum (Natural History)/Facts on File:1986. Pp.264. £17.50, $35.*

For most fossil mammals, dry bones have been brought to life inadequately by professional palaeontologists. Among extinct animals, the dinosaurs have stolen most of the limelight, and much of the rich store of research-level information about mammalian evolution reaches the public only as background material to the latest discoveries of rival anthropologists. Although there is a great story to tell about mammalian evolution, and a great opportunity to discuss how the scientific method can be applied to the subject, the good books on mammalian evolution over geological time have long been out of print or are badly outdated. Palaeontologists are bombarded by requests about the appearance in life of extinct mammals, and how they changed with time, but we possess few attempted reconstructions to show to the public; those that we do have are generally clones of previous attempts. Although professionals sometimes wince at reconstructions of fur colour patterns and other indefensible extrapolations from what is actually preserved in the fossil record, such images are undeniably useful for non-specialists. Life is breathed into the subject.

In this book, Michael Long (artist) and R. J. G. Savage (palaeontologist) do bring the evolution of mammals to life, from their poorly known beginnings in the Mesozoic to the richly known record of the Cenozoic. The book combines evocative restorations with spritely text. Many of the illustrations are new and plausible reconstructions of unfamiliar beasts; others clearly owe a debt to previous renderings. Some are outrageously funny, such as the human-faced *Thylacosmilus nicki*, or the contrite *Gigantopithecus* and wistful *Lystrosaurus*. The text is well written and pitched at the right level to maintain interest, mixing solid information with interesting references and speculation. It starts with a quotation from Shelley's *Prometheus Unbound* and ends with Dale Russell's silly illustration of a hypothetical ET-like "dinosauroid hominid". Between these there is much food for thought for non-specialists. There are a number of minor errors, but these can be weeded out for the future editions that will surely follow.

Our understanding of mammalian evolution is itself evolving, as more complete specimens are found and, perhaps more importantly, as methods of analysis improve. Although I found the book rewarding, one criticism is that the authors have missed the chance to move up from Kiplingesque scenarios to epistemologically more mature ground. After all, the British Museum (Natural History) is leading the way in injecting scientific method into its exhibits about evolution. To complement that effort, the book could have moved from exciting animals to greater emphasis on exciting problems. ☐

Malcolm C. McKenna is Frick Curator in the Department of Vertebrate Paleontology, American Museum of Natural History, New York, New York 10024, USA.

Edges of knowledge

A. Hallam

Controversy in Victorian Geology: The Cambrian–Silurian Dispute. By James A. Secord. *Princeton University Press:1986. Pp.363. $49.50, £33.10.*

Though geologists for the most part do not exhibit much interest in the history of their subject, there are few, in Britain at least, who do not know a little about the battle of those nineteenth-century giants Adam Sedgwick and Roderick Murchison. What had begun in friendly collaboration gradually developed over a quarter of a century into a bitter feud resulting in mutual estrangement. Like many stories known only in outline, however, the Cambrian–Silurian controversy is surrounded by misconceptions or is not properly appreciated for its most essential characteristic: it was a debate about the proper way to conduct a particular type of science, rather than a mere territorial or priority dispute. With an abundance of letters, notebooks and accounts of meetings available for study, the subject has long been ripe for the sort of book that Secord has written, a detailed, scholarly analysis using modern insights into the sociology of Victorian science.

Through the application of the novel technique of correlating strata by fossils, by the early 1830s great strides had been made in establishing both a relative timescale and producing a reliable geological map for the structurally uncomplicated younger rocks in Britain. The ancient "grauwacke" or transition rocks of Wales, however, were a geological *terra incognita* that provided a kind of new frontier challenge. Sedgwick started work in North Wales and Murchison in the Welsh Borders, which led respectively to their proposing the Cambrian and Silurian systems, with a mutually agreed boundary being established. After some years it became apparent that Sedgwick's Upper Cambrian corresponded with Murchison's Lower Silurian. The newly created Geological Survey adopted Murchison's classification and Sedgwick became increasingly isolated. But the turning point came with the recognition of a major unconformity between Murchison's Lower and Upper Silurian, and the discovery of "primordial" fossils at a stratigraphic level well below that in which anything had previously been found. In the 1850s and 1860s many leading geologists switched their allegiance to a three-fold classification of what we now call the Lower Palaeozoic, and the dispute effectively came to an end in 1879 when Charles Lapworth proposed the term Ordovician for Murchison's Lower Silurian.

Secord argues that "Cambria" and

"Siluria" were conceived of and valued as labels for scientific properties and signals of accomplishment in the quest for originality, with Sedgwick fighting for the Cambrian as a compensation for his failure to complete a major geological book and the more urbane but autocratic Murchison exhibiting a kind of imperialist expansionism in spreading the Silurian both across the world and down to the base of the oldest recognizable fossil-bearing rocks. Whereas Murchison laid emphasis on fossils as the only sound basis for correlation, Sedgwick thought it imperative to establish rock sections with a variety of physical criteria in a way that exemplified the principles of induction that he taught his students at Cambridge; the vehement defence of his Cambrian territory was a kind of moral crusade for the principles of truth and justice as he saw them.

Throughout the dispute, we perceive a characteristic Victorian preoccupation with facts and their classification, rather than with the testing of theories involving process and time. Secord brings out clearly the influence of various social factors in affecting the position which particular people adopted, such as personal competition, the character of the institution to which they belonged, the opportunities for professional advancement and so on. Furthermore, the nature of the underlying assumptions, and indeed the whole conceptual framework, had an influence on what were recognized as "objective" facts.

Secord adopts a straightforward narrative approach and has produced a well-written, sometimes absorbing account which demonstrates convincingly the heuristic value of controversy in promoting scientific advance. What I missed, however, was more of the authentic voice of the leading disputants. Sedgwick was by all accounts a lively and engaging, if somewhat choleric, person who expressed himself with great force and eloquence. It would have been gratifying to see more evidence of this through the inclusion of extended extracts from his correspondence and notebooks, and to contrast it with the more restrained but dogmatic tone of Murchison who is likewise poorly served by quotation. □

John C. Marshall

The Harvard Guide to Influential Books: 113 Eminent Harvard Professors Discuss The Books That Have Shaped Their Thinking. Edited by C. Maury Devine, Claudia M. Dissel and Kim D. Parrish. *Harper & Row:1986. Pp.300. Hbk $18.95; pbk $7.95.*

WHAT do *Rats, Lice, and History, Dynamic Administration, Amateur Telescope Making* and the *Adventures of Pinocchio* have in common? The answer is that each was chosen by *one* of "113 eminent Harvard professors", who here "discuss the books that have shaped their thinking". I emphasize "one" because the most striking characteristic of *The Harvard Guide to Influential Books* is how few choices the contributors hold in common. Between them, the distinguished professors refer to some 560 works, most of which I (and you) have not read. I accordingly thought that the best way to educate myself would be to pick out the *really* influential books, say those that at least five contributors mention. We are now left with *The King James Bible* (seven listings), *War and Peace* (six) and *The Republic, The Federalist Papers* and *The Adventures of Huckleberry Finn* (five each). If authors with listings for multiple books are counted, Winston Churchill, Sigmund Freud, Thomas Mann, William Shakespeare and Max Weber just manage to creep in.

To catch a scientist we must drop to four citations for *On the Origin of Species*. Physicists and chemists are conspicuous mainly by their absence. No one seems to have been much impressed by Galileo, Newton or Max Planck, nor inspired by Lavoisier, Dalton or Mendeleev. Gone are the days when eminent Harvard mathematician Tom Lehrer concluded his song of the elements with the immortal lines: "These are the only ones of which the news has come to Harvard. There may be many others but they haven't been discarvard". Einstein is cited once, by Nicolaas Bloembergen, for his 1938 book (with Infeld) *Physik als Abenteuer der Erkenntnis*. Other physicists enter either as philosophers of science or as (proto-) molecular biologists. (No prizes for guessing Schrödinger's *What is Life?* in the latter category.) Mathematicians figure only as statisticians and "decision theorists" (*vide* Von Neumann and Morgenstern's *Theory of Games and Economic Behavior*). No one's life was made more (or less) uncertain by Heisenberg's principle; no one was converted to existentialism by Gödel's theorem.

In part, the obvious omissions result from the editors' admonition that contributors should not merely recite "Western Civilization's Great Books", but rather tell of the printed matter that *actually* influenced them. Much of the compilation's charm arises from this constraint. Thus architect Moshe Safdie engagingly praises Rudofsky's *Architecture without Architects;* E.O. Wilson confesses that, at age sixteen, Lysenko's *Heredity and Its Variability* enchanted him with its "radical and effective challenge to conventional science"; and, best of all, Mary Chatfield cites "any good cookbook" as evidence that "the rational is still achievable in the most chaotic of worlds". Occasionally one is perplexed by the reasons given for a particular choice. Historian Bernard Bailyn admires Ernest Jones's *Life and Work of Sigmund Freud* as "a morality tale of... heroic achievements", but spoils the effect by concluding "And it happens to be true". For psychologist Richard Herrenstein, *The Trial* and *The Castle* "captured the lunacy and futility of individuals struggling with bureaucracies". Poor Frank: when will people learn that Kafka is not kafkaesque?

None of the faculty has been shaped by the *Talmud*, the *Life of the Buddha* or the *Koran;* indeed, insofar as the "East" (either near or far) exists at all for the contributors it is usually in the form of economic competition with Japan (*vide*, for example, *Japan as Number One: Lessons for America*). Piety comes in predominantly paternal form, although Diana Eck (a professor of comparative religion) writes thoughtfully about Mary Daly's *Beyond God the Father: Toward a Philosophy of Women's Liberation*, and Sidney Verba (director of the University Library) recommends Chaim Grade's memoirs of the *shtetl* in *Rabbis and Wives*. Philosophy tends to the conservative; when Aristotle, Hayek, Hegel, Mill and Popper turn up it is more for their politics than their metaphysics. The spirit of the Law School, the Business School and the Kennedy School of Government dominates the enterprise. *Das Kapital* receives a derisory two votes, *The General Theory of Employment, Interest, and Money* scores zero. Proudhon, Bakunin and Prince Kropotkin fail to make the grade, whilst *Explaining the Cuban Missile Crisis, America's Competitive Edge* and Machiavelli's *Prince* get straight A's. Balance is only marginally restored by educationalist Francis Keppel, who cites *The New York Times*, a choice that serves to remind us that Britain has not had a decent daily since the *Manchester Guardian* dropped the *Manchester*.

Reviewers often decline to take compilations such as this seriously. *Au contraire*, I found the *Harvard Guide* fascinating and deeply informative. My only regret is that space was not found for the book-lists of eminent Harvard secretaries — the people who really keep an institution moving. I eagerly anticipate a series of such volumes from major universities. They would provide a far better guide to advising one's children on which centres of higher learning to apply to than do the usual bland prospectuses. □

Daniel by himself

Jacquetta Hawkes

Some Small Harvest: The Memoirs of Glyn Daniel. *Thames & Hudson:1986. Pp.448. £12.95.*

GLYN Daniel, with characteristic sangfroid, has chosen the tile of *Some Small Harvest* for one of the bulkiest autobiographies of recent times: 448 pages and over 50 illustrations. The first photograph shows a captivating little boy with bright, enquiring eyes, perhaps capable of impudence, and stoutly booted for the successful passage through worldly life that is to be chronicled in such loving detail.

Here I must declare an interest. Glyn Daniel went up to St John's College, Cambridge, during that dawn of modern archaeology, the early 1930s, in the very year that I had graduated. He came from a small village in South Wales, I from a home within half a mile of St John's. We both read for the new archaeological tripos and were to pursue the subject, he with infinitely greater diligence, for the rest of our lives. So it is that I share his memories of very many of the individuals and the events great and small which fill his book. It is hard for me to judge whether others, who must read without the glow of nostalgia, will find it as appealing as I do.

Glyn Daniel not only has an extraordinarily retentive memory but through 40 years has kept a journal which arms him with a record that is "contemporary and explicit". What is striking about the resulting life story is its range and variety. It is an exceptional man who, emerging from an unworldly yeoman background, could become a Wing Commander in India (as head of Central Photographic Interpretation), a brilliantly successful editor of *Antiquity* and of a long series of books of the best *haute vulgarisation*, an adventurous Steward of St John's, a writer on food and drink and of detective fiction — and then, when many felt that all this might have weakened his scholarly repute, carry off the much-honoured Disney Professorship of Archaeology at Cambridge.

Daniel writes of these achievements, interspersed with amusing episodes and anecdotes, as though he took life easy as the grass grows on the weirs, whereas in reality there was within him an iron determination to succeed and a rare capacity for hard work. He has such an enthusiastic interest in his own doings that he perhaps sometimes falls into triviality and self-indulgence; there are, for instance, too many recipes and wine lists, and accounts of lectures and broadcasts — yet for much of the way he carries one along on a tide of his own enjoyment.

For readers of *Nature*, most attention should go to Daniel's archaeological researches and judgements over half a century. Here there is some disappointment. He has published several histories of the subject and can be excused from all such generalities. Yet it would, I think, have given more unity to the autobiography if he could have interwoven the development of archaeological knowledge, method and thought with his personal story; in particular, if he could have gone more fully into the new radiocarbon dating which appears to have nullified much of his extensive research into megalithic monuments, and also examined the present anti-diffusionist fashion. For fashion I believe it to be: how many publications have I read of late where the author is plainly forcing his conclusions into the "local development" mould. It should be added, however, that Glyn Daniel is consistently opposed to what he chooses to call "bullshit" archaeology, the outpourings of those who are honestly deluded or who deliberately indulge in wild fantasies in order to sell their books by the million.

From *Some Small Harvest*

Glyn Daniel, aged five — "stoutly booted for the successful passage through worldly life".

Standing back to judge *Some Small Harvest* as dispassionately as I can, I am convinced that in the long run it will remain valuable as a sociological source-book, a record of Cambridge and especially college life, of travel and conditions in many lands, of the flavour of twentieth-century archaeology — and a highly personal *Who's Who* of scores of the notable characters the author has known. Viewed in this light the very trivia I have criticized will be of unique interest for a future generation, and may be more than forgiven.

Jacquetta Hawkes, Littlecote, Leysbourne, Chipping Camden, Gloucestershire, GL55 6HL, UK, is an archaeologist and author of, among other books, Mortimer Wheeler: Adventurer in Archaeology *(Weidenfeld & Nicholson, 1982).*

NEW BOOKS FROM TAYLOR & FRANCIS

METABOLISM AND ACTION OF ANTI-CANCER DRUGS

Edited by: **G Powis**, and **R A Prough**

This book provides a survey, by a number of experts, of the metabolic processes of the major classes of currently known anti-cancer drugs.

0 85066 369 5 Hard 300pp
Published: 1987 £30/$60

CANCER CAUSES AND PREVENTION

Swedish Cancer Committee

This book is the result of a report commissioned by the Swedish Government in 1979, to examine the incidence of all forms of cancer and its correlation with possible causative factors. It comments on aspects of cancer diagnosis and treatment and on possible social, political, legal, and environmental measures that could reduce the incidence.

0 85066 344 5 Hard 500pp
Published: 1987 £45/$90

PROGRESS IN DRUG METABOLISM

Volume 10

Edited by: **J W Bridges, L F Chasseaud,** and **G G Gibson**

This is an established series containing up-to-date critical reviews of topics concerning the biological fate of drugs and other xenobiotics.

0 85066 372 5 Hard 300pp
Published: 1987 £35/$77

PESTICIDE EFFECTS ON SOIL MICROFLORA

Edited by: **L Somerville, M P Greaves** and **K Domsch**

Pesticides aimed at specific pests on crops end up to a large extent on the ground and, being toxic, can have significant effects on the microflora. This book contains the papers submitted to a workshop on this subject held in 1985.

0 85066 365 2 Hard 250pp
Published: 1986 £30/$60

CHEMICALS FOR ANIMAL HEALTH CONTROL

George C Brander

The aim of this book is to discuss the impact of new methods of disease control in animals and to consider many of the new fields of therapy which have become important to the farmer.

0 85066 311 3 Soft £12.50/$25
0 85066 358 X Hard £25/$50
Published: 1986 220pp

CONTROL OF MAMMAL PESTS

Edited by: **C G J Richards** and **T Y Ku**

This book deals with control, mainly with poisons, of mammal pests, especially rodents, and the methods and strategies for countering these pests.

0 85066 371 7 Hard 250pp
Published: 1986 £39/$80

CLINICAL PHARMACOLOGY OF ANTI-INFLAMMATORY AGENTS

P M Brooks, W F Kean and **W W Buchanan**

This volume provides a concise review of the process of inflammation, giving an integrated understanding of the pharmacology of analgesics, non-steroidal anti-inflammatory drugs, the non-specific anti-rheumatic drugs and the clinical treatment of inflammatory rheumatic diseases.

0 85066 331 8 Hard 160pp
Published: 1986 £16/$45

DRUGS AND DRIVING

Edited by: **J J de Gier** and **J F O'Hanlon**

The effects of drugs on drivers' performance are coming under increasing scrutiny, as they could be the cause of road accidents. Pressures are mounting for tests to be introduced in the pre-marketing examination of new medicinal drugs. This book is the result of a seminar held in 1984 to look into all aspects of this important subject.

Books from SCIENCE

The Journal of the American Association of the Advancement of Science

Aids

Papers from *Science*, 1982-1985

Edited by Ruth Kulstad

Some of the most frequently cited papers on acquired immune deficiency syndrome (AIDS) that appeared in *Science* between August 1982 and September 1985 are brought together in this unique source book on AIDS. The collection is particularly timely both because of the experimental data included and because the papers provide an excellent source for references to related work in other journals. Arranged chronologically, the 108 research papers and *Science* news reports show how far AIDS research has come, providing a brief history of the AIDS epidemic through September 1985. The research papers indicate the state-of-the-art techniques applied to studies of the AIDS virus and set out probable directions for future research. The news stories focus on some of the problems associated with investigating a disease occurring predominantly — at least in the US — with homosexual men, on the early reluctance of the government to provide adequate research funds, and on the problems that may be encountered in caring for large numbers of sick and dying patients.

An overview of AIDS research to date is given in the introduction by Dr Myron Essex, chairman of the Department of Cancer Biology, Harvard University School of Public Health.

Ruth Kulstad is a senior editor with *Science*.

1986-653 pages w/notes, tables, figures, biblio, indexes.
ISBN 0-87168-313-X (hc). £24.00.

Astronomy and Astrophysics

Edited by Morton S. Roberts

The fields of astronomy and astrophysics have exploded in recent years in the wake of technological and theoretical advances. This volume, a survey of the solar system, the structure and content of the galaxy, galaxies and cosmology , and instrumentation, is an attempt to assess the current state of knowledge of astronomy. The editor of this collection has organized 24 articles, including two Nobel Prize Lectures, originally published in *Science* between 1982 and 1984, on topics ranging from the solar system to the pulsars at the very edge of the observable universe. Each article is self-contained, yet as a whole, the volume reveals a broad, coherent, and contemporary picture of our astronomical universe. Selected for their depth of coverage and breadth of topics, these articles are of interest to the entire scientific community.

Morton S. Roberts is director of the National Radio Astronomy Observatory.

Contents (partial): Introduction. Solar System. Structure and Content of the Galaxy. Galaxies and Cosmology. Instrumentation.

1985; 383 pages w/colour plates, index.
ISBN 0-87168-311-3 (hc). £24.00

Biotechnology

The Renewable Frontier

Edited by Daniel E. Koshland, Jr

Like its 1984 predecessor, *Biotechnology and Biological Frontiers*, this new volume covers the latest and most important topics in biological research and development. The collection includes papers that appeared in *Science* after November 1983 and provides an update on state-of-the-art techniques in both fundamental and applied biotechnology.

Daniel E. Koshland, Jr, is the editor of *Science*.

July 1986; 400 pages w/tables, figures, biblio, index.
ISBN 0-87168-314-7 (hc). £24.00

Biotechnology and Biological Frontiers

Edited by Philip H. Abelson

Covering the most important topics at the forefront of biological research and development, this book addresses both fundamental research techniques and practical applications. Part 1, biotechnology, is devoted to a broad sampling of the current revolution in applied biology. Recombinant DNA and hybridomas, protein engineering, tissue culture of plants, and industrial fermentations are among the topics discussed. The emphasis in Part II, biological frontiers, is on basic research at a time when the enormous power of experimental techniques is producing answers to long-standing biological questions. Consisting of 36 outstanding papers from *Science* by 136 scientists representing industrial, university, and governmental laboratories and institutes worldwide, this volume will be of interest to researchers and students in all fields of biology, agriculture, and the health sciences.

Philip H. Abelson is the former editor and current deputy editor for engineering and applied sciences at *Science*.

1984; 550 pages w/colour plates, index.
ISBN 0-87168-308-3 (hc). £24.00

Frontiers in the Chemical Sciences

Selected and with an Introduction by William Spindel and Robert H. Simon

There has been an explosion in the field of chemistry within the last ten years resulting from powerful new research techniques and an expanding of areas of study. Many new tools and capabilities are being developed throughout the full range of analytical, physical, organic, biological, and materials chemistry. This volume details progress in these areas, including new work on ultrafast reaction dynamics, surfaces and catalysis, organometallics and conduction organics, enzyme mechanisms and other life processes, stereoselectivity and asymmetric syntheses, and catalysis.

William Spindel and Robert M. Simon are members of the National Research Council Board on Chemical Sciences and Technology.

October 1986; 400 pages w/tables, figures, notes, biblio, index.
ISBN 0-87168-312-1 (hc). £24.00

Neuroscience

Edited by Philip H. Abelson, Eleanore Butz, and Solomon H. Snyder

Discoveries made during the recent renaissance in neuroscience research in areas ranging from genetic engineering to clinical therapy are presented in this collection. Within its four sections — neuroplasticity, molecular biology, synaptic transmission, and behaviour — the volume provides an integrative treatment of brain anatomy, physiology, and chemistry and addresses fundamental questions concerning nervous system functioning. The editors have pulled together 27 seminal papers from *Science* representing the work of 84 researchers at private and federal laboratories and hospitals, integrating the disparate disciplines in neuroscience.

Philip H. Abelson is the former editor and current deputy editor for engineering and applied sciences at *Science*, Eleanore Butz is senior editor with *Science*. Solomon H. Snyder is director of the Department of Neuroscience and distinguished service professor of neuroscience, pharmacology, and psychiatry at The Johns Hopkins University School of Medicine.

Contents (partial): Introduction. Neuroplasticity. Molecular Biology. Synaptic Transmission. Behaviour.

1985; 460 pages w/colour plates, index.
ISBN 0-87168-309-1 (hc). £24.00.

Butterworths Biotechnology Series

Mammalian Cell Technology

William G Thilly, Department of Applied Biological Sciences, MIT, Massachusetts, USA

This new book presents an organised review of the essential elements necessary in the attempts to use fermentors instead of animals to grow animal cells and to produce physiologically active macromolecules. The underlying principle of the book is that mammalian cell fermentor productivity is the product of single cell productivity and the number of cells achieved in a fermentor. The contributors have presented an orderly overview of the important aspects of the genetics, physiology and growth of animal cells.

Hardcover 192 pages October 1986 £48

Overproduction of Microbial Metabolites

Z Vanek and Z Hostalek, both of the Czechoslovakian Academy of Sciences, Prague, Czechoslovakia

Overproduction of microbial metabolites is a complex process which can be achieved by using knowledge of control mechanisms on the genetic and metabolic levels. This volume presents an in-depth look at the various strategies used in industry to obtain preferential expression of desired metabolic pathways.

Hardcover 316 pages October 1986 £59

WHERE WILL IVF LEAD US?

In Vitro Fertilisation

past, present and future

Edited by S Fishel, *The Park Hospital, Nottingham,* and E M Symonds, *University of Nottingham*

Few topics are subject to such intense argument and so little understood.

This new book prepares you for this compelling debate. The editors have assembled the work of scientists, doctors, sociologists, philosophers, lawyers and politicians to present a comprehensive and international investigation of this fascinating field.

Contents

IVF – past and present • The infertile couple • Follicular growth, ovulation and the use of ovarian stimulants • Endocrine evaluation of the infertile woman • Ultrasound for oocyte recovery • Laparoscopy for oocyte recovery • Preparation for IVF in the laboratory • Andrology and semen preparation and preservation for IVF • Growth of the human *conceptus in vitro* • Computing in IVF • Replacement of the embryo • Pregnancies, abortion and birth after IVF • Variations in current IVF programmes – in-patient versus out-patient treatment • Caring for the IVF patient – nursing care • Caring for the IVF patient – counselling • The ethical debate • The legal situation • The current status of the Warnock Report and other international reports • The political debate • Test-tube babies – the child, the family and society • IVF – the future

ESTROGEN/ANTIESTROGEN ACTION AND BREAST CANCER THERAPY

V. Craig Jordan, editor

This volume, which brings together the leading scientific minds in the field of breast cancer research, traces the development of the understanding of estrogen action and its application to breast cancer therapy. The contributors, who include many of the principal scientists and clinicians involved in this period of research and discovery, trace the discovery of antiestrogens and their successful use as a nontoxic therapy for breast cancer. These papers will be of significant interest and value to students, scholars, and researchers in oncology, biochemistry, pharmacology, endocrinology, and cell biology.

The main goal of this book is to allow the planning of strategies for the application of research for the successful treatment of breast cancer with antiestrogen drugs.

NEW AUTUMN BOOKS FROM ELSEVIER

WORLD SURVEY OF CLIMATOLOGY, 1B

General Climatology, 1B

Elements of Statistical Analysis

by **O.M. Essenwanger**

With the development of electronic data processing, the field of statistical analysis has mushroomed. The availability of a vast amount of software allows the meteorologist to use statistics as a tool to a high degree and sophisticated statistical analysis of meteorological data is now possible. The author has selected a number of topics comprising a mixture of familiar and modern subjects of statistical analysis which will introduce the reader to climatological data processing.

Biogeochemical Processes at the Land-Sea Boundary

edited by **P. Lasserre,** *Paris, France and* **J.-M. Martin,** *Paris, France*
(Elsevier Oceanography Series, 43)

There is an intuitive belief among scientists that each estuary or lagoon is unique and different. Similarities do exist, however, and this book attempts to highlight some common properties and perhaps some innovative views on biogeochemical processes, and biological fluxes which are of central concern in the understanding of the land-sea boundary.

ISBN 0-444-42675-2

Handbook of Environmental Isotope Geochemistry

edited by **P. Fritz,** *Ontario, Canada, and* **J.Ch. Fontes,** *Orsay, France*

The *Handbook of Environmental Isotope Geochemistry* comprises a series of books, each focussing on a selected environment, presenting in-depth reviews of all relevant studies and results obtained in specific research areas. The first volume, Part A, was described by one reviewer as "*everything we wanted to know about isotopes and much, much more... without doubt, a necessary reference book for any geochemist*". The second volume continues the coverage of terrestrial environment, and contains an equally impressive and authoritative collection of papers.

The Origin of Arcs

edited by **F.-C. Wezel,** *Urbino, Italy*
(Developments in Geotectonics, 21)

A collection of papers presented as distinguished guest lectures at the International Conference on "The Origin of Arcs" held at the University of Urbino on 22nd-25th September 1986, under the joint sponsorship of the European Union of Geosciences and the Italian Geological Society.

1986 xx + 568 pages; US$ 80.00 / Dfl. 180.00;
ISBN 0-444-42688-4

Terminal Eocene Events

edited by **Ch. Pomerol,** *Paris, France, and* **I. Premoli-Silva,** *Milan, Italy*
(Developments in Palaeontology and Stratigraphy, 9)

The papers in this volume provide an exhaustive inventory and description of the most complete sedimentary sequences across the Eocene-Oligocene Boundary (EOB) from all over the world, and present a synthesis of the biotic and chemico-physical events detected at the Eocene-Oligocene transition.

1986 xii + 414 pages; US$ 69.00 / Dfl. 155.00;
ISBN 0-444-42623-X

Occupied territory

Randall White

The Palaeolithic Settlement of Europe. By Clive Gamble. *Cambridge University Press:1986. Pp. 469. Hbk £40, $65; pbk £15, $24.95.*

ACCORDING to current evidence, Europe was first occupied by hominids 1.5 million years after the first Palaeolithic toolmakers emerged in Africa. There is much that remains to be known about this successful expansion of our species into northern latitudes, but there is also much information presently available. Research on the Palaeolithic settlement of Europe (roughly 750,000 – 12,000 years ago) is published in so many languages, and is based upon such a variety of theories, that it is difficult for any scholar to have a clear overall view of the subject. Clive Gamble's drawing together of knowledge and references from such an intellectual mosaic is in itself a great achievement.

It must be said, however, that the framework on which the book is organized is puzzling, if not idiosyncratic. The first chapter, which begins with a history of European Palaeolithic studies, concludes with a strong advocacy of Binfordian methodological premises. While Binford has had a very positive influence on European Palaeolithic studies, it is a little surprising to find his views uncritically repeated virtually word for word.

The following chapter, "Hunter–Gatherer Regional Systems", takes a detailed look at regional and inter-regional adaptations among contemporary hunter–gatherers. At the end of it, Gamble follows Robert Foley in proposing rejection of the site as an analytical unit for the study of prehistoric hunter–gatherers. This has become a popular position recently; but it deserves much closer scrutiny in light of the fact that sites do correspond to palimpsests of past living *communities*, a concept critical to regional studies of living peoples. I found this chapter especially troublesome in its heavy emphasis on 1960s ecological thinking. The result is a form of ecological functionalism which views the social world of hunter–gatherers exclusively with reference to the imputed functions of "alliance" and "information strategies". Anthropological theory in the 1980s is not what it was in the 1960s, and for Gamble to cite Marshal Sahlins's ideas of 1968, without acknowledging Sahlins's refutation of the ecological paradigm, betrays an unduly selective approach.

Chapter 3 is a complex presentation of data on environments and resources. Gamble breaks Europe down into nine sub-regions, upon which are based the inter-regional comparisons in the rest of the book. Discussion of glacial chronology is detailed and excellent. Also here is a listing of the key anatomical and behavioural attributes of the main faunal species, which is very helpful but unfortunately omits certain attributes of importance to human beings, such as hide and antler quality and aggregation behaviour.

In the next, very short chapter, entitled "Technological and Typological Approaches", Gamble explores technological and typological evolution during the European Palaeolithic. The result is a severe revision of the traditional sequence in which the present Middle and Lower Palaeolithic are melded to form the "Early Palaeolithic", which comprises all industries before 35,000 years ago. The terms Lower and Middle Palaeolithic are inadequate, and Gamble's lumping of the periods together clears the decks for future analyses of much potentially interesting variation. It is all the more curious, then, to see him become a splitter when he turns his attention to the Upper Palaeolithic, creating two divisions (before and after 20,000 years BP). The later division is based upon the emerging importance of microliths after 20,000 years BP. Unfortunately, it ignores recent excavations in which Aurignacian (caminade scrapers) and Gravettian (microgravettes, backed bladelets) levels have yielded abundant microliths.

Chapter 5 is a useful, well-referenced discussion of the data base for research on Palaeolithic Europe, organized according to Gamble's newly developed temporal and geographical structure. Each region is summarized according to (1) chronology, (2) industrial groupings, (3) geographical variation and regional case-studies, and (4) burials and art (though the last of these is rather sketchy).

The sixth chapter, "Space and Subsistence", is the best in the book and probably the most comprehensive account of Palaeolithic settlement and subsistence patterns that has appeared to date. There are two shortcomings, however. First, because of its supposed circularity site-location research is summarily dismissed. Second, after having illustrated some brilliant work on intra-site spatial patterns, Gamble re-states his view that the site should not be our focus of analysis. My position is that the examination of individual sites must be used to build a regional picture of human landscape use.

"Demography and Style", the next chapter, is puzzling, because the section on demography deals almost exclusively with carnivore behaviour as a basis for research into the distribution of populations in space. The section on style and interaction relies heavily on information approaches to variability in material culture, exemplified by Gamble's own work on Gravettian female figurines. Again, in true 1960s fashion adaptive significance is attributed to form in portable and cave art; based upon a very narrow reading of the Australian literature, the latter is treated as territorial marking rather than as evidence for complex systems of meaning that help to define the very nature of human adaptation.

Chapter 8, "Society, Sediments and Settlement", emphasizes the interesting regional differences in stone-tool and site densities. Here, Gamble wishes to chip away at the notion that a universal set of Upper Palaeolithic traits, rather than local environmental exigencies, conditioned the archaeological record in all regions. This is indeed an important issue, but Gamble's density calculations need to be examined closely before being accepted. For example, his find-spot density for the Perigord is based on a surface area of 12,600 square kilometres, approximately twice the true figure. Moreover, historical differences in the intensity of site search need to be taken into consideration. It is a pity that Gamble fails to suggest the need for systematic controlled survey to control sample quality in assessing overall population increase across the transition between the Middle and Upper Palaeolithic.

In the concluding chapter, the virtues of viewing culture as an adaptive process are extolled, especially as applied to the emergence and diversification of culturally modern humans at about 35,000 years BP. Gamble seems not to recognize that those of us who view the Upper Palaeolithic as an evolutionary threshold are not anti-adaptive; rather, we are comfortable in switching back and forth between discussion of the evolution of culture and the evolution of cultures.

More disturbing in the conclusion, however, are the peculiarities that emerge in the form of three models for what human beings did when they reached Europe. The problem posed by cold northern climates is viewed primarily as a problem of finding a niche, which ignores clothing, fire and shelter as cultural evolutionary prerequisites. In any event, Gamble proceeds to propose that the earliest Europeans were adapted to the consumption of frozen animal carcasses resulting from natural deaths in autumn and winter. He seriously suggests that the wooden "spears" from Lehringen and Clacton were probes for finding dead animals beneath the snow. This is an unfortunate excursion onto the fringe.

While readers must work around some awkward theoretical and organizational impediments, the rich (though already somewhat dated) documentation and first-class presentation of this book will make it a basic reference in English-language Palaeolithic studies for years to come. ☐

Principled man in unprincipled times

Martin J. Klein

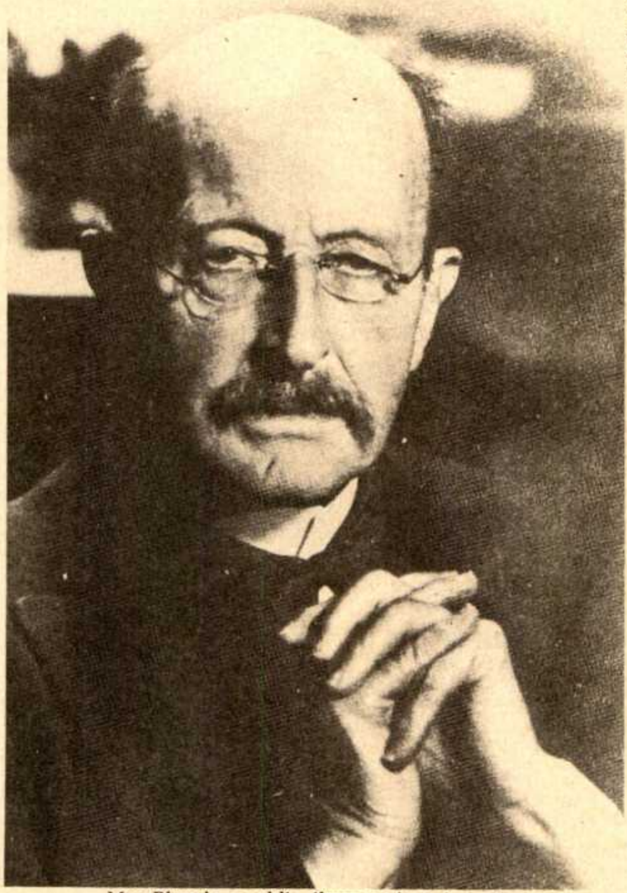
The Dilemmas of an Upright Man: Max Planck as Spokesman for German Science. By John L. Heilbron. *University of California Press: 1986. Pp.238. $16.95, £14.50.*

MAX PLANCK (1858–1947) exemplified the traditional values of the world in which he grew up, the world of a conservative, cultured German family of pastors, scholars and jurists. The very model of a classical physicist, he "embodied with rare completeness", according to Albert Einstein, the "ideal search for truth . . . a bond forever uniting scientists of all times and in all places". But his very devotion to the search for absolute scientific truth led Planck inexorably to the quantum of energy with which his name is permanently linked, the symbol of this century's nonclassical physics. His unshakable sense of responsibility led him, equally inexorably, to accept a series of positions of authority in the German academic and scientific establishments. By 1914 he had become the acknowledged spokesman for German physics, a role he could not in conscience relinquish when his country was transformed into the Weimar republic and then entered the dark times that began in 1933. As John Heilbron writes in his preface, Planck's

> struggle to come to grips with changing political circumstances, and his efforts to adjust the image of science and civic life that he developed before 1900 to the realities of twentieth-century Germany have the elements of heroic tragedy.

Heilbron's book, the first in English devoted to Planck, is an outstanding piece of work by one of our finest historians of science. Heilbron's earlier writings include an admirable study of Henry Moseley's life and work, a major book on early intellectual and institutional developments in physics, *Electricity in the 17th and 18th Centuries*, and a series of articles and monographs on a wide range of subjects in the physical science of the past four centuries. Among its other impressive features, his work always shows his mastery of "the bibliographic resourcefulness proper to the historian".

As his title implies, Heilbron's primary concern in this book is Planck's role as spokesman for science rather than the physics he actually did. Heilbron does sketch Planck's development from exclusive devotee of thermodynamics through his gradual acceptance of the need for both atomism and a statistical approach, and he shows how Planck used his hard-won theory of blackbody radiation to determine the first reliable values of the atomic constants. We see Planck, conservative in his stance towards the developing quantum theory, immediately and enthusiastically respond to the special theory of relativity and its author. Planck was one of those who brought Einstein to Berlin in 1914, and it was Planck's presence that helped to keep him there: "To be near Planck is a joy", Einstein once wrote.



Max Planck — public silence, private integrity.

Mary Evans

There is no irony in Heilbron's designation of Planck as an upright man. "Respect for laws, trust in established institutions, observance of duty, and absolute honesty" are listed as "the hallmarks of Planck's character". These were combined with genuine modesty and the clear conscience that came with his responsible adherence to his principles. Not a man for public pronouncements, Planck showed his opposition to academic anti-Semitism preceding the First World War by acting quietly to keep qualified Jewish physicists such as Emil Warburg and Lise Meitner from being denied positions on irrelevant grounds.

By 1914 Planck held a series of major positions in the German Physical Society, the Prussian Academy of Sciences, the Kaiser-Wilhelm-Gesellschaft, and, as war began, as Rector of the University of Berlin. He faced the war with mixed emotions, foreseeing "something great, along with something monstrous". Planck was one of the 93 intellectuals who signed the famous "Appeal to the Cultured Peoples of the World" in October 1914, denying German atrocities in Belgium and expressing the unity of German culture and German arms. Unlike most of his cosigners he soon moderated his position and worked to maintain the possibility of post-war international reconciliation among scientists. His 1916 open letter to H.A. Lorentz emphasized his

> firm conviction that there are domains of intellectual and moral life that lie beyond the struggles of nations, and that honourable cooperation in the cultivation of these international cultural values and, not less, personal respect for citizens of enemy states are indeed compatible with ardent love and energetic work for one's own country.

Few citizens of any belligerent nation have publicly subscribed to such enlightened views in the midst of a modern war.

Planck had to call on all his internal resources to go on with his work after his own losses in the war years: his first son was killed in action and his twin daughters both died in childbirth. Devotion to duty sustained him in this time of personal grief and national upheaval. Unlike many of his conservative colleagues he gave his loyal support to a republic whose principles were not his own. Heilbron discusses Planck's staunch support of Einstein when vicious anti-Semitic attacks were directed against both the man and his general relativity, but he stresses Planck's avoidance of public statements that he thought might encourage the politicization of science. We see Planck struggling to help restore normal international relations among scientists despite the severe restrictions imposed by the victorious Allied powers. As if these tasks and his efforts to secure adequate financial support for physicists were not enough for a man approaching his seventieth year, Planck also undertook to defend a causal, realistic philosophy of physics in the new age of quantum mechanics.

The problems Planck dealt with in the Weimar era were minor compared to those he confronted after Hitler took power in 1933. As secretary of the Academy and president of the Kaiser-Wilhelm-Gesellschaft, Planck could not avoid dealing with the government. Convinced at first that the Nazi excesses could not last, and that Hitler's call for national revival and unity had much to be said in its favour, Planck was ready to accommodate to the demands of the new regime. At 75 he would have been relieved to give up the burdens of his offices, but he felt responsible to those who counted on his help and trusted his "immensely noble purity".

Planck's hopes for quick return to civilized behaviour in Germany were quickly dashed when his Jewish colleagues were forced out of their positions and many of them left the country. Still reluctant to make public statements, Planck did not protest against the Academy's offensive response to Einstein's resignation. He went on advising his younger colleagues to have patience and stay at their posts. Nevertheless, it was Planck who went directly to Hitler in May 1933 and tried to convince him that his policies were destroying German science. Hitler would make no distinctions, and became so enraged that Planck could only "fall silent and take my leave". His efforts to salvage what could be salvaged, to block (behind the scenes) the irrational behaviour of his fellow Nobel laureates Philipp Lenard and Johannes Stark, both enthusiastic admirers of Hitler since 1924, did have some positive results. More and more frequently, however, he had to compromise his principles and accept the unacceptable.

During the Second World War, now an octogenarian but free of offices at last, Planck continued his public lectures on science and philosophy, using them as a platform for defending the values of science and civilization and for implicit criticisms of the regime. The disasters of the war, and especially the arrest and execution of his son Erwin for complicity in the 1944 attempt to assassinate Hitler, finally broke Planck's spirit. He died in 1947, just short of his ninetieth birthday.

Heilbron's thoughtful book makes it clear that there were no easy answers to the dilemmas Planck faced. Einstein did not forgive Planck for his public silence in 1933, but he had never lived with Planck's responsibilities. One can speculate on what might have happened if Planck had made a different series of decisions, but speculation is only speculation. Planck acted in accordance with his principles and his conscience, though the world crumbling around him had little place for either. Heilbron writes in his preface that Planck's "life is a lesson", but each reader must decide for himself what that lesson is. ☐

Martin J. Klein is Higgins Professor of the History of Physics at Yale University, Box 2036, New Haven, Connecticut 06520, USA.

Matter of utmost gravity

Joseph H. Taylor

Was Einstein Right? Putting General Relativity to the Test. By Clifford M. Will. *Basic Books: 1986. Pp.253. $18.95.*

IN THE centenary year of Albert Einstein's birth, 1979, a number of books appeared which described the man and his science, especially general relativity. Seven years later, Clifford Will has added another to the list — a readable volume detailing the renaissance that has taken place in gravitational physics since a few years after Einstein's death in 1955. Writing for a general audience, Will describes (sometimes with first-hand knowledge, and always with flair) developments of the past quarter-century which provide the underpinnings of our understanding of the gravitational interaction in nature and its apparently inextricable connection with the geometry of the Universe.

The 1960s, heyday of radio astronomy, dawn of the space age and beginning of the era of atomic clocks, saw for the first time the development of experimental techniques well suited to the high-precision measurement of tiny differences between the predictions of newtonian gravitation theory, general relativity and other "currently viable alternatives". Will tells us of these developments, taking a topical approach. He starts with the reincarnated "Eötvös experiments" carried out in Princeton and the Soviet Union, which verified the equivalence principle to very high precision. Gravitational red-shift tests are described next, with emphasis on the Pound–Rebka–Snider experiments using gamma rays in the Jefferson Tower at Harvard, and the "flying atomic clocks" experiments carried out by Robert Vessot and others a few years later. Together, these tests showed conclusively that a correct theory of gravity must be a metric theory, embodying the concepts of curved space-time.

Subsequent chapters deal with modern experiments measuring the bending of radio waves by the Sun's gravity, the perihelion shift of Mercury by radar ranging techniques, the slowed propagation of signals in the solar gravitational field, extension of the equivalence principle to include the self-gravitational binding energies of the Earth and Moon, the constancy of the gravitational "constant" G, and the loss of orbital energy in the binary pulsar system by gravitational radiation. Throughout the narrative, Will sprinkles a trail of personalities and anecdotes. Robert Dicke's name appears frequently: first as the author of a 1961 article in *Scientific American* which helped to convert the teenaged Clifford Will from a career in architecture, or maybe genetics, to one in physics; later as quintessential experimenter, and co-author of a theory of gravitation to rival Einstein's; later still as a passenger on an airplane bound for Missoula, Montana, on which he was informed by Kenneth Nordvedt, then a total stranger, that the Brans–Dicke theory appeared to be inconsistent with the equivalence principle for strongly self-gravitating bodies.

Irwin Shapiro's discovery of the gravitational propagation delay for electromagnetic waves makes a good story; it includes an image of Shapiro making an eleventh-hour pitch — via long-distance telephone connection from Cambridge, Massachusetts, to the Jet Propulsion Laboratory in California, complete with locally shown viewgraphs, NASA style — pleading for inclusion of the time-delay experiment on the forthcoming Viking mission to Mars. The story of the discovery of the Hulse–Taylor binary pulsar is here, too, complete with graphical sketches reproduced from Russell Hulse's laboratory notebook and with the correct inference that graduate student Hulse and assistant professor Taylor were thoroughly astonished by the potential implications of what they had found.

Lincoln Laboratory. Reproduced from *Was Einstein Right?*

Radar ranger — the Millstone Hill antenna, northern Massachusetts, used by researchers at the Massachusetts Institute of Technology from 1959 for radar echo observations of the planets.

Will has succeeded in what he set out to do, namely to write an interesting and accessible account of recent progress in one field of physics. ☐

Doctor, doctor...

Nicholas A. Rupke

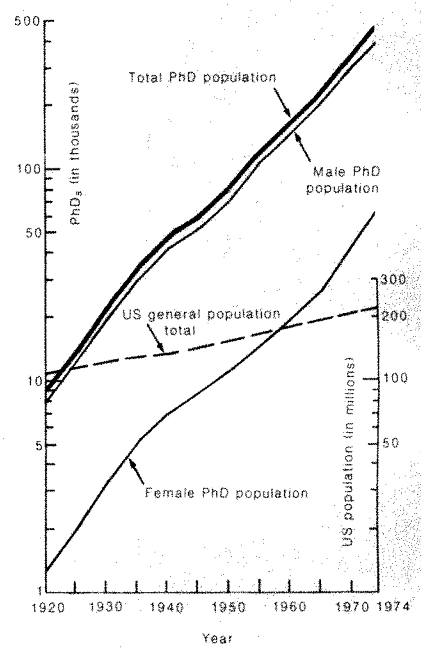
Frontiers of Learning: The Ph.D. Octopus. By Pjotr Hesseling. *Foris Publications:* 1986. Pp. 204. Hbk £27.95, $44; pbk £17.95, $27.*

"CANDIDATES must have a PhD . . .". This stipulation has become a standard phrase in the job advertisement columns of science magazines. The PhD, it would appear, has come to represent something of a passport to academic jobs and a union card for the would-be industrial scientist. Employers routinely use the qualification as a preliminary screening device to whittle down large numbers of applicants, often for jobs in which research training has little relevance. Although a result has been a steep rise in the number of people holding a doctorate, especially in the United States, relatively little is known about the PhD phenomenon. What is the function of the degree, its intrinsic worth, as the crowning feature of higher education? What fruits do we expect it to yield? What precisely should it represent? Is the recent multiplication of doctoral degrees a sign of academic health or a craze that is devaluing them?

It is questions such as these that Pjotr Hesseling, professor of business economics at the Erasmus University of Rotterdam, addresses in this book. He uses a comparative approach, looking at the history of the PhD in different countries and cultures. In its modern form the PhD is a German invention, the foundation of the University of Berlin in 1810 marking the beginning of higher education centred on the research imperative. The doctorate became less of an ornamental initiation rite and more of a serious research accomplishment, representing an independent and original contribution to knowledge, embodied in a book-length dissertation. From Germany the PhD moved to the United States (first award in 1861), Britain (1917) and more recently to Japan (1953), gradually penetrating the higher education system of each country.

In the course of its global advance, the PhD has been adapted to various indigenous cultural traditions. The European doctorate is to some extent still a shibboleth of originality and cultural authority (although the precise appreciation varies between disciplines and countries); the American doctorate is primarily used for pre-career training and as a certificate for entering the academic and other professions; the Asian doctorate, which Hesseling has studied mainly in Indonesia and Japan, is still in a formative phase, being made to fit old traditions of scholarship and wisdom on the one hand, and new, pragmatic considerations of state-managed science policy on the other. Despite these differences, the American graduate school, envied for its productive efficiency, is increasingly becoming the model for the rest of the world.

Hesseling regrets the "Americanization" of the PhD, which is turning it into market-orientated training during which a candidate will often be assigned a narrowly defined topic within a pre-existing research programme. The PhD, he believes, is becoming too much part of government-directed science policy and of university administration preoccupied with production costs. Quality should be what matters most, but this feature is too elusive to be regulated to any great extent. Originality in research, although the outcome will be less certain, should have priority over completion rates — the reverse of what a recent OECD report, *The Role and Function of Universities: Post-graduate Education in the 1980s*, says on the subject.



PhD explosion — the rise in the number of living holders of doctorates earned in the United States between 1920 and 1974.

Redrawn from *Frontiers of Learning*

Hesseling does not believe that the doctoral dissertation is a necessary complement to the education of all postgraduates. To him, the PhD should be part of a special "cultural mission" which includes testing received knowledge, overcoming boundaries between disciplines, institutions and nations, and striving for such ideals as disinterestedness and communalism. A doctorate should explore, as the title of his book states, "The Frontiers of Learning" and not be an overspecialized tentacle of "The Ph.D. Octopus" (a sub-title borrowed from the Harvard psychologist William James).

---

*PO Box 509, 3300 AM Dordrecht, The Netherlands, and PO Box 5904, Providence, Rhode Island 02903, USA.

To achieve this end, Hesseling advocates a European doctorate through the revitalization of the traditional academic peregrination which made use of the advantages of different systems A code of practice should be adopted by the main European universities with, among other things, the abolition of fixed completion periods for doctoral projects, emphasis on interdisciplinary work, freedom for the candidate to select both topic and supervisors (the latter from more than one university), use of external examiners (already the practice in Britain) and publication of the thesis in a major language

One can readily sympathize with these ideals But given the increasingly tight and competitive marketplace, and given also the domination of the American system, the need to hold a doctorate as well as a bachelor's and a master's degree is greater than ever It would therefore seem unrealistic to revert to a system of higher education in which the PhD is for the relatively few Furthermore, Hesseling's ideals are to a large extent accommodated, especially in the Anglo-American world, by the network of post-doctoral fellowships which provide an opportunity to elaborate and publish doctoral theses Many of these fellowships are held in institutes for advanced study with their interdisciplinary and international atmosphere The Princeton Institute has been replicated, *mutatis mutandis,* not only in the United States itself but also in Germany, The Netherlands and Scotland In England, several of the Oxbridge colleges give hospitality to advanced researchers in different disciplines

Closer examination of these and related questions is obviously needed Hesseling's book is seriously flawed stylistically — there are innumerable mistakes of English usage and unnecessary repetitions of material, and many passages are exasperatingly vague But he has brought a commendable breadth of approach to his subject, and has provided much food for thought for anyone interested in higher education □

Nicholas A Rupke, Wolfson College, Oxford, OX2 6UD, UK, is a geologist and historian of science and medicine

Quantum question

Philip Pearle

The Shaky Game: Einstein, Realism, and the Quantum Theory. By Arthur Fine
University of Chicago Press 1986 Pp 179 $25, £21 25

EVEN such a loving biographer of Einstein and his physics as Abraham Pais seems embarrassed by Einstein's position on quantum theory In his book '*Subtle is the Lord*', Pais quotes Einstein — "I feel that the real joke that the eternal inventor of enigmas has presented us with has absolutely not been understood as yet" — and then remarks, "It is believed by nearly all of us that the joke was understood soon after 1925 " Given this belief, and the spectacular successes of quantum theory which nurture it, it is perhaps not surprising that sympathetic and careful analyses of Einstein's attitude have been lacking

This lack is quite satisfactorily addressed in five (the second to sixth) of the nine essays which make up this book The essays, most of which have been previously published, are clear, well-reasoned and appropriate settings for the gems they are studded with, quotes from the Einstein archives at Princeton The sixth essay, "Einstein's Realism", forms a bridge to a rather different piece of country, three provocative articles on realism which reject both it and anti-realism in favour of the author's own position, which he calls the "Natural Ontological Attitude" (NOA)

The second essay, which follows an introductory chapter, attacks the often-promulgated view that Einstein's position on quantum theory represented a "kind of scientific senility" After giving ample evidence that Einstein's way of thinking supported Poincaré's admiring assessment of " the facility with which he adapts himself to new concepts He has not remained attached to classical concepts ", Fine refreshingly concludes that " it was Bohr not Einstein who felt bound by the classical concepts", and "in the end Einstein was more radical in his thinking "

The third essay details Einstein's route to the conviction that quantum theory is not " in principle capable of producing a complete description of an individual physical system", and culminates in a discussion of the famous Einstein–Podolsky–Rosen paper For those of us who have secretly never felt fully at ease with the tortuous arguments in that paper, and who have wondered how that master of clarity, Einstein, could have done this to us, Fine brings welcome relief He shows just how complicated the argument of the paper is, presents evidence that Podolsky wrote it without revision by Einstein and analyses a simpler argument that Einstein sent to Schrodinger in a letter The fifth essay also concerns letters from Einstein which stimulated Schrodinger while he was writing his famous paper on the cat paradox This paper showed that quantum theory can predict a state for a cat that is a superposition of cat-alive plus cat-dead, an unrealistic situation for a single cat, thus supporting Einstein's statistical interpretation of quantum theory " the description not of a single system but of an ensemble of systems" How delightful to learn that Einstein himself initiated this paradox, with an example of unstable gunpowder in a quantum state of unexploded plus exploded[1]

I found essay four on Einstein's statistical interpretation to be rather incomplete Perhaps because Einstein felt that the de Broglie–Bohm "hidden variable" model is not fundamental enough, no discussion is given of this or the models of Wiener–Siegal or Nelson, which many feel are nice examples of how a statistical interpretation may function Instead Fine presents some of his own work, a refutation of a model he calls "The Standard Answer" (a sharper earlier refutation due to Kochen and Specker is not mentioned) and a possibly satisfactory "Prism Model" whose similarity to the so-called "loophole" models and vulnerability to experimental refutation is not mentioned (until the last essay)

Einstein's realism is analysed next, understood as a faith, and dubbed "Motivational Realism" Fine shows that Einstein, while driven by a passionate realism, drew back from making logical assertions connecting physics to that reality Apparently philosophers are not so judiciously reticent, and Fine rebuts both realist and antirealist positions Instead he opts for NOA, a minimalist position, that accepts the truth of what is useful (for example the electron as a set of working ideas and experimental results) without further interpretation

The NOA may be adequate for a spectator of the game of physics, but I do not see it as appropriate for a player Fine tells us that NOA makes it easy to adopt "paradigm shifts", but that is passive behaviour Physics, the active game of creating beautiful pictures with predictive power, was played so well by Einstein not least because of his realist faith

Fine rather snidely compares the realist faith to religious faith In the same vein I would add philosopher's faith (in unexamined axiomatic concepts), for it seems each philosopher is refuted by another on such "religious" grounds There is nothing wrong with faith all physicists act on more knowledge than they can prove But in matters of faith, certainly evidence counts The creative successes of realists over the centuries justify their leap of faith more than that of most others And, although one might attribute the success of quantum theory in the past 60 years to nonrealists, in practice they deal with the reality of the concepts they use the way Bohr dealt with a horseshoe He put one on his cottage door, and said, "No, I don't believe in it, but I understand the good luck comes even if you don't believe" □

Making waves on Shelter Island

Ya B Zeldovich

Shelter Island II. Proceedings of the 1983 Shelter Island Conference on Quantum Field Theory and the Fundamental Problems of Physics. Edited by Roman Jackiw, Nicola N Khuri, Steven Weinberg and Edward Witten *MIT Press 1985 Pp 369 $37 50, £37 50*

The proceedings contained in this book are best viewed against the background of the evolution of physics in the twentieth century and, more specifically, against events at the previous Shelter Island conference of 1947 That meeting was organized by Robert Oppenheimer and was attended by many talented scientists who had returned to fundamental research after working on war projects

The intermittent character of scientific progress is now well-recognized, bursts of fermentation of new ideas are punctuated by steady elucidation of all the consequences A Russian poet Tjutchev, practically unknown abroad, said "Blessed are those who come into this world at its fateful moments", for physicists the remark can be paraphrased as "Lucky are those who attend conferences when fresh ideas are in the air"

One such period was between 1905 and 1928, which witnessed the advent of special and general relativity, quantum mechanics, the quantum theory of fields and the theory of antiparticles In the 1930s, development slowed down the refinement of theory was plagued by infinities A theory of nuclear forces was proposed, with heavy particles — mesons — being an essential part of it Particles with approximately the appropriate mass were found in cosmic rays, but the euphoria turned to desperation when they were found not to fit the theory Many eminent physicists believed that a new conceptual framework would be necessary, something as revolutionary as relativity and quantum theory as Bohr is reputed to have said "This theory is not crazy enough to be true"

But the younger generation of the time (and many of the old) were more sober Shelter Island I gave impetus to the work of Schwinger, Feynman and Bethe, whose renormalization programme brilliantly explained the Lamb–Rutherford level shift in the hydrogen atom and the anomalous magnetic moment of the electron Marshak went on to consider the possibility of two mesons the muon as a heavy electron and the pion giving nuclear forces For several decades physics was dominated by ingenious applications of principles formulated before 1930, even gauge theory and quarks fall in this category It was not until the mid-1970s and 1980s that a further wave of ideas arose, and it is these new ideas that are the subject of this volume

In a nutshell, the goal of the old theory was this given the existence and characteristics of particles and fields, how could one move on to calculate all processes, bound states and so on? The new theory has a more ambitious programme It aims at explaining *why* all known particles exist — and determining their masses and charges The same theory also predicts the existence of many as yet unknown particles and fields Very strange — even "crazy" — ideas are needed!

An excellent overall view of how things stand is given in the first paper in the book, where Murray Gell-Mann provides a coherent yet witty account of how theory has developed between the two Shelter Island conferences Here, too, Gell-Mann summarizes the topics treated in detail in the following articles — supersymmetry, Kaluza–Klein multidimensional theories, superstrings, and the new and fruitful symbiosis between particle physics and astrophysics

To a reader not well acquainted with particle physics, I should also add mention of two events of previous history the introduction of Planck units of mass, length and time in 1899, and the appearance of Dirac's famous paper on large numbers in physics the ratio of electrostatic to gravitational interaction, 10^{39} in the atom, for example The modern answer is quite different from that proposed by Dirac, but that does not invalidate the importance of the question he raised

Characteristic of the new wave of ideas is Steven Weinberg's paper, "Calculation of Fine Structure Constants", in which he discusses the now popular idea of higher dimensional space-time manifolds Time and three spatial coordinates describe the usual space-time, while the extra spatial coordinates are assumed to be "compactified" to dimensions of the order of 10^{-32}cm They are not observable as coordinates, but their deformations manifest themselves as fields and particles As shown in Witten's contribution later in the book, the structure of these extra dimensions may explain the spectrum of fermions — the existence of three, and only three, families of leptons and quarks

This is a revival of a theory, initiated in the 1920s by Kaluza and Klein, to unify gravity and electromagnetism For a long time Einstein's own search for a unified theory appeared to be simplistic and to be contradicted by the proliferation of fields and particles found by experimenters Now, however, most theorists are convinced that the time is ripe for brainstorming in this direction but with more dimensions and a peculiar symmetry (supersymmetry) between bosons and fermions

A new branch of physics, as compared with the 1947 conference, is the interdisciplinary study of the very early Universe Then, because of the negative pressure of a scalar field, one had gravitational repulsion instead of attraction and the radius of the Universe grew exponentially Both Guth and Linde discuss the topic (Incidentally, Frenkel and Landau from the USSR were invited to attend Shelter Island I, but neither of them went, Linde, of the Lebedev Institute in Moscow, did attend in 1983, and contributed The ratio 1 0 is a great improvement!) In the 1960s, the big bang theory of the origin of the Universe was supported by the discovery of background microwave radiation in the Universe, and by the theory of nucleosynthesis occurring at temperatures from 3×10^{10} to 3×10^{8}K These energies are within the range of our particle accelerators, results from which have lent further weight to the big bang theory But in attempting to go back to an even earlier stage one enters unexplored territory, and the Universe itself has to play the role of the poor man's accelerator Here the astrophysicist's work is akin to that of the palaeontologist, in which events in a past era must be interpreted from their traces observed today For example, in my opinion (shared by many others, including Gell-Mann) the very charge asymmetry of the Universe, that is, the absence of bulk antimatter, is proof of the instability of the proton, which Earth-bound experimentalists have searched for in vain

Everybody working on or interested in the fundamental problems of physics should read *Shelter Island II* One needs a good grasp of quantum electrodynamics and some special mathematics to appreciate the contents fully, but even those without such knowledge will gain an awareness of contemporary developments in theoretical physics The science-appeal emanating from the book is very strong, I suspect that many physicists will read it initially without understanding everything, and then learn more fundamentals and return to it

Although the conference was held in 1983, the book has not dated very much, the various authors remain leading authorities on their subjects and are now, three years later, still developing the ideas discussed in their contributions Altogether one is grateful to the organizers of the conference and to the editors for bringing together such influential people and for collecting their papers into this excellent book The publishers might consider issuing a cheaper paperback edition so that its contents would be more widely available, especially to students ☐

NATURE VOL 324 20 NOVEMBER 1986

Other people's nuclear weapons

Week-end diplomacy seems to have won Britain a prolongation of its role as a nuclear power, but the time has come to ask when and how this will be attenuated.

THE British government's case for maintaining nuclear forces is far from simple and far from clear. Historically, the British stumbled into making nuclear weapons because, in the late 1940s, it seemed to the then Labour government that this was the natural course to follow in a substantial and technologically advanced country. Over the years, circumstances have changed. The range of Britain's international interests has shrunk to an extent that could not have been foreseen forty years ago, while the country's industrial economy is no longer large enough to sustain the independent development and construction of strategic delivery systems.

The obvious parallel with the present time is that in the early 1960s, when the then Prime Minister, Mr Harold Macmillan (now Lord Stockton), persuaded President John F Kennedy that, if the air-launched nuclear bomb called Skybolt was not available (because it did not function as designed), the British government should be allowed to purchase Polaris submarines instead. But why? In one sense, it is merely right and proper that a government which is a member of an alliance such as the North Atlantic Treaty Organisation (NATO) should make an equitable contribution to its strategic forces, indeed, the British Polaris submarines are operated within NATO guidelines, but with the understanding that they might be withdrawn, and operated independently, if some vital national interest were involved.

But what could those circumstances be? Is not the United States fully committed to the defence of Europe not merely through the formal treaty on which NATO rests but also by the presence both of troops and of strategic missiles on European soil? The simple answer is that these assurances have been insufficient for a succession of British governments, all of which have recognized that circumstances could arise when the United States might shrink from using its strategic nuclear forces, risking retaliation in the process, for the sake of some ill-understood European interest. These dark suspicions have been strengthened by the news from Reykjavik last month.

Negotiations

Whether Britain and France will be able indefinitely to continue in that frame of mind is another matter. Everything will depend on what happens in the negotiations on strategic arms still continuing at Geneva. After Reykjavik, and the recognition by the two most powerful people in the world that even they cannot magic out of thin air lasting agreements on difficult questions in a dozen hours of conversation, it is inevitable that strategic arms control will be regarded as a matter for the long haul, the bilateral negotiations at Geneva will (with luck) be prolonged into the next decade, and more attention will be paid to other aspects of the relationship between the major powers. But the time will come when, again with luck, there will be another proposal that the balance between both strategic missiles and missiles of intermediate range should be struck at a lower level than at present. At some stage, the point will (with luck, again) arrive at which the British and French nuclear forces stand out conspicuously. Then the superpowers will be pressing to see these independent nuclear forces cut back to size. The United States, having helped Britain to build Trident submarines, will be wanting to see them scuttled. That will be an awkward conversation for some future weekend at Camp David.

The British position on this forseen dilemma is, fortunately, explicit. In the first place, the submarine missiles are regarded as strategic weapons, contributing now to the strategic deterrent of NATO as a whole but also intended as a means by which Britain might threaten even a more powerful potential adversary with an unacceptable degree of retaliatory damage. Theoretically, the French regard for nuclear weapons is very much the same, they might not be sufficient to influence events on the global stage, but they would surely 'tear an arm' from an attacker, and give him pause. But the British government has also gone so far as to consider when it would be proper to think of limiting its nuclear forces, saying that this would be acceptable as part of a more general agreement for the substantial reduction of nuclear forces everywhere.

Unfortunately, this undertaking is not nearly as clear as it might be. The British government argues that, because its weapons are strategic, their number should not be affected by an agreement on the numbers of superpower nuclear weapons deployed in or against Europe, which makes sense. But the prospect that there may be very substantial reductions of European nuclear forces can only strengthen the British government's unspoken fears that Europe may one day be left to its own devices, whence in part Mrs Thatcher's visit to Washington at the weekend. The snag is that the British position is vague on what would happen if there were also a substantial agreement on strategic forces might be held to provide a licence for conventional wars in Europe, in which West European states would be disadvantaged. So British governments will be tempted to hang on to their nuclear weapons through thick and thin.

The lessons to be learned from these tortuous arguments are several. First, Britain's susceptibilities about its nuclear weapons mirror those of other European states about other aspects of their arrangements for defence. British nuclear weapons would indeed be an impediment to sudden and drastic reductions of nuclear arms along the lines fancied at Reykjavik, but so would be the political protestations of other European states, from which it follows that the superpowers must aim in their negotiations at a balanced package of arms control agreements covering not merely strategic and intermediate nuclear missiles but conventional forces and even the temper of East–West relations. On that score, the Europeans have a case. But the United States also has a right to expect that the British and French nuclear weapons will not be impediments to reasonable arms agreements that may in future be reached with the Soviet Union. Indeed, it would have been natural that President Reagan should have broached the question with Mrs Thatcher at the weekend, while confirming that Trident should succeed Polaris. And, given governments' temptations to hang on to weapons in the face of arguments to the contrary, there is the strongest case for asking that the British government should now be prepared publicly to define the circumstances in which it will let go. France, which is a harder case, should be persuaded also to follow suit.

Carnegie's misdiagnosis

A new study of undergraduate education misses an opportunity to tell what is really wrong.

US ACADEMICS and their followers, in one of their periodic fits of introspection, have been giving pious attention to a report from the Carnegie Foundation for the Advancement of Teaching on the state of higher education and, in particular, to its judgement that, "driven by careerism and overshadowed by graduate and professional education, many of the nation's colleges and universities are more successful in credentialing (*sic*) than in providing a quality education for their students". There will be few who disagree with that, but the foundation's study, *College — the undergraduate experience in America*, by Mr Ernest Boyer, is most notable for what it has left unsaid.

Carnegie is, naturally, right to be troubled by the lack of individual attention given to undergraduates and to sympathize with them in the hard choice of a course of study. Then few will quarrel with Boyer's plea for better personal advice to students, especially during the difficult transition from high-school to college. And nobody will argue against the case for higher standards of literacy. But the argument hangs too much on the subjective experiences of undergraduates and teachers, as reported and, often touchingly, recorded. This preoccupation with tensions between "individual interests and shared concerns" means that some of the urgent questions about the future of higher education in the United States are mis-stated.

One is the pattern of the curriculum. US universities have always required less specialization than have universities elsewhere, and deserve credit for it. Their accessibility is unmatched anywhere in the world. But the worry now is that things have gone too far, and that US undergraduates have too much latitude to choose from a curriculum increasingly resembling a supermarket for credit courses, with students free to experiment as they please until the required number of credits is reached. The Carnegie report rightly raises this important issue, with which William J. Bennett, the US Secretary of Education, startled some of those at Harvard University's 350th birthday celebrations earlier this year, taking Harvard as his inappropriate example. Carnegie's remedy for the laundry-list approach to education is to call for a core curriculum. The need for some high-level coordination cannot be denied. But if Carnegie wishes to be taken seriously, it must devise a more persuasive core than the amalgam now put forward, an "integrated core" that would include language, art, history, institutions, nature ("the ecology of the planet"), work ("the value of vocation") and identity ("the search for meaning"). All this, but no general science course?

The Carnegie study also draws attention to the conflicts that can arise in research universities between the demands of teaching and of research. The story is familiar: because academic prowess is measured largely by published research papers, faculty members devote their best efforts to excellence in research, sometimes at the expense of teaching. Boyer's suggestion that research universities should establish a new rank of "distinguished teaching professor", extending status and salary incentives to outstanding teachers, might serve well in some colleges and universities, but ignores the frequency with which excellence in teaching and in research go together, hand in glove. In the end, the research universities will have to deal with this internal conflict internally, by requiring that faculty members are not so distracted by external interests and commitments as to impede their discharge of their academic responsibilities, to students as well as to research. This goal will not be easily won, but the research universities eager that their reputations should survive will give it more attention than has been the habit in recent years. The professorial status of good teachers is a palliative only.

The Carnegie Foundation would also have done education a greater service if it had tackled some of the problems of higher education that are beyond the control of the universities themselves. The most immediate threat is the accumulated effect of the dereliction of university research facilities and cutbacks in support for students. Many of the institutions that have served the United States well in the past, the less well-known universities that dominate the Boyer's survey in particular, are now ominously stretched. Government officials are fond of pointing out that support for basic research at universities has increased in recent years, which is true. But the increase followed a long decline during the 1970s that has not yet been made good. Decaying facilities and equipment are depressingly common on all but the most successful campuses. Federal support for university research facilities dropped from $404 million in 1966 to a low point of just $37 million in 1981 (1981 prices). Support for graduate students in the sciences has fallen by about a half since 1969. The efforts of the National Science Foundation to promote excellence in science education, all but abolished by President Reagan at the start of his first term of office, are improving, but slowly. Small wonder that the proportion of bachelor's degrees in physical and biological sciences has fallen since the late 1970s, with even engineering starting to tail off in 1985. Yet fewer undergraduates now means fewer faculty members in ten years' time, less research and, probably, less teaching. Unless the federal government decides to act, these are the circumstances that will condition some future Carnegie report on the parlous condition of higher education in the United States at the end of the decade. □

Fire without smoke

Two retracted papers do not make a scandal, but too much reticence about the circumstances may.

DANA-Farber Cancer Institute has a problem (see page 197). It has announced that two papers describing a T-cell activating substance called interleukin-4A are being retracted from the journals in which they were published. This is certainly not the first time that scientific papers have been withdrawn, and it will not be the last. It is very much to the credit of Dana-Farber that the retractions were issued as soon as the errors in the data were discovered.

Where Dana-Farber's problem lies is in the way it described — or more properly failed to describe — the reasons for the retraction. Obviously there are many reasons why papers may have to be retracted. Cell culture contamination, reagent impurities, inadvertent miscoding of results can all be discovered, long after the fact, even in the most careful and thorough laboratories. But Dana-Farber has not invoked any of these readily believable explanations, choosing to make the blunt statement that an investigation is under way, and that retraction letters have gone out. This approach can only leave a cloud of suspicion hanging over the institute. What sort of investigation is it that can immediately conclude that the data upon which a paper is based are incorrect and not reproducible without saying how that fact is known?

Unhappily, there have been all too many recent instances in which falsification of data has brought laboratories into trouble. By declining to comment about its investigation, Dana-Farber, perhaps unwittingly, merely encourages speculation. Officials at Dana-Farber will correctly say that it is unfair to make allegations that could have a profound influence on a scientist's career before they are completely investigated. But silence is not the answer. Surely it is possible to say what first aroused suspicions about the data without jeopardizing future investigation? Surely retractions with no explanation will focus interest on the case longer than a simple statement about the circumstances as they are at present known? The scientific community should be credited with the good sense to understand the distinction between an investigation and a final judgement. □

Research publishing

Interleukin disappears from the literature

Boston

Two papers from Dr Ellis Reinherz's laboratory at Dana–Farber Cancer Institute that announced the discovery and properties of a T-cell activating substance termed interleukin-4A(IL-4A) have been retracted by the authors The reason given for the retraction is that the data are incorrect and are not reproducible The authors, in other words, no longer claim to have proof of the existence of IL-4A originally hailed as the chemical messenger that amplifies the body's immune response by turning on resting T cell's, through its interaction with the T11 protein at the surface of the T cell

The papers being retracted were published in *Science* (**231**, 1118, 1986 by Claudio Milanese, Neil E Richardson and Ellis L Reinherz) and the *Journal of Experimental Medicine* (**163**, 1583, 1986 by Claudio Milanese, Robert E Siliciano, Reinhold E Schmidt, Jerome Ritz, Neil F Richardson and Ellis L Reinherz) Letters of retraction are being sent to both journals

An *ad hoc* committee of scientists from both within and outside Dana–Farber is investigating why the papers need to be retracted Both Reinherz and David Kiszkiss, director of research at the institute, refused to comment on the reasons the data became suspect, how the data were proved incorrect, or why a retraction of the articles was necessary even before an investigation was completed It is possible that litigation may result, according to Reinherz, but a final decision will be up to Dana–Farber and its parent Harvard Medical School or perhaps the National Institutes of Heath (NIH), Kiszkiss says

Kiszkiss refused to comment on the process of data review at Dana–Farber or in the Reinherz laboratory Dr Sheldon Wolff of the New England Medical Center, says any person in a laboratory understands there will be efforts to reproduce all published data There is no way the principal scientist can be expected to stand at the elbow of everyone working in a laboratory, says Wolff The work of Reinherz is unanimously described as "impeccable" by others in the field

The withdrawal of the IL-4A papers means there is now only one well-studied candidate for a T11 ligand, a molecule termed LFA3 The data supporting the existence and activity of this molecule are so convincing, says Dr Peter Beverley at the Imperial Cancer Research Fund in London, that "a number of people were sceptical of the dramatic announcement" of IL–4A According to Dr Stephen Shaw of NIH, a principal investigator of LFA3, there is much interest in finding the one or more molecules that interact with T11, also called CD2 T11 is a marker on T cells thought to be involved in adhesion of lymphocytes and triggering of T-cell activation IL-4A was described as soluble, of low molecular weight, and responsible for triggering resting T cells LFA3 is a much larger cell-bound molecule responsible for lymphocyte adhesion

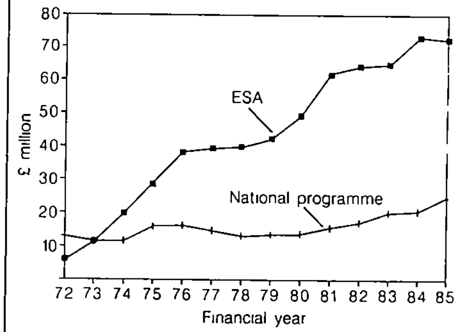
Shaw says he originally accepted the IL-4A data because they came from the Reinherz laboratory and because there is room on the T11 molecule for two different recognition sites He also thought IL-4A could be a soluble fragment of LFA3 Even though there is no longer proof of the molecule termed IL-4A, he says, other ligands for the "popular and trendy" T11 molecule may exist, including (he speculates) a soluble form of LFA3

Elizabeth Collins

British space

Waiting for an increased budget

THE British National Space Centre (BNSC) this week celebrates its first anniversary still awaiting the government's response to its 15-year plan for Britain's presence in space The blueprint, if accepted, will mean a substantial increase in the £108 million a year that Britain now spends on international and domestic space projects



BNSC seeks more funds for space research and a narrowing of the gap between international and domestic projects

Britain is under pressure from the United States and Europe to invest heavily It was the need to respond sensibly to an invitation to participate in the US Space Platform that inspired the creation of BNSC (see *Nature* **318**, 305, 1986)

A ministerial council meeting of the European Space Agency (ESA) in Rome in 1985 generated pressure from Europe The meeting approved in principle a number of new programmes that would require members' contributions to be increased by 70 per cent in the next three years France, for example, which already spends five times as much as Britain, has decided to increase its budget by 40 per cent, bringing the total annual expenditure on space to £700 million

Roy Gibson, director general of BNSC, says "the European scene is going on, whether we are ready or not", and that BNSC must have a positive response from government within the next few weeks if proper preparations are to be made for the ESA ministerial council meeting next June at which the final touches to the ESA programme, some lasting more than a decade, will be made

"Last year we weren't too worried about this deadline in June 1987 now we're getting a big edgy because we need these decisions in order to give us the best bargaining position inside ESA "

The British space plan, he says, will require substantial international investment and the domestic budget must be increased to ensure industrial back-up to exploit the new technologies Much of the money for Britain's contribution to the space platform project, Gibson believes, must come from the government Although the private sector may eventually benefit, it would find it hard to justify a commercial investment at this stage "I think it would be very wrong to tell government that it's going to make a lot of money straight away "

BNSC wants the government to commit itself to plans that will span more than a decade and to allocate money at least three years ahead to allow industry to respond and plan accordingly

To that end, the BNSC plan details the principal areas in which the United Kingdom must develop These are space science, remote sensing, microgravity, telecommunications (with particular emphasis on mobile communications on land, air and sea), space station, ground/test/reception facilities, data processing and enabling technologies

The present budget is culled from the space funds of the Department of Trade and Industry, the Ministry of Defence, the Natural Environment Research Council and the Science and Engineering Research Council The 280 members of staff are spread between London, the Rutherford Appleton Laboratory in Oxfordshire and Farnborough in Hampshire The next stage would be to create a permanent role for BNSC and perhaps a permanent home

Bill Johnstone

Soviet accusation

Plagiarism charges levelled

Two leading members of the Academy of Sciences of the Byelorussian SSR have accused a US professor, Dr Hollis B Chen, of plagiarism Writing in the Russian weekly *Literaturnaya Gazeta,* Dr Mikolaj Barysevic, president of the Byelorussian Academy, and Dr Barys Sciapanau, a three-times State Prize winner, have accused Chen of pirating chapters 3–6 of his textbook *Theory of Electromagnetic Waves — a Coordinate-Free Approach* (McGraw Hill, 1985) This material, they claim, was lifted without acknowledgement from two monographs by Dr Fiodar Fiodarau, son of the Byelorussian writer Janka Maur Fiodarau is a leading light of the Byelorussian Academy, and is secretary of its section of physical, mathematical and technical sciences

According to Barysevic and Sciapanau, the "coordinate-free" method was pioneered by Fiodarau more than 30 years ago On the basis of this "fruitful approach", they say, he has published six monographs and "hundreds of scientific articles" Chen's work, they allege, is based on two of three works, the monograph *Optics of Anisotropic Media* (Minsk, 1958) and the book *Theory of Gyrotropy* (Minsk, 1976) Both works are fairly obscure, having been published, the critics admit, "a fairly long time ago, in a small edition, and from an obscure scientific press (*Navuka i Technika,* Minsk)

Their accusations may be summarized under four points

- Chen, they say, claims on the blurb that his method is new, and that the book "for the first time treats the essence of the subject fully on a coordinate-free basis",
- Chen's bibliography makes no reference to Fiodarau in its more than 200 items,
- Chapters 3–6 of Chen's book are almost completely copies from Fiodarau, and, in particular, the diagrams have been lifted unchanged,
- Chen's book, "contrary to academic tradition", does not give references, within the body of the text, to the works mentioned in the footnotes This, say the critics, is to avoid revealing how much material is derived from Fiodarau

The complaint ends by listing the many learned societies to which Chen belongs, in terms that leave no doubt that, in the opinion of the critics, he should be expelled as "one of the most cynical and shameless plagiarists in the history of science"

Examination of the book does not appear to substantiate these allegations Chen's work, a textbook for final-year undergraduate and graduate students, does not claim any novelty of method, although his preface does speak of its being an "alternative approach", a coordinate-free approach, and notes that "the organization of the book is somewhat different from that normally found in books on electromagnetics" His diagrams, in the disputed Chapters 3–6 in particular, seem standard vectorial representations of such phenomena as refraction and reflection But Chen in fact makes little claim to novelty and was not, he said, responsible for the jacket In a statement to *Nature* last week he says that he had never claimed the creation of a new method, and maintains that he had relied heavily on the previous work of others The book is not, he emphasizes, a research monograph but a university text He therefore makes little reference to work published in languages other than English He has no knowledge, he stresses, of Russian

Vera Rich

Chen's statement

"This book is intended as a text for seniors and first-year graduate students, not Research monograph. The development of the book relies heavily on my previous research work on waves in plasma and the published work of the others as stated in the preface. I have never claimed the creation of the new method. In fact, the vectors and dyads were invented in 1881 by Professor J.W. Gibbs of Yale University Unfortunately, I do not read Russian and most of my references were in English. This is because the focus was on developing a strong textbook in electromagnetic waves rather than a comprehensive research monograph". □

Australian universities

Going private pleasantly?

Sydney

Plans for a private university that would break the public monopoly in higher education are attracting strong opposition from academics, in particular university staff associations and teachers' groups The address of the Bond University of Technology is Miami, Surfers Paradise, on Queensland's Gold Coast, one of Australia's most pleasant areas It will open its doors in 1989 to a first intake of 1,000 out of a planned total of 10,000 students, many of whom will be from overseas, particularly from Japan and South-East Asia But the organizers hope that at least half of the students will come from Australia's free government tertiary institutions

The university is the brainchild of businessman Alan Bond, of America's Cup fame Funds for the university will come equally from the Bond Corporation and a Japanese development company represented by Dr Bungo Ishizaki of the Osaka Univeristy of Commerce The university will be run as a non-profit body with operating costs covered entirely by student fees The backers intend to make their investment pay by capitalizing on products and inventions arising from research carried out in the university

High salaries will be offered to attract talented staff and the position of vice-chancellor is being advertised at a salary of A$150,000, substantially higher than that for a similar post at an existing university

Criticisms of the Bond Univeristy include doubts about the standard of its courses and whether or not the range of subjects to be offered warrants the title of university The main reason for opposition seems to be the threat it poses to Australia's egalitarian education system by creating an elite of those who can afford to pay One fear is that, once the institution is established, it may be successful in pressing the government for assistance, and that with the proliferation of such private institutions, existing establishments will be left with an ever smaller cake to cut up Others worry that the institution will become a last resort for those not bright enough to gain admittance elsewhere And there is concern over the destabilizing effect of the high salaries on the rigid salary structure of the government institutions

Supporters feel that the quality of present universities is suffering because of the restrictions that accompany government funding Dr Ian Bassett, a senior lecturer in physics at the Univeristy of Sydney, believes that salary flexibility is vital to attract outstanding people Present arrangements of the Commonwealth Tertiary Education Commission (CTEC) prevent universities from offering higher salaries even if the extra comes from private sources When the Univeristy of Sydney recently gave its vice-chancellor a few thousand dollars extra, the same amount was taken out of the following year's grant And the present rigidity in salaries fails to recognize that it is more difficult to attract talented staff to some disciplines than to others

In defence of its own plan, the Bond Corporation points out that it is in line with the government's policy of encouraging more contact between academics and industry Furthermore, with a rapidly growing population of 370,000, the Gold Coast region is the seventh largest population centre in Australia and the only one of its size without a univeristy The present climate of restraint in government spending is unlikely to give the region another chance to get one say the supporters of the Bond plan

Charles Morgan

Nuclear energy

India joins enrichment club

New Delhi

India has developed the capability to enrich uranium, according to Dr Raja Ramanna, chairman of the Atomic Energy Commission (AEC); he did not reveal the size of the enrichment plant nor the amount of U-235 produced. Ramanna was speaking at a press conference and reacting to US press reports that Pakistan is now able to make bomb-grade uranium.

For the past four years, the Bhabha Atomic Research Centre (BARC) has been operating a gas centrifuge pilot plant at Trombay near Bombay. Its operation and progress have been closely guarded secrets until now. Unlike Pakistan, which relied on secret imports of design and parts for its Kahuta enrichment facility, BARC is believed to have designed the plant itself.

There are rumours that, based on the pilot facility, BARC is setting up a full-scale gas centrifuge plant near Mysore in Karnataka state in South India. But Iyengar, in an interview on All-India Radio, said the enrichment project was part of BARC's efforts to develop expertise in all aspects of nuclear energy and that there was no plan to set up a bigger plant.

India has no need for enriched uranium as its Candu-type reactors are based on natural uranium fuel and heavy-water moderator. Only the two US-built light water reactors (LWR) at Tarapur at present depend on U-235 fuel imported from France. Under an agreement with the United States, US permission is required for operating the reactors with India's own enriched uranium fuel. According to Iyengar, the enriched uranium will be required for nuclear physics experiments.

India is self-reliant in the total nuclear fuel cycle technology — from mining uranium and commissioning power plants to reprocessing spent fuel. Enrichment was one area where it lagged behind. Having developed the gas centrifuge technology, India is now on equal terms with Pakistan, but AEC sources have dismissed speculation that India's enrichment activity is related to a weapons programme.

US news reports that Pakistan is on the verge of building a bomb have undoubtedly caused alarm in India, but the government has said it will not take any hasty decisions about going nuclear. Replying to questions about the possible nuclear threat from India's neighbour, Mr Natwaar Singh, Minister of State for External Affairs, told parliament that India "will keep its powder dry" while at the same time exploring all avenues for preventing a nuclear race in the subcontinent. India, which conducted a nuclear test at Pokhran 12 years ago, has consistently denied having a weapons programme.

Meanwhile, AEC has announced an ambitious plan to build 22 more nuclear power plants in the next 15 years to raise India's nuclear power capacity from the present 1,100 MW to 10,000 MW. Ten of the reactors will be 500-MW units (now in the design stage) and the rest will be similar to the 235-MW plants in operation in Madras and Rajasthan. The 15-year plan would cost $14,000 million at 1983 prices. Because government resources are limited, it has been decided to bring nuclear power generation under a public limited company that will raise funds through the issue of bonds and shares. Although AEC is confident of launching the Nuclear Power Corporation, it remains to be seen whether the Indian public will invest in this programme after Chernobyl.

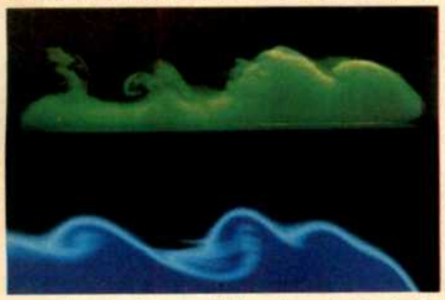
Storm flow simulation by computer

Washington

A numerical simulation of thunderstorm outflows by Kelvin Droegemeier of the University of Oklahoma is being used to program a 727-passenger jet flight simulator at the Federal Aviation Administration's training academy in Oklahoma City. It is hoped that pilots can learn to recognize and avoid dangerous wind shear associated with outflows, which has caused several fatal crashes.

Droegemeier has produced a film of his simulations, which were run on a Cray X-MP supercomputer at Omnibus Simulation Inc. of Los Angeles. The blue image shows a still from the numerical model; the green image shows a laboratory tank study in which the same phenomenon is modelled by releasing salt water into less dense fresh water. The simulation, which has about 40,000 grid points, reproduces clearly the features seen in tank studies 20 years ago. The turbulent eddies on top of the outflow in both images are corroborated by Doppler radar images of real outflows, and probably explain the seemingly random pressure fluctuations observed on the ground beneath. Production of Droegemeier's film was paid for by the National Science Foundation's Office of Advance Scientific Computing.



Tim Beardsley

AIDS

German survey's gloomy outlook

Three-quarters of those infected with the AIDS (acquired immune deficiency syndrome) virus will enter the final and fatal stages of the disease within seven years, according to a research team from the University of Frankfurt.

The predictions from the study, claimed to be the first long-term project in Europe, are based on "continuous observation" of 543 patients, largely the sexual partners of the first AIDS victims to die in Frankfurt, who have been attending outpatients' clinics since 1982. On the basis of the rate of deterioration of these patients — 377 proved positive in original antibody tests — and from computer forecasts, the researchers conclude that half the antibody carriers will have progressed to the final stage of AIDS within five years of first exposure and three-quarters within seven years.

The research team is led by Professor Eilke Brigitte Helm from the Zentrum der Inneren Medizin at the University of Frankfurt and the findings are published in the *Deutsche Medizinische Wochenschrift* (No. 32/32, 1986). The team placed all the patients in one of four categories, depending on the seriousness of the symptoms. They were those whose antibody tests proved positive but who had no obvious sign of the disease; those with a slight immunological weakness and showing symptoms of lymph-node swelling; those with pronounced immunological defects; and those with the full symptoms of the disease. The progress of the patients was monitored for three years.

At the end of that period, only 30 of the original antibody-positive patients were still healthy and, within a year, half of the patients with no symptoms moved into the next category. Within two years, half of those with slight or pronounced immunological defects were entering the final stages of the disease or suffering severe disintegration of their defence systems. With one exception, all those in the final stages of the disease died within two years.

According to the researchers, the belief that AIDS would develop only in a minority of cases infected with the virus is unfounded. The predicted size of that minority has increased with time from 5 or 10 per cent to at least 30 per cent in some cohorts of patients, but the German prediction of 75 per cent is unprecedented.

Technology

Genentech buys out partnerships

Washington

GENENTECH Inc., one of the leaders in US biotechnology, has decided to reap an early harvest by announcing plans to buy out two of its research and development partnerships early. A limited partnership is a means by which outside investors support part of a company's research and development programme, sharing the profits if it succeeds and otherwise being able to set off the loss against taxes.

Genentech Clinical Partners Ltd (GCP) and Genentech Clinical Partners II (GCP II), have provided support and shouldered risk while Genentech's seedling products, including the human growth hormone Protropin, tissue plasminogen activator Activase and gamma interferon are being developed and tested clinically.

According to the original agreements, Genentech would not have bought out the partnerships until two years after the products from each of them had received approval from the US Food and Drug Administration (FDA). This would have been 1988 for GCP, as FDA approved Protropin this year, and a later date for GCP II, depending on FDA approval for the marketing of Activase.

Buying out the partnerships will give Genentech exclusive US rights for Protropin, Activase and gamma interferon, and all the associated profits. The partners will be offered 3,000 shares of Genentech common stock for every $50,000 partnership unit in GCP and 2,500 shares for every similar unit in GCP II. If the stock price on the date of the transactions remains at $80, as expected, each $50,000 investment in GCP would receive Genentech stock valued at $240,000 and in GCPII stock valued at $200,000.

By acting now, before the partnership agreements have expired, Genentech avoids buying completely developed products that would have to be capitalized and amortized. This development shows Genentech's faith in the products developed under the partnership agreements; on Wall Street, Genentech's stock rose by $12.75 per share on the day after the proposed buyout was announced. The price is now about $85.

Genentech is one of the first US biotechnology companies to become profitable. It recorded a profit of $5.6 million ($0.18 per share) in 1985, and its financial report to the end of September this year shows a net income of $8.2 million, an earning for each share of $0.23. Although the early promise of big profits for 1986 will be diluted by the one-off expense of the GCP II buyout, profits for 1986 are likely to be double those for 1985.

Genentech is also now planning a two-for-one stock split and intends, like many other leading US companies, to reincorporate in the state of Delaware to benefit from the favourable legal climate there.

Carol Ezzell

Student squeeze in West Germany

Hamburg

WHILE the universities in West Germany are still groaning under the burden of too many students — 1.3 million are sharing 850,000 places (see *Nature* 322, 197; 1986) — they are preparing to compete for students in the decade ahead. The number of school students is falling; the era of expansion is coming to an end.

A detailed analysis carried out at the centre for the study of regional development at Giessen and sponsored by the Deutsche Forschungsgemeinschaft (DFG) has shown that the new student generation will prefer big and old universities, so that the new and smaller institutions, particularly in Bavaria, may "have to fight for their survival".

The study is based on official university statistics, interviews with school leavers and figures from the Zentralstelle für die Vergabe von Studienplätzen (ZVS). The results are alarming for the cities concerned. Giessen, for example, with 17,500 students among its 70,000 inhabitants, will lose more than 4,000 students.

Other universities, many of which are at present overcrowded, will not suffer so greatly. The analysis, which was carried out by Professor Ernst Giese, concluded that 22 out of 52 West German universities are "above average", in being chosen by more than 2 per cent of new undergraduates. The University of Munich attracts 8 per cent, followed by Cologne, Hamburg, Hannover, Münster, Munich (Technical University), Aachen, Bonn and Berlin (Free University) with between 5.49 and 3.5 per cent.

Old universities are preferred because of their traditions but also because of the recommendations of previous students. Universities such as Bremen, Frankfurt and Marburg, which were considered to have left-wing tendencies are well regarded now.

One of the ways in which the universities will compete is by setting up special study centres concentrating on specific subjects such as solid-state physics at Stuttgart, genetic engineering at Heidelberg and Würzburg, plant biotechnology at Hamburg and Cologne and information technology at Karslruhe. Jürgen Neffe

Chinese – US collaboration

NSF refuses fees

Washington

THE National Science Foundation (NSF) is digging in its heels against what it sees as unreasonable charges levied by the Peoples' Republic of China for US field trips in the country. Officials say the Chinese policy of charging for field trips is contrary to the spirit, if not the letter, of government agreements on scientfic exchanges, and have given notice that NSF will not pay for a return visit next year by a US team taking glaciological samples in the Quilian mountains in Tibet.

The US team, headed by Lonnie Thompson of Ohio State University, spent 28 days last summer in a remote glacial area 1,000 km west of Lanchow, working with scientists from the Lanchow Institute of Glaciology and Geocryology. According to NSF's Eugene Bierly, China at first asked for $100,000 to defray expedition expenses, but after negotiations, the figure was reduced to $80,000. Thompson plans to return next summer to bring back ice-core samples, but NSF says it will not meet field-trip expenses again on the grounds that they violate the "receiving side pays" convention that underlies the US – Chinese agreements.

Bierly said there would be no question of charging Chinese scientists for field trips in the United States, and expressed the fear that budget cuts at some Chinese research institutes might tempt them to make deals with scientists from other countries, perhaps allowing priority of access to those who pay well. Bierly said NSF is determined to "hold the line".

Others report similar difficulties with fees for access to China. Craig Black of the Los Angeles Museum of Natural History said last week at a meeting of the National Science Board that charges for biological field trips were commonplace and that it was "almost becoming competitive". Officials at the meeting were alarmed by reports of a Japanese–Chinese agreement on glaciological research according to which, it is said, Japan will pay $1,000,000 and donate four expedition vehicles in return for access to a large tract of China. NSF officials say the foundation would be unable to offer funds on that scale.

Thompson disputes NSF's figure of $80,000 for the fee for last year's Quilian expedition, saying it was only $40,000. The fee was, he says, reasonable for the level of logistical support provided, and that it "would be a good deal in any other country". NSF meets expedition costs in countries with which there are not collaborative agrements. But Thompson says he has agreed with the National Geographic Society that it will pay the expedition costs next year, so NSF's stand should not imperil his venture. **Tim Beardsley**

Rhine pollution

Death of Europe's sewer?

In the French city of Strasbourg, on a tributary of the Rhine just 100 km downstream from Basel, feelings are running high, as they are all along this long river. Demonstrators gathered in Strasbourg and other riverside towns on Sunday carrying placards with messages such as "Poison ou poisson: il faut choisir" ("Poison or fish: we must choose"). Some fish have survived, but are polluted, and fishing has been banned for six months along the upper Rhine and its canals.

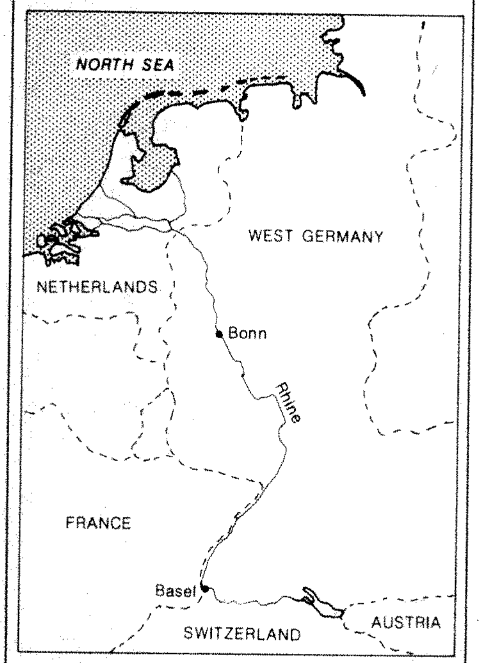
The Rhine seems 'dead' for 100–200 km downstream of Basel in northern Switzerland after the fire in the Sandoz chemical plant led to the discharge into the river of up to 32 pesticides, fungicides and other agricultural chemicals. One of the most important, 'disulfeton', is said to be twice as toxic as potassium cyanide; the average dose to kill 50 per cent of rats (the LD_{50} criterion) is about 5 mg kg^{-1} compared with 10 mg kg^{-1} for potassium cyanide.

These facts emerged after the owners of the factory made public a list of the 1,000 tonnes of chemicals stored on the Basel site. Disulfeton has been detected as the principal pollutant from the accident as far as the Dutch border, 600 km downstream from Basel; but by this point the disulfeton had been greatly diluted to around 2 mg l^{-1} of Rhine water, according to informed sources.

Sandoz and the Swiss Federation have admitted liability for the accident, which occurred after firemen had flooded Sandoz's Basel factory with water during a fire, to the extent that a dyke was breached and a toxic 'soup' of some 10–30 tonnes of agrochemicals was released into the Rhine. Mercury-based fungicides such as tillex as well as disulfeton and other organophosphorus compounds were in the mixture, which killed fish, normally resistant eels and insects. The effects on plant life are as yet unknown, and although little organo-mercury was detected downstream, there are fears that such chemicals have been deposited as sediment close to the release point, where they may be slowly released to the food chain for some time.

Thus, according to European environmentalists, the damage has been "enormous". According to the European Environmental Bureau, an organization that acts in Brussels for a number of European environmental groups, the Rhine was beginning to recover until this accident. Industry had been reducing its emissions under a combination of voluntary and statutory controls, to the point where fishermen were beginning to look for salmon at Basel. But this accident released as much pollution in a couple of hours as the Rhine normally receives in a year. "It's set the clean-up back a decade", a bureau spokesman said.

Meanwhile, people are despondent about the months ahead. The proprietor of one fishing tackle shop said she had had no customers for 3–4 days and expected none now until the spring. Did she expect any compensation from the authorities? She gave a resigned shrug of the shoulders.



Nevertheless, there is no doubt that the accident has set the European environmental movement and the legislators a good few steps forward, just as the Chernobyl accident gave a boost to the anti-nuclear lobby. Last week, the European Commission was pointing out how many countries have failed to put into effect the 'Seveso directive' of 1982, in which European Community countries agreed (subject to the passage of relevant national legislation) to impose controls on chemical factories. This followed an accident at Seveso in Italy in which a large area was contaminated by dioxin.

But four years after the directive, the Commission is satisfied only with legislation enacted by Denmark, France and Britain. The Netherlands, one of the loudest complainants against the Sandoz accident, has failed to apply the Seveso directive's principles on worker protection; West Germany has problems in the application of rules on the storage of dangerous substances; Greece's legislation has been too vague and "inadequate"; and Italy, most affected by Seveso, has not applied one of the directive's most crucial elements, a requirement to be placed on companies regularly to inform the authorities and their workers of the processes taking place in a factory, of the chemicals stored and of emergency plans.

The Commission is now planning action against defaulting countries, but to begin with is only taking on a minnow — Luxembourg — in the European Court; with the rest, it has satisfied itself with sending stern diplomatic notes.

Meanwhile, countries belonging to the governmental International Commission for the Protection of the Rhine met in Zurich last week, heard contrite Swiss apologies and offers of damages (to a scale as yet undetermined), and set in motion the investigation of measures that would considerably tighten up controls and safeguards on Rhine industries. Switzerland itself will consider adopting national legislation along the lines of the Seveso directive of the European Communities — although as a non-member it has no obligation to do so — and there is now great pressure for Switzerland to sign an international convention that would oblige Swiss companies to inform their national neighbours of their activities, safety procedures and contingency plans.

The members of the International Commission have also decided in principle to apply to the Rhine the principles of the European convention on the reporting of oil releases at sea (Switzerland was very late in informing its downstream neighbours of the Sandoz release) and to set up an insurance system equivalent to TOVALOP, the tanker owners' voluntary agreement on liability for oil pollution. Any new conventions of this kind would of course apply to all forms of pollutant release and not just to oil. **Robert Walgate**

• Chemical accidents and spills are not confined to Western Europe. During the past few weeks, several incidents have been reported from the Comecon bloc.

On 1 November, at the chlorine and PVC works in Devnya (Bulgaria), there was an accident in which several people were killed, which destroyed the control rooms of two sections of the plant and also the finished products store, and which was apparently caused by rupture by an inadequately maintained pipeline.

On 11 November, in the Buna chemical works in East Germany, a hot-condensate condenser was destroyed by excess pressure, with four workers seriously injured and "considerable damage to property". And on 12 November, Prague radio reported that an accident in the Ostrava sewerage system had led to the discharge of heating oil into the rivers Lucina and Ostravica, and then into the Oder. The damage, the Chechs said, was expected to be long-term because of contamination of the river banks, but "drinking water has not been affected". According to the East German Ministry for Environmental Protection and Water Management, the spillage was not expected to affect the East German reaches of the Oder. **Vera Rich**

Genetic manipulation

Living outside regulation

Washington

A GENETICALLY altered strain of yeast designed to produce a low-calorie beer will soon be churning out trial brews at the Brewery Research Foundation (BRF) in Surrey, England. BioTechnica International of Cambridge, Massachusetts, chose to test its new creation outside the United States in part to postpone facing the regulatory process awaiting it in this country.

BioTechnica has so far produced only 10 millilitres of beer in the laboratory to test the process, and is prohibited from producing more than 10 litres by the Cambridge Biohazards Committee. To do testing on a larger scale, BioTechnica sought out BRF in England because there is no equivalent brewing test facility in the United States. But Roger Yocum, director of BioTechnica's yeast research division, makes no bones about the fact that testing the new yeast will probably be much easier in England.

BioTechnica International has been working for more than three years to produce a strain of *Saccharomyces uvarum* (also called *S. carlsbergensis* or brewers' yeast) containing a gene from the mould *Aspergillus niger* encoding for a glucoamylase enzyme. So-called lite (for 'light') beers are less fattening because they contain less starch than standard brews. By introducing a glucoamylase into brewing yeast, the beer can be produced faster and without other additives to remove the starch.

John Hammond, a biochemist at BRF, says that so far all work on the yeast has involved less than 5 litres, and all brews have been pasteurized to kill the yeast. But an unpasteurized beer, such as is provided to bars and restaurants, could contain live yeast, raising the issue of environmental release of what is an intergeneric organism. Hammond says BRF will consult with the Advisory Committee on Genetic Manipulation and other relevant governmental agencies before proceeding with any large-scale work with BioTechnica's yeast. But Yocum hopes that any US decision whether to permit environmental release of the new yeast will be clarified by BRF's testing.

David Kingsbury, assistant director of the National Science Foundation and one of the designers of the new government regulatory framework for biotechnology, says that even though the new strain of *S. uvarum* is probably safe and not an environmental hazard, it would come under the highest level of federal scrutiny because it is an intergeneric organism. Kingsbury says this shows that the new federal guidelines are if anything too strict, rather than too lax as some critics have charged. In the case of the new yeast, the Food and Drug Administration (FDA) would probably have initial regulatory authority. Henry Miller, special assistant to the commissioner of the Food and Drug Administration for biotechnology, says the fact that the yeast is a intergeneric organism would have no particular relevance to FDA's regulatory process. FDA's charge is to determine whether it is a food additive, and whether it transforms a product that is already "generally recognized as safe".

Testing outside the United States is hardly a panacea, as the Wistar Institute in Philadelphia, Pennsylvania learned recently. Wistar and the Pan American Health Organization (PAHO) had been conducting a field test of a rabies vaccine using a modified vaccinia virus containing the sequence for an immunogenic protein from the rabies virus. Twenty cows were injected with the modified virus — ten subcutaneously and ten intramuscularly — and housed with twenty unvaccinated animals.

In September, news of the experiment appeared in the Argentine press, stirring a political controversy. That PAHO had not informed the Argentine government that the field trial involved a recombinant DNA organism made matters worse. PAHO has been conducting trials on rabies vaccines at a field station in Azul, 180 miles south of Buenos Aires, and it is unclear whether they had a legal obligation to inform Argentine officials.

Privately, a PAHO official concedes it would have been politic, given the politically sensitive nature of recombinant research, to inform Argentine authorities. Rabies is a significant problem in Argentina, with millions of dollars is cattle lost annually from the disease. Preliminary results from the Azul experiment show that the inoculated animals did show an immune response to rabies, while the uninoculated animals and the four human caretakers did not.

The furore in Argentina is ironic as Wistar associate director Warren Cheston says an Argentine government research laboratory contacted the Wistar Institute in 1984 to ask about conducting field trials with the vaccine. At that time Wistar declined, saying additional laboratory testing was needed.

A team from the Oregon State University in Corvallis had better success testing its modified vaccinia virus. The university announced last week that a field trial for a vaccine for Sindbis virus had been carried out over the past year in New Zealand. Calves, sheep and chickens were vaccinated in the study. None developed disease or transmitted the virus to unvaccinated animals. **Joseph Palca**

India

Move to stop sex-test abortion

Bangalore

CONCERNED over the steady increase in the incidence of female feticide, the government of India is planning legislation to restrict the use of techniques for determining the sex of a fetus. The central health and family welfare ministry in New Delhi is seeking advice from medical experts, social workers, lawyers and women's groups in formulating the legislation. The aim is a comprehensive bill that would drastically limit the practice of amniocentesis and other emerging techniques of prenatal sex-detection.

As it is, the Medical Termination of Pregnancy (MTP) Act of 1971, which stipulates that an abortion can be performed only if there is risk to the life of the pregnant woman or can cause grave injury to her mental or physical well-being, has been ignored by some of the medical fraternity.

For many months, women's groups in Bombay and New Delhi have not only been campaigning against sex-linked abortion but have also been demanding that the authorities provide effective legislation to stop the abuse and to prevent the spread of clinics that exploit the legal loophole.

Mr R.P. Ravindra, a social worker in Bombay, points out that amniocentesis as a tool for sex-determination is almost always followed by abortion if the fetus is female. He says that a study of 8,000 cases of abortion showed that 7,997 of the fetuses were female.

Altering the sex ratio (at present 935 females to 1,000 males) through the abortion of female fetuses could adversely affect the social balance. India has one of the highest maternal mortality rates in the world. Moreover, about 70 per cent of women in India suffer from anaemia and malnutrition, both of which are likely to be aggravated by repeated abortions after sex-determination.

Supporters of the tests claim that the number of unwanted and neglected female children will be reduced and that a scarcity of women will raise the status of women in general. Others believe that the result will be polyandry and an increased incidence of rape and prostitution.

Not much is known about the numbers of sex-test clinics or their operation. Many are run under the guise of maternity homes, clinical laboratories and family health centres. Many are in the industrially and agriculturally advanced states of Maharastra, Punjab, Haryana and Delhi. There are 248 clinics in Maharastra according to the state health department. **Radhakrishna Rao**

Japan

Body light points to health

Tokyo

THE Research and Development Council (RDC) of the Japanese Science and Technology Agency has sufficient confidence in Professor Humio Inaba of Tohoku University to invest about Y15,000 (£70 million) in his research. For Inaba believes that the light people emit may reflect the state of their health.

Inaba's team has found that the blood of patients suffering from diseases such as cancer, diabetes and jaundice gives off much more light as that of healthy people. Smokers' blood "glows" twice as brightly as that of non-smokers, but returns to normal after a day of not smoking.

Although the mechanism of photoemission in each of these cases has still to be determined, peroxidation of lipids through the generation of activated oxygen and free radicals is believed to be involved. Peroxidal lipid reactions are suspected agents in diabetes, liver and lung diseases, arteriosclerosis, ageing and cancer. Inaba believes biophotons will eventually be used for diagnostic and clinical purposes.

The biophoton project is one of the latest additions to Japan's ERATO programme, which was set up in 1981 in a radical attempt to break free from Japan's conservative research system.

ERATO projects run for five years and, with the sole exception of the project leader, the 20 or so participants are all young researchers (under 35) drawn equally from universities, government research institutes and industry. Two or three foreigners are usually included in the team and the research is carried out in independent laboratories uncontaminated by the usual environment of Japan's academic and government research laboratories. Once the theme of the project is chosen, the teams are left to find their own path, sometimes with bizarre consequences.

Inaba, who is attached to Tohoku University's Research Institute of Electrical Communication, became involved in maser research in the late 1950s, during an unsuccessful bid to get a large radiotelescope built in the Tohoku area north of Tokyo. In the 1960s, he turned to the development of high-sensitivity detectors for lasers, and by the end of the decade had devised a laser system for the detection of air pollution using highly sensitive photomultipliers to pick up the scattered light (*Nature* **224**, 57; 1969).

Using Inaba's equipment, biochemists trying to detect the low levels of light expected to be given off during biochemical reactions involving peroxidation were able to detect ultraweak light emissions (of the order of tens of photons per second) from tumours and regenerating livers in mice and rats. But dark noise prevented determination of the spectrum of the emitted light.

Inaba's team, with support from RDC, went on to develop a luminescence analyser in collaboration with Tohoku Electronic Industrial Co. Ltd that can detect less than one photon per second and can handle samples up to the size of a rabbit.

The project will aim at improving this technology to allow measurement of weak biophoton emissions and to bring spatial resolution ot the sub-micron level.

The technology has already found applications in the salad oil, rubber, paint and powdered milk industries, where the degree of oxidative deterioration of the product can be checked in a few minutes by monitoring ultraweak chemiluminescence. But medical applications seem to hold most promise.

David Swinbanks

SERC annual report

THE UK Science and Engineering Research Council (SERC) has asked the government, through the Advisory Board for the Research Councils, for an extra £20 million to make up the shortfall in its budget for 1987–88 due to unfavourable fluctuations of the pound against European currencies. The disclosure was made last week on the publication of SERC's annual report.

Professor E. W. J. Mitchell, chairman of the council, in the introduction to the report, claimed: "Overall the council's task remains the achievement of a sensible balance between curiosity-driven basic research, the seed corn of the future, and the strategic work where application might be anticipated in the medium term. This task is made more difficult within a severely contrained budget, further exacerbated by the wayward behaviour of the exchange rates which in 1985–86 were invariably against us."

Nuclear safety

NRC investigates Seabrook

Boston

THE alleged misuse of drugs and alcohol by construction workers may have compromised the safety of the Seabrook Nuclear Power Plant in Seabrook, New Hampshire, which is due to begin low-power testing at the end of this year. The Nuclear Regulatory Commission (NRC) is now investigating these allegations.

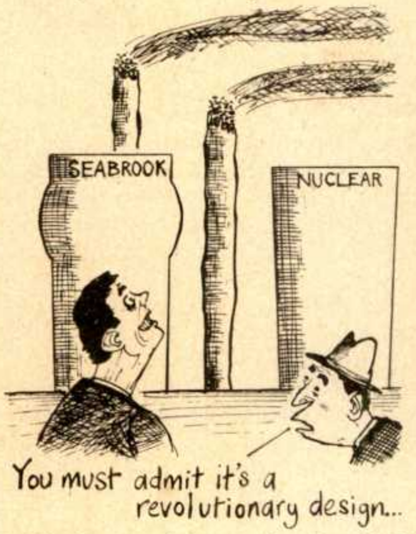
The outcome of the inquiry is likely to affect both the debate about mandatory drug testing and that about existing controls on the safety of nuclear power plants. Drug tests are opposed by those who consider them an infringement of personal liberty.

Several groups, including the energy conservation and power subcommittee of the House of Representatives headed by Congressman Edward J. Markey (Democrat, Massachusetts), have gathered allegations from police, hospital personnel and court employees as well as from the construction workers themselves. The alleged abuses are said to have transformed the town during the ten years of construction.

Former plant workers called Seabrook "a drug addicts' haven". Police have reported finding steel workers "drunk, coming and going" and, according to Dr Gary Lamphere of Exeter Hospital, "it was unusual enough in the early 1980s to see a Seabrook patient without alcohol on his breath to remark on it".

The issue is not whether workers constructing nonvital areas of the nuclear power plant were drunk or high on drugs, says Thomas Elsasser of NRC's Pennsylvania office, but whether "systems essential to safety" have been affected. NRC will judge Seabrook's safety by inspecting documents, examining systems on a sampling basis and monitoring containment and fuel-load tests.

So far, Seabrook has passed all tests: 21,000 hours of inspection by NRC, almost twice that for any other plant in the region, have uncovered no structural reason to believe the plant is unsafe.



You must admit it's a revolutionary design...

But testing after construction is considered unsatisfactory because some parts of the plant are no longer accessible for inspection. NRC may face other obstacles: ti is alleged that some quality control inspections were not completed properly nor documented correctly.

Elizabeth Collins

Queensland and Creationism

SIR—In response to inaccurate statements made by Tony Thulborn (*Nature* **315**, 89; 1985), I am writing to clarify my department's policy on the teaching of the theory of evolution in Queensland State secondary schools.

The Queensland Education Department policy on the teaching of the theory of evolution requires that it be taught (1) as a theory, not as fact; (2) in a balanced manner.

In providing balance, teachers must acknowledge that alternative theories to evolution exist. Some may be supported by scientific evidence; others may not be scientific in nature, but nevertheless based on beliefs deeply held by a significant proportion of the community.

Beyond this, I believe that the question of what constitutes "balance" should be left to the professional judgement of each and every science teacher. I hasten to add that I would be most concerned if a teacher taught the theory of evolution in such a way as to assail the religious beliefs of students. I would be equally concerned if the intent of a science syllabus, in terms of both "content" and "minimum time", were not adhered to.

Sexism and conservation

SIR—The advertisement on the back cover of the 16 October issue of *Nature* shows a young woman clad in only a shell necklace. While past correspondence has discussed the issue of sexism in advertisements in your journal, we want to point out that many gastropods are fished and killed for the explicit purpose of making jewellery because local entrepreneurs have exhausted the dead shells that are washed up on beaches. In certain countries, especially those with tropical shorelines, this practice has reached epidemic proportions and constitutes a major threat to the resident molluscs[1]. Display of material that links (live) girls to (dead) prosobranchs can only damage efforts to conserve sea-shore fauna.

Literary pedantry

SIR—In "What is the scientific literature" (*Nature* **322**, 681; 1986), John Maddox appears to be confusing the medium with the message. Although I, too, decry the poor writing that characterizes many scientific publications, this alone does not drum papers out of the ranks of 'literature'. On the contrary, any scientific paper meets all standard dictionary definitions of 'literature', with the possible exception of the definition that is characterized as *Archaic*, namely, for example, "literary culture" (*Dictionary of the English Language*. Random House, New York, 1968). Maddox is barking up an antique tree.

Problems of Soviet refusniks

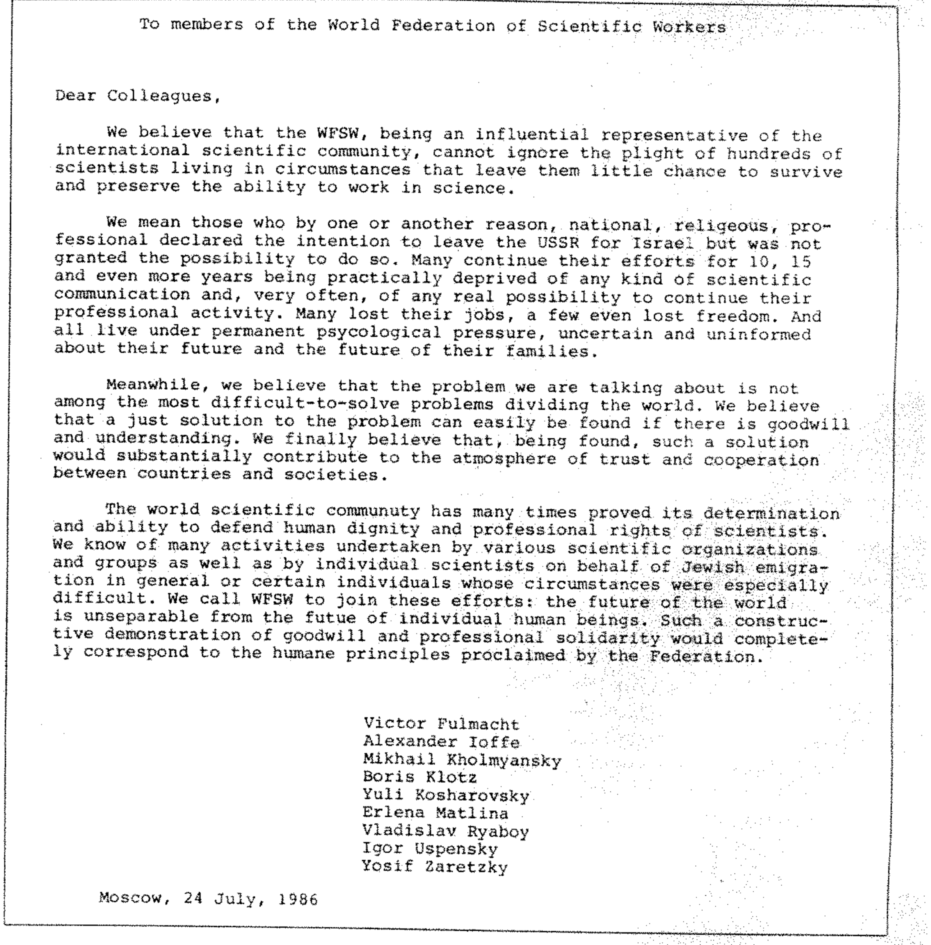
SIR—We beg the courtesy of your columns to address a letter, signed by us and seven of our colleagues, to members of the World Federation of Scientific Workers (WFSW) and its president, Professor Jean-Marie Legay.

We had hoped to hand this letter personally to Professor Legay when he was in Moscow this summer for the General Assembly of WFSW. Indeed, when we telephoned him there he courteously agreed to meet the two of us at his hotel on the morning of 24 July, before the opening ceremony of the assembly. On arrival at the hotel, however, we were denied entry and had to telephone Professor Legay again to explain our difficulty, which he promised to try to deal with. Instead, after some delay, we were forced out of the hotel and away from the entrance area by a group of plain-clothes men who brutally informed us that we had "no reason to meet Legay". Subsequent telephone conversations established Professor Legay's inability to arrange a meeting with us during the remainder of his stay in Moscow.

The text of the letter appears below.

We do not wish to embarrass Professor Legay and WFSW. Indeed, what happened on 24 July was as great a discourtesy to them, in being denied a visit by their invited guests, as it was an affront to us. Instead, what we wish to do is give WFSW, committed as it is to professional solidarity among scientists, the opportunity publicly to press for our professional rights and thus enhance its prestige as an organization dedicated to humane principles.

ALEXANDER IOFFE
BORIS KLOTZ
Moscow, USSR



To members of the World Federation of Scientific Workers

Dear Colleagues,

We believe that the WFSW, being an influential representative of the international scientific community, cannot ignore the plight of hundreds of scientists living in circumstances that leave them little chance to survive and preserve the ability to work in science.

We mean those who by one or another reason, national, religeous, professional declared the intention to leave the USSR for Israel but was not granted the possibility to do so. Many continue their efforts for 10, 15 and even more years being practically deprived of any kind of scientific communication and, very often, of any real possibility to continue their professional activity. Many lost their jobs, a few even lost freedom. And all live under permanent psycological pressure, uncertain and uninformed about their future and the future of their families.

Meanwhile, we believe that the problem we are talking about is not among the most difficult-to-solve problems dividing the world. We believe that a just solution to the problem can easily be found if there is goodwill and understanding. We finally believe that, being found, such a solution would substantially contribute to the atmosphere of trust and cooperation between countries and societies.

The world scientific communuty has many times proved its determination and ability to defend human dignity and professional rights of scientists. We know of many activities undertaken by various scientific organizations and groups as well as by individual scientists on behalf of Jewish emigration in general or certain individuals whose circumstances were especially difficult. We call WFSW to join these efforts: the future of the world is unseparable from the futue of individual human beings. Such a constructive demonstration of goodwill and professional solidarity would completely correspond to the humane principles proclaimed by the Federation.

Mathematics for natural hierarchy

A new way of tackling the statistical problems of spin glasses relies on almost forgotten mathematics, but may have a bearing on problems in biology still unsolved.

How does it so often arise that the solution of newly defined problems hangs on the use of mathematical techniques independently developed, often decades earlier, for quite different purposes or (mathematicians being what they are) for no purpose at all? That question is the starting point for a delightful article in *Reviews of Modern Physics* for July this year in which the concept of "ultrametricity" is offered as an illustration of the principle that essential tools will usually be found lying discarded in the attics of the mathematicians. It goes without saying that the real world is not always as bountiful.

Part of the charm of this winsome piece is that its authors, R. Rammal (from the CNRS low-temperature institute at Grenoble), G. Toulouse (from the École Supérieure de Physique et Chemie Industrielles in Paris) and M.A. Virasoro (of the physics department of the University of Rome), confess that they themselves have only recently stumbled on the notion of ultrametricity, in an article on spin glasses in another physics journal. Like new converts in most fields, they have become enthusiastic proselytizers for the cause (*Rev. Mod. Phys.* **58**, 765; 1986).

Historically, so far as Rammal *et al.* have been able to tell, ultrametricity goes back to 1897, when the German mathematician Kurt Hensel published a recondite piece of algebraic number theory showing, among other things, that an arbitrary integer can always be represented as a sum of ascending powers of some other arbitrary integer, with each term in the series multiplied by a coefficient which may be zero but which is, in any case, less than the base for the ascending power series.

Nowadays, the most familiar illustration of the truth of Hensel's principle is the practice well known to computer buffs of representing decimal integers in binary form, which is merely a way of representing an arbitrary integer as a sum of powers of 2 in which sum the coefficients may be either 0 or 1. The more general statement is that the base of daily arithmetic may be changed from 10 to any other arbitrary base. A further generalization is that rational numbers (with finite, or non-recurring, decimal representation) may always be represented by the sum of powers of some arbitrarily chosen base in which some negative as well as positive powers are included. Rammal *et al.* say that Hensel's work was done in complete isolation, but its practical importance now cannot be gainsaid.

The other mathematical innovation from which ultrametricity has sprung is the formal definition of metric spaces at the turn of the century. For a 'space', or a set of points, to be metric, there must be some function called distance of any pair of points which satisfies the condition that the value of the function is zero when the two points are the same, and that the value is unaltered when any pair of points is interchanged.

Euclidean verities come to mind, together with the euclidean principle that the sum of the distances between one point and a second and between the second and third is greater than the direct distance between the first and the third. This is just another way of saying that, in the euclidean world, the sum of the lengths of two sides of a triangle (say AB plus BC) is greater than the length of the third side (AC). Ultrametricity requires a more stringent principle, that AC should be less than whichever is the greater of AB and BC.

Such a metric world is, of course, an odd world. Rammal *et al.* point to some formal mathematics in the 1940s showing that, with definitions of metric distance satisfying these conditions, any point inside a sphere (defined as the region distant less than some fixed amount from a fixed point) will be itself at the centre of the sphere, and that the only possible triangles will be either equilateral or isosceles (in which case the base must be shorter than the two equal sides). Hensel's work is relevant because it provided one of the first illustrations of how such a metric might be defined.

What relevance can such an odd way of defining distance have to the problems of the real world? Rammal *et al.* start with a phylogenetic tree such as any cladist might construct. The tree implies a hierarchy which, once drawn, implies metric distances between the members at the lowest level, most easily thought of as the length of time since any pair of them diverged from a common ancestor. Then, in the comparison of the distances between three arbitrary extant species, either one pair has more recently evolved from a common ancestor than that evolved from some more distant common ancestor (in which case the triangle is isosceles) or no two of the three species have a common ancestor earlier than the putative common ancestor (in which case the triangle of the distances between them is equilateral in the ultrametric sense).

From this point, it is an easy step to the application of the ultrametric concept to all kinds of intriguing problems in data processing, especially to the use of tree-sorting algorithms. But Rammal and his colleagues are proudest of their novel application of ultrametricity to the problem of spin glasses, the structures (real enough) represented by three-dimensional lattices whose vertices are occupied by spins (think of them as little magnets) and whose energy is the sum of the magnetic interactions between all possible pairs of vertices in the lattice. The problem is that of an Ising lattice in which the simplifying assumption that only nearest neighbours interact is abandoned.

Experimentally, the spin glasses are peculiar materials, especially at low temperatures. Phase transitions occur to states in which the solid material appears to consist of small domains of magnetically ordered spins, but the degree of hysteresis associated with changing external circumstances (such as temperature) is unusual; the materials seem to have a capacity for long-term memory of their previous state. In the decade since the problem of the spin glasses was recognized as such, much has been done by analytical and numerical approximations to show that the low-temperature condition of such a material may be one of a great number of essentially similar configurations that are distinguishable from each other largely by their symmetry. What Rammal *et al.* are able to show is that these configurations are related to each other hierarchically, by means of an ultrametric metric.

That will be an interesting landmark, but will it be an important one? Much depends on whether the authors' speculations turn out to be realistic. They claim, for example, that their line of argument may have a bearing on the travelling salesman problem (how to travel to N cities most economically), the founding conundrum of linear programming. Naturally, they say there is a place for neurobiology in their scheme of things. And since the folding of protein molecules into biologically active materials is a hierarchical process, why not subsume that as well? If they are right, a great many people will be learning a great deal of mathematics they did not previously know existed.

John Maddox

Biological conservation

National park boundaries and ecological realities

David S. Wilcove and Robert M. May

WHEN the United States Congress established in law the boundaries of Yellowstone National Park in 1872, the main motivation was the geology of the area, not the biology. The legislators wanted to create a park of sufficient size to protect the remarkable geothermal features[1] and the boundaries were drawn more or less as a giant rectangle, measuring about 99 by 86 kilometres, and containing well over 900,000 hectares of land. Almost immediately, some people began to wonder whether 900,000 hectares was sufficient to preserve the park's wildlife and natural features. Today, its population of grizzly bears is declining; each winter, elk move out of the park to a much reduced winter range; the state of Montana, fearing the spread of brucellosis to domestic livestock, wants to eliminate any bison that wander off the park; and geothermal energy development outside the park boundaries threatens to disrupt its geysers. A recent study[2] suggests at least seven out of eight national parks in western North America are too small to maintain minimum viable populations of several species found within them.

The lack of congruence between legal and ecological boundaries[2] is common to many parks. In Kenya, the seasonal movements of elephants and other game species take them well outside the boundaries of Amboseli National Park (39,200 hectares). When outside the park, the animals must compete with livestock and contend with poachers. In Costa Rica, three-wattle bellbirds (among other species) annually migrate from the protected montane forest of the Monteverde Reserve into unprotected lowlands. Where park boundaries cross ecological realities, it is usually because the park is too small relative to the space required by particular species, or too small relative to the scale of the natural and man-made disturbances that occur in and around it, such as fires, disease epidemics, insect outbreaks and seasonal or other variations in food supplies.

Territories

Large mammals, like the Yellowstone elk or the Amboseli elephants, need a lot of food and water and must travel far to get it. Their seasonal movements often encompass an area far greater than that of the parks in which they occur and illustrate the particular difficulties posed in the conservation of migratory species. Large predators, which usually occur at low densities, present different problems. As some grizzly bears have home ranges of over 3,000 km^2, Yellowstone National Park by itself simply could not support a viable population of them. The park's grizzly bears are just a part of the larger population that includes those bears in the adjacent national forests.

In an attempt to assess this problem, Newmark[2] recently compared the legal and ecological boundaries of eight national parks in western North America. He defined the ecological ('biotic' in his terminology) boundaries as the area encompassing the entire watershed of a park enlarged, if necessary, to encompass an area of sufficient size to maintain a 'minimum viable population' for the terrestrial non-flying species with the largest home range found within the legal boundaries. Setting the minimum viable population size at 500 — which is probably an underestimate — Newmark found that seven of the eight parks were too small by factors ranging from 6 to 100. Even when the level was set as low as 50, several species of mammals could not be supported in the seven parks.

Re-growing a national park — cow dung with guanacaste seedlings in Costa Rica (*Enterolobium cyclocarpum*). (D.H. Janzen.)

Newmark's findings are not unduly surprising, because none of these parks was set aside expressly to conserve particular mammals. Moreover, parks like Nairobi or Yellowstone (or even Central Park in New York City!) were originally created within a larger area of roughly similar 'wilderness' and so were effectively much larger when they were originally established. Many present-day problems have arisen gradually as settlement and civilization have grown up around such parks. But the magnitude by which these parks today fall short is alarming. Most of the threatened mammals in these western North American parks are top predators, and their disappearance from the parks could trigger further ecological imbalances.

The problem of the scale of natural disturbances is even thornier. How does one go about determining the spatial 'requirements' of a forest fire, a pine beetle infestation, or an epidemic of rinderpest?

Until recently, most natural disturbances were unwelcome inside parks, as they were thought to harm wildlife and scar the landscape. Thus, Yellowstone National Park has a long tradition of suppressing forest fires, even though the lower elevation forests in the Yellowstone region may have burned as frequently as every 20–25 years before the arrival of European settlers[3]. In some areas, aspen stands, an important habitat for some species, are being replaced by conifers, apparently because they are not being rejuvenated by fire. Over the past two decades, park authorites have allowed naturally caused fires in remote areas to burn, provided they do not pose a threat to human life or property.

Disasters

On the other hand, for very rare and localized species or for very small parks, such natural disturbances can be catastrophic. Few conservationists would want to see a fire rage through the world's only stand of Virginia round-leafed birch, however natural such an event might be.

In terms of park design, a further consideration is whether to plan for an 'average' disturbance or a real disaster — the 'fire of the century' or the 'fifty-year flood'. Given the irreversible nature of most land development, it may be wisest to take a rather pessimistic view and to plan for the worst.

There are several ways to make park boundaries more compatible with ecological realities. The simplest solution in the long run is to make the designated parks big enough at the outset. Manu National Park in Peru includes an entire river drainage within its more than 1,600,000 hectares and may be one park that can handle almost any natural disturbance that befalls it. But opportunities to create parks of this magnitude are few and fast disappearing.

A second strategy is to link pre-existing parks, as long recommended by island biogeographers[4-6]. Probably the finest example of this approach is the recent acquisition of La Zona Protectora in Costa Rica by a consortium of conservation organizations, including the Nature Conservancy, the National Park Service of Costa Rica, the National Parks Foundation of Costa Rica, the Organization of Tropical Studies and the World Wildlife Fund. La Zona Protectora is a 7,700-hectare stretch of forest 3–6 kilometres wide that links two important reserves in the country: the upper-elevation Braulio Carillo National Park and the lower-elevation La Selva Biological Station. La Zona Protectora does more than merely increase the total amount of protected land; it attacks the problem of habitat linking the two reserves, it has a much greater additive effect. The combined reserves can support larger populations of many species, and there is now a protected corridor for the approximately 35 species of birds that migrate from the uplands to the lowlands (plus other, less well-known, migratory mammals and insects).

Development

A third strategy is to allow development of the lands surrounding the parks, but to restrict it to those uses and practices that are compatible with conservation goals. Thus, many conservationists in the United States now speak of a greater Yellowstone ecosystem, referring to Yellowstone and Grand Teton national parks (total area 1,022,000 hectares), and parts of the nine national forests (total area 5,747,000 hectares) that encircle them. The management of these national forests is currently the subject of much controversy, as government officials and private citizens debate how activities like logging, mining and grazing should be regulated to avoid harming the flora and fauna of the region.

Another example of an arrangement which is good in principle, but where the actual working is more complicated, occurs in Kenya where the inner 518 km^2 of the Masai Mara Reserve are managed like a park, with no exploitation of the land permitted, whereas in the outer 1,294 km^2 the Masai tribesmen are allowed to graze their cattle[7]. The arrangement sounds fine, but encroachments on the core area are hard to curb. The rules in the Ngorongoro Reserve of Tanzania arguably work better: here the Masai can graze cattle at limited densities anywhere outside the crater, but may only take them into the crater for watering. Despite their problems, restrictive land-use arrangements such as these may be the only means to reconcile the conservation of wide-ranging species with human demands for the land.

Even where development has already harmed much of the land, it is possible to acquire small patches of pristine habitat, along with disturbed areas around it, and then to foster the outward growth of the park into the previously disturbed area. The current scheme to 'grow' a park in dry tropical forest in Costa Rica's Guanacaste Province is an example. The central protected block in Santa Rosa National Park is only about 60 km^2, but the eventual aim is to enlarge the park to several hundred square kilometres by buying low-grade ranch, farm and timber land next to Santa Rosa and on the adjacent Volcan Orosi, and to let the park grow out into it. Only in this way is there likely to be enough area and moist upland refuges to buffer the severely threatened dry forest from normal environmental fluctuations, such as severe droughts and epidemics.

A campaign to buy this land, and create the larger Guanacaste National Park (for a cost of around $10 million) is now underway. If successful, it will demonstrate further that the existing network of parks does not have to be static as long as conservationists continue to come up with imaginative ways to enlarge and improve it. ☐

Robert M. May is Class of 1877 Professor of Zoology at Princeton University, Princeton, New Jersey 08544; David S. Wilcove is at The Wilderness Society, 1400 I Street NW, Washington DC 20005, USA.

Superstrings

In search of a smoking gun

Roberto Peccei

SUPERSTRINGS[1] have squarely split the elementary particle community into believers and sceptics. Superstring theories purport to describe a consistent quantum theory of gravity, unified with that of the other known forces, in which the nature of the matter constituents is also specified. No wonder, therefore, that superstring partisans abound. Unfortunately, all this unification occurs in 10-dimensional space-time, so that real physics can emerge from superstrings only as a result of the spontaneous compactification of the extra six spatial dimensions (see the *News and Views* article by Alvaro De Rújula in *Nature* **320**, 678; 1986). These must curl up into a little ball, torus or other compact shape of radius of the order of 10^{-37} cm. Such scales will never be probed experimentally. Thus, say the sceptics, superstrings will forever remain figments in theorists' fevered imaginations. But a new breed of phenomenologists, superstring phenomenologists, is trying to bridge the gap between these two camps, by examining possible patterns left over from the process of compactification.

Although the energy scale of compactification at around 10^{19} GeV is enormous compared with that probed by present-day experiments (around 10^2 GeV), if superstring theories are correct, not very much is supposed to happen in between. Thus, one can hope to extrapolate smoothly through this energy desert, something which was attempted in earlier work on unifying the strong and electroweak forces into a grand unified theory[2]. Also in superstrings, the usual forces are unified in a large symmetry structure before compactification. For the favoured heterotic superstring[3] this is the group $E_8 \times E_8$, where E_8 is the largest exceptional Lie group. In the process of compactification, however, this large symmetry breaks down to a smaller group. Clearly, for these theories to be sensible, this surviving symmetry group should be that connected with the known low-energy forces, or a small extension thereof.

There is another aspect of compactification which is crucial for four-dimensional physics. Superstrings have supersymmetry, a mathematical property which connects matter particles (half-integer spin fermions such as quarks and leptons like the electron) with the 'fields' that cause forces amongst them (integer-spin gauge bosons such as the photon, causing the electromagnetic force). The gauge bosons are associated with the symmetry group structure of the strings, and to each such boson supersymmetry assigns a half-integer spin partner (a fermion). On compactification, only some of these fermion partners survive. The kind and number of those which do are entirely fixed by the geometry of the compact space. If superstrings are to connect to reality, the surviving states must match fermions we see in four dimensions — quarks and leptons — with perhaps a few extra states yet to be observed.

So far there is no proof that the six unwanted spatial dimensions in superstring theories really can curl up, following the string equations of motion, into a space of a given geometry. In fact, it is not clear that if compactification occurs, there is a unique result. (There may be an infinity of possible worlds, of which ours has the charming property that some of its inhabitants may be able to understand it!) However, it is possible to adduce indirect theoretical evidence[4] that, if this compactification takes place, the compact six-dimensional space is a so-called Calabi–Yau space [5,6] or a generalization of these spaces, known as orbifolds[7]. Proceeding on this assumption, Candelas, Horowitz, Strominger and Witten[4] derived two results which brought superstrings much closer to reality. What they found was that the emerging four-dimensional theory had a symmetry group $E_{6'} \times E_8$ where $E_{6'}$ is either E_6 or one of its subgroups, and that the concomitant four-dimensional fermions occurred only in replicas of a representation of E_6 containing 27 particles. This was good news for superstring fans, as E_6 was already known as a nice grand unified theory group in which the low-energy forces fit well. Furthermore, the 15 quarks and leptons of each family fit perfectly within the 27-dimensional representation of E_6. Matter and forces already known match precisely those emerging from this compactification, with a few extra forces and matter states thrown in for good measure.

The trouble is, one can have too much of a good thing. The simplest Calabi–Yau manifolds end up having enormous numbers (of the order of 100) of repetitions of the 27s of quarks and leptons. They also include forces that cause protons to decay very rapidly, totally at variance with observation. A systematic investigation of more favourable manifolds has been carried out by several groups[8–10] in the past year, imposing reasonable boundary conditions to weed out uninteresting manifolds from the start. One of these conditions is that the resulting group, after compactification, should be so small that none of its gauge bosons can lead directly to rapid proton decay. In effect, this requirement necessitates that the E_6 group be broken at compactification. This obtains in manifolds of sufficiently complex topology so that it is possible for some of the E_6 gauge fields to become trapped in holes in the manifold, leading to a symmetry breakdown[11]. Remarkably, precisely for these kinds of manifolds, the Euler characteristic, which details the number of matter replications, is also small. So two potential problems can be alleviated at the same time.

Two generic results emerge from these analyses[8–10]. First, if all the symmetry breakdown occurs at the compactification scale, the surviving symmetry group contains the known forces plus at least one new force, whose associated gauge boson must have a mass comparable to that of the weak gauge bosons of around 100 GeV. Furthermore, the number of families is limited to three, and exotic states in the 27, besides quarks and leptons, survive at low energy. Second, if there are further stages of symmetry breakdown below the compactification scale, it is possible that the low-energy theory contains just the known forces. All exotic matter is, in this picture, superheavy and experimentally inaccessible; and up to four families of quarks and leptons are permitted.

Clearly the first case is more appealing phenomenologically, because it promises that both new forces and matter are there to be found, providing a 'smoking gun' to test the superstring hypothesis. However, this case is not guaranteed and is in itself not without difficulties. For instance, unless certain couplings of the exotic matter states are absent, protons will again decay rapidly. In this sense, the case with intermediate scale breaking is phenomenologically safer, but it is also almost devoid of remnant signals. This is nicely exemplified by the work of Graham Ross and his collaborators[12] at Oxford, who studied in detail one of the few known three-family Calabi–Yau manifolds. At compactification, this manifold either retains the full E_6 symmetry or is broken down to $SU(3) \times SU(3) \times SU(3)$ or $SU(6) \times U(1)$. None of these patterns is nice. However, Ross and his collaborators[12] argue convincingly (although to my mind not totally compellingly) that a sequence of further breakdowns take place which reduce the $SU(3) \times SU(3) \times SU(3)$ theory to precisely $SU(3) \times SU(2) \times U(1)$ — the gauge theory describing the strong and electroweak interactions. Not only are the forces standard at low energy but so is matter, with the exception of two weakly coupled neutral states. What remains as distinct predictions from the original theory are certain relationships between masses and mixing angles of quarks — predictions which are in fair agreement with experiment. Although this analysis is very nice, this is not much of a smoking gun to convince anyone who is not already an *aficionado* of the reality of superstrings.

In my opinion what will be necessary to sway superstring sceptics (among whom I count myself) is some hard evidence for the existence of superpartners to the low-energy excitations we know. Supersymmetry is, after all, a key feature of superstrings and, even after the Calabi–Yau compactification it remains a good symmetry of the four-dimensional theory. Although the matter fermions divorce themselves from the gauge bosons during compactification, they pick up in the process a set of spin zero partners so that, remarkably, a supersymmetry is retained[4]. Eventually, below the compactification scale this supersymmetry must itself break down. How this happens is the least understood piece of the theory, although it is often suggested that the breakdown is triggered by physics associated with the other E_8 group which is unaffected by the compactification. At any rate, this breakdown of supersymmetry is necessary as it is the seed which allows all 'light' masses to be generated in the theory[13], including the mass M_W of the weak gauge bosons. It is therefore natural, and in fact is required by the internal consistency of the theory, that the mass splitting among superpartners generated by this mechanism also be of the order of M_W.

Superpartners with masses of the order of 100 GeV are in the range of discovery for the forthcoming large accelerators at CERN near Geneva, DESY in Hamburg, Fermilab near Chicago and SLAC in Palo Alto. Their discovery, or that of some other debris of the superstring, would provide us with a first glimpse into extra dimensions. ☐

Data bank for carbohydrate structures

THE need for an international data bank for carbohydrate structures was discussed at a recent workshop, sponsored by the US Department of Energy (Aubern, New York, 7–9 August 1986). Such a facility would provide primary structure information analogous to that obtained from the established amino-acid and nucleotide sequence data banks, which would allow the currently impossible systematic search for structural relationships between the 4,000–5,000 carbohydrate structures so far known.

The computer programs required to organize and store the carbohydrate structural data now exist but are more complex than those used for amino-acid sequences. The complexity results from the combinatorial effects of branching in the carbohydrate chain. Conference participants agreed that structural data would be collected by representatives of the different sub-fields of carbohydrate research and organized centrally at the Complex Carbohydrate Research Center, University of Georgia, under the guidance of its director Dr Peter Albersheim.

The estimated costs for the first year of the project are $200,000. A large contribution (40 per cent) will be made by the US Government and the remainder will come from the twelve other participating countries. Users will pay an annual subscription of $100. This improved access to information will be welcomed by both academic and industrial (for example, pharmaceutical, recombinant DNA, oil) concerns.

An international steering committee was set up to coordinate the growth and funding of the project and the data bank should be in full use within a year. The conclusions of the workshop will be available in about two months from the US Department of Energy.

Celestial mechanics

Arcs around Neptune

Carl D. Murray

PLANETARY rings now form such a menagerie that it had little need for any new attractions — given the diversity of the ring systems of Jupiter, Saturn and Uranus, with their associated dynamical problems. However, the latest addition to the collection is the planet Neptune. Recent occultation results by Covault *et al.*[1] appear to confirm the presence of incomplete rings or 'arcs' around the planet and a new model by Goldreich *et al.*[2] attempts to provide an explanation for a series of puzzling observations.

Since the fortuitous discovery of the rings of Uranus in 1977 when a star was occulted by ring material, Neptune became an obvious target for studies to detect a ring system. A series of peculiar results began with the claimed detection of a small new satellite by Reitsema *et al.*[3] in 1981. Further occultations failed to detect any ring material (that is, a feature observed before immersion — the disappearance of the star behind the planet — and after emersion — its reappearance) until Hubbard *et al.*[4] observed a single feature from more than one site. As the feature was only observed on one side of the planet they believed that they had detected an 'arc' of material some 13–15 km wide at a radial distance of between 63,000 and 69,000 km.

The occultation on 7 June 1985 (Fig. 1) by Covault *et al.*[1] produced a new twist to the story as the star to be occulted was actually a binary. Although no pre-immersion event was observed there was a single post-emersion event but only one of the binary pair was occulted. Using this information the authors calculated that the feature must be discontinuous over several thousand kilometres. There is no independent confirmation of their result but they estimate a width of 8 km and their accurate orbital radius of the feature also lies within the limits set by Hubbard *et al.* There were no further detections during a subsequent occultation on 25 June 1985. Given the number of negative results to date it now appears that the current observations can be explained by at least one narrow, partial ring composed of one or more arcs covering about 10 per cent of the orbital path. How can such as ring system be maintained?

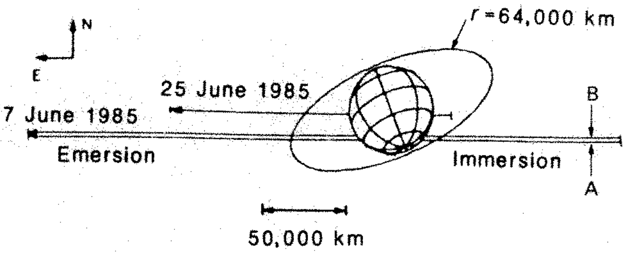

Fig. 1 The apparent paths of stars relative to Neptune for two occultations observed by Covault *et al.*[1] in 1985. Paths A and B refer to the individual stars of the binary pair observed on 7 June. The ellipse shown represents an equatorial radius of 64,000 km, which is a possible location for ring arc occultation events. (Copyright Academic Press.)

Theorists had already considered the dynamical problems posed by arcs in connection with the rings of Uranus. It was originally thought that the outermost ε ring was actually two distinct arcs because occultation features on each side of the planet had different orbital radii. Although it is now known that this is due to the strong ellipticity of the ε ring, the original observations led Dermott and Gold[5] to propose a ring theory involving arcs of material trapped in 'co-rotation' resonances with pairs of Uranian satellites. Resonant phenomena, a common feature in the Solar System, can occur when the periods of two or more objects have a simple ratio and mutual perturbations are enhanced. Lissauer[6] proposed that arcs around Neptune could be explained by the resonant actions of two satellites. The first maintains ring particles in orbits at the classical Lagrange equilibrium points L_4 and L_5 (which precede and trail the satellite by 60°). The second satellite, which lies interior or exterior to the first, provides an additional confinement mechanism to counteract the tendency for the ring to spread due to collisions and other effects.

Goldreich, Tremaine and Borderies have now produced a model for the arc rings of Neptune which relies on the resonant effects of a single satellite in an inclined orbit. The satellite, which may have already been discovered by Reitsema *et al.* in 1981, produces a resonance mechanism which is much more intricate than in previous ring models. They first claim that the arcs lie at one of the strong co-rotation resonances of the satellite. Their location is determined by comparing the orbital periods of a ring particle and the satellite, and also taking into account the longer nodal precession period of the satellite orbit resulting from the oblateness of Neptune. It turns out there will always be an even number of equilibrium positions at the resonant locations and that the ring particles oscillate about each of these positions, forming arcs of material. Goldreich *et al.* then claim that the associated 'Lindblad' resonances involving the orbital periods of the ring particle, the satellite and the pericentre precession period of the ring particle will re-supply the energy lost from the arc through particle collisions. The end result should resemble a series of warped arcs (Fig. 2).

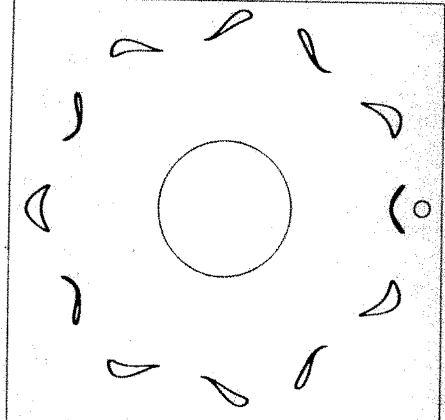

Fig. 2 A possible configuration for ring arcs and a confining satellite around Neptune according to the theory of Goldreich *et al.*[2] Radial variations have been enlarged by a factor of 200. (Copyright American Astronomical Society.)

Given the paucity of hard facts about Neptune's ring system, the model of Goldreich *et al.* seems premature. However, they do make a prediction: the proposed satellite will be found to be in a significantly inclined orbit because otherwise the necessary confining resonances would be too weak. High inclination orbits are the exception rather than the rule for planetary satellites but the most notable exception happens to be Triton, the large satellite of Neptune. The authors speculate that a single event may have produced unusual orbits for all Neptune's satellites.

The study of the dynamics of ring arcs is still in its infancy with many problems still to be tackled. The field will only reach maturity when further observations provide tighter constraints on ring theories. When Voyager 2 reaches Neptune in 1989, the rings of Neptune may be revealed to be even more exotic than we could have imagined. □

Optical physics

Growing expectations from squeezed states of light

Dan Walls

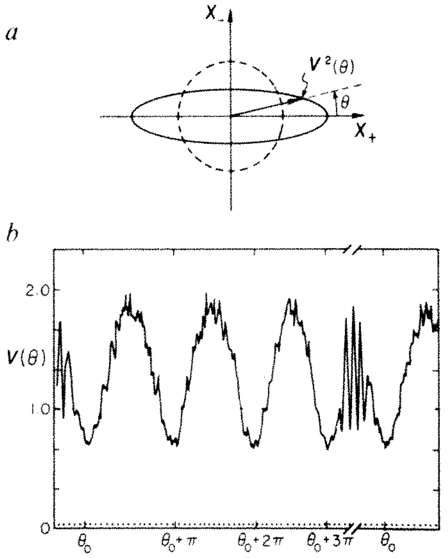
THE past year has seen remarkable progress in the experimental generation of squeezed states of light, which previously were known only to theorists. Squeezed states have the property that the quantum fluctuations in one phase of the wave motion are less than those of the vacuum state of the electromagnetic field, although the fluctuations in the quadrature phase (90° out of phase with the other) compensate by being greater than in the vacuum. In this sense, in one phase squeezed states may beat the quantum limit imposed by the individual nature of the photons, the 'shot noise' of a light beam. There have recently been experimental reports of squeezed states of light generated by four-wave mixing in atomic vapour and optical fibres, and optical parametric oscillation. In the latter, a reduction in quantum fluctuations of more than a factor of two below the vacuum level has been achieved.

The interest in squeezed states of light arises from their possible application in gravitational wave detectors and optical gyroscopes, where they would enhance the sensitivity of interferometric measurements of phase. The reduced fluctuations in one phase offer the possibility of improving the signal-to-noise ratio in quantum-limited optical communications systems. New kinds of experiments in atomic spectroscopy are also feasible. (See my review of the general properties of squeezed states in *Nature* **306**, 141; 1983.)

Squeezed states are generated by nonlinear optical processes involving phase dependent amplification and deamplification of the phases in quadrature. Examples of such processes include four-wave mixing and optical parametric oscillation. The recent experiments examine different variations of these systems.

The first experimental results were reported one year ago by the group of the AT&T Bell Laboratories (Slusher, R.E., Hollberg, L.W., Yurke, B., Mertz, J.C. & Valley, J.F. *Phys. Rev. Lett.* **55**, 2409; 1985) in an experiment in a beam of atomic sodium. The beam is pumped with a coherent dye laser at 589 nm. To achieve a sufficient nonlinear interaction to squeeze the vacuum fluctuations, the laser frequency should be tuned near an atomic resonance. However, as spontaneous emission will destroy the squeezing, the pump laser is detuned from the atomic resonance by 300 atomic linewidths. The vacuum field in an optical cavity noncollinear with the pump laser is squeezed by the four-wave mixing process, and the fields in cavity modes symmetrically displaced from the pump frequency (sidemodes) by 80 atomic linewidths can be detected. This non-degenerate four-wave mixing process ensures the sidemodes are outside the spontaneous emission profile of the atom.

The quantum fluctuations in the output at the two cavity sidemodes are detected by beating with part of the laser which acts as a local oscillator. The local oscillator phase is varied with respect to the sidemodes to detect the quadrature with least fluctuations. The noise reduction observed in this experiment is 17 per cent below the vacuum level, in agreement with theoretical estimates for the parameters of the experiment. But theoretical calculations predict that squeezing should yield a factor of ten reduction in noise at higher pump powers. Another experiment using atomic sodium in a forward geometry in the Doppler broadened atomic vapour regime and no cavity has been performed at the Massachusetts Institute of Technology (Maeda, M.W., Kumar, P. & Shapiro, J.H., personal communications). This experiment has to date achieved a squeezing level of 4 per cent below the vacuum. A further experiment with a sodium atomic beam investigates a new regime for which atomic and cavity timescales are comparable. Initial experiments at the University of Texas in Austin have obtained noise reductions of 13 per cent below the vacuum (Orozco, L.A., Raizen, M.G., Xiao, M. & Kimble, H.J., personal communication).



a, Phase plot of the uncertainties in the quadrature amplitudes of the electric field. The solid line represents the variance $V^2(\theta)$ of the field $X(\theta) = X_+ \cos\theta + X_- \sin\theta$ as a function of θ for a squeezed state; the dashed line is for vacuum fluctuations. *b*, Measurement of the phase dependence of the quantum fluctuations (noise power) in a squeezed state produced by degenerate parametric down conversion. The plot corresponds roughly to the quantity $V(\theta)$ as in *a*. The minima represent a 50 per cent reduction in noise power relative to the vacuum noise level. Note the ordinate is a linear scale in noise voltage. (Courtesy of H.J. Kimble.)

A four-wave mixing experiment but in a completely different type of material, an optical fibre, has been performed by a group at the IBM Laboratory in San José (Shelby, R.M., Levenson, M.D., Perlmutter, S.H., De Voe, R.G. & Walls, D.F. *Phys. Rev. Lett.* **57**, 691; 1986). Light from a krypton ion laser at 647 nm is transmitted through 114 m of glass fibre. Because the laser frequency is far away from any absorption level in the glass fibre, spontaneous emission is not a problem, but Brillouin scattering from acoustic phonons in the fibre introduces excess noise. The fibre is cooled to 4 K with liquid helium to reduce this scattering. The long interaction length in the fibre together with the high intensity of light focused in the fibre compensates for the rather weak optical nonlinearity of glass. Squeezing occurs in continuous pairs of sidemodes symmetrically displaced from the laser frequency. A heterodyne detection scheme is achieved by beating with the original strong laser beam which acts as a local oscillator and can be phase-shifted with respect to the sidebands. This system offers in principle squeezing over a broad bandwidth. However, mainly because of the excess noise from the Brillouin scattering the squeezing observed is limited to 12 per cent.

An experiment using a very different approach to the problem of squeezed state generation has been followed by a group at the University of Texas in Austin (Wu, L.A., Kimble, H.J., Hall, J.L., & Wu, H. *Phys. Rev. Lett.*, in the press) with spectacular success (see figure). The process of parametric down conversion, in which photons of frequency 2*ω* split to produce correlated pairs of photons at the subharmonic frequency *ω*, is used to generate 63 per cent squeezing.

The experiments are perfomed using a degenerate parametric oscillator consisting of a lithium niobate crystal inside a resonant cavity. The cavity is driven by light at the harmonic frequency (0.53 nm) by frequency doubling a Nd-Yag laser (1.06 nm). The down-converted light emerging from the cavity is combined with the original laser emission (at 1.06 nm) using a balanced homodyne detector to observe the squeezing. Although squeezing by more than a factor of two is observed, a quantitative comparison with theory suggests that in fact the intracavity field of the optical parametric oscillator would produce more than ten times squeezing in the absence of losses in the current experiment. Kimble estimates that with improvements in detector efficiencies and cavity parameters the squeezing that can be observed will approach this milestone.

At this level many of the proposed applications of squeezed light look promising. Progress in this area has so far exceeded expectations and we can reasonably expect further exciting developments in the next year. ☐

Plant biochemistry

Discovery of the most abundant inhibitor in the world?

Christine Foyer

The regulation of the activity of the primary enzyme of photosynthetic carbon assimilation, ribulose-1,5-bisphosphate carboxylase, has remained one of the most confusing and elusive areas of plant biochemistry but the recent discovery and identification of an endogenous nocturnal inhibitor, namely 2-carboxy-D-arabinitol-1-phosphate (Gutteridge, S. *et al. Nature* **324,** 274; 1986 and Berry, J. A. *et al. Proc. natn. Acad. Sci. U.S.A.*, in the press), should help resolve discrepancies in our understanding of the modulation of what must be one of the most important enzymes in the biosphere. Together with related observations of a light-dependant activation protein that facilitates optimum enzyme function at ambient levels of carbon dioxide (Salvucci, M.E., Portis, A.R. and Ogren, W.L. *Photosynth. Res.* **7,** 193-201; 1985), this work forms the basis for a new understanding of the overall regulation of carbon assimilation.

Ribulose-1,5-bisphosphate carboxylase was first identified in 1956 but it was not until the mid 1970s that sufficient activity could be achieved *in vitro* to account for the rates of photosynthesis found *in vivo*. Activation of the enzyme requires carbamate formation on a lysine residue of the large subunit followed by reaction with Mg^{2+} ions to form a catalytically active enzyme–CO_2–Mg^{2+} complex but this knowledge provides only a glimpse of the functional capacity and regulation of the enzyme *in vivo*. Full activation of the enzyme *in vitro* requires high levels of carbon dioxide yet it occurs in leaves at ambient CO_2 concentrations. A further problem is that low concentrations of the enzyme activated with high CO_2 and high Mg^{2+} catalyse carboxylation showing distinctly biphasic kinetics with high rates of activity that decline after the first 15–30 seconds of the reaction to a lower steady rate.

A diurnal fluctuation in the specific activity of ribulose-1,5-bisphosphate carboxylase extracted from leaves has been observed in many plant species. Similarly, light activation and dark deactivation of the enzyme have been demonstrated in leaves, leaf protoplasts and isolated chloroplasts. The activation state of ribulose-1,5-bisphosphate carboxylase in leaves can be correlated with irradiance in a manner that cannot be attributed to changes in stromal *p*H and Mg^{2+}. A dark-induced inhibitor of the enzyme may be responsible for this modulation. When leaves are illuminated, photosynthetic carbon fixation shows an induction phase (or lag period) of several minutes before maximum rates are attained. Previous results have suggested that light activation of ribulose-1,5-bisphosphate carboxylase is not an important factor in determining the duration of the induction period but the presence of 2-carboxy-D-arabinitol-1-phosphate adds an extra factor, at least in species where the inhibitor is abundant.

The presence of a dark-induced inhibitor of ribulose-1,5-bisphosphate carboxylase is at once intriguing and puzzling. The degree of activation of the enzyme found in darkness is highly variable and it is not clear why photosynthetic carbon assimilation requires that ribulose-1,5-biophosphate carboxylase is relatively inactive in darkness. Several light-modulated enzymes are present in the pathway whose activity is negligible in the dark. These are activated on illumination long before photosynthesis overcomes the induction period. Now we find that there is another site of inhibition, and nature obviously requires a complete shutdown of the reductive pentose phosphate pathway in darkness.

2-carboxy-D-arabinitol-1-phosphate has so far only been identified in a limited number of species. There may, however be interspecific variation in the metabolism of the inhibitor and also differences in the conditions required for its retention during extraction procedures. We now need to know the biochemical pathways of synthesis and metabolism of this inhibitor and their regulation. Dr A. J. Keys (Rothamsted Experimental Station) has suggested that hamamelose bisphosphate could be a precursor of the inhibitor especially as this sugar-bisphosphate is made and rapidly turned over in the chloroplast. Synthesis and degradation may well be related to irradiance and therefore participate in the regulation of photosynthesis.

Ribulose-1,5-bisphosphate carboxylase has justly been called the most abundant protein in the world. As equimolar amounts of 2-carboxy-D-arabinitol-1-phosphate are required for optimum inhibition, this metabolite must be present in abundance in darkened leaves to be effective. This feature certainly limits any value this compound may have as a potential herbicide. But an understanding of the biochemistry and functional role of this inhibitor may suggest new areas for genetic manipulation of photosynthesis. ☐

100 years ago

I venture to call attention to a simple and effective way of demonstrating the linear expansion of solids when heated, first suggested, I believe, by M. Kapoustine (*Journal de Physique*, December 1883, p. 576). The principle is, to magnify the slight extension of a bar by causing the end of it to roll upon a needle, and thus turn the latter round and move a pointer attached to it through a sensible arc.

A small flat rod of the material to be examine is laid upon two wooden blocks, placed about 25 cm apart. A weight is put upon one end of the rod to keep it from moving; under the other end, at right angles to the length of the rod, is laid a fine sewing-needle, to the eye-end of which a light pointer of straw, about 16 or 20 cm long, is attached by sealing-wax. Behind the pointer (which is painted black) a screen of white cardboard is fixed on the wooden block by drawing pins.

Before the experiment is shown to an audience, it is well to make sure that the needle rolls fairly and freely between the bar and the block. Such precautions, however, are not in the slightest degree necessary for school-work; for there is always one thing which gives the typical boy greater pleasure than to see an experiment succeed, and that is — to see it fail.

Community ecology

Patterns in three dimensions

Paul H. Harvey and John H. Lawton

MUCH of the best in ecology comes from recognizing and correctly interpreting patterns of community structure. Occasionally, the interpretation of one pattern can throw light on another, even in an apparently disparate area of the science. Just such a claim is made by Brown and Maurer on page 248 of this issue[1]. They find that within a group of species that exploit the same class of environmental resources in a similar way, larger-bodied species seem to use up a disproportionate amount of the resources available. They go on to argue that, if their results are correct, a mixture of individual and species selection could provide an explanation for Cope's rule—the finding that members of taxonomic groups typically become larger sized over evolutionary time[2].

Brown and Maurer's analyses concern the relationship between population density and body size in assemblages of birds, fishes, rodents and plants. Larger bodied species are found at lower population densites. Damuth earlier pointed out that population density among African ungulates decreases with approximately the -0.75 power of body size[3]. Because mammalian basal metabolic needs increase with the 0.75 power of body size[4], it seemed to follow that populations of large and small species were using about the same amount of energy. Peters[5] subsequently claimed that the exponents relating population density to increases in body size over a wider range of animal groups are less than -0.75, probably nearer -1.0, indicating that smaller bodied species use more resources. In contrast, the latest analyses by Brown and Maurer suggest that across species exploiting similar resources in a similar way within communities, exponents are appreciably shallower than -0.75. Hence, large species seem to use more energy per population than do small species.

Population density and body size can be considered with a third community variable, the number of species. Each of the three pairs of variables — population density and body size[3-5]; population density and number of species[6-8]; and body size and number of species[9] — are generally considered independently of each other. But knowledge of any two of these relationships automatically provides information about the third (J.H.L. & S.C. Pimm, in preparation). Indeed, if we understand the ecological and evolutionary determinants of any two of the patterns, then the third follows as a necessary consequence. With one exception[9], theories that have been developed to explain each separate relationship in this three-dimensional space have not recognized their interdependence. Even if the energy flow per species is lower in small organisms, because there are almost always more small species than large species in communities[10], the proportion of total community energy flow through small species may nevertheless exceed community energy flow through large species.

The problem then is to explain why energy, or resources in general, are partitioned by many small, or a few large species, and how shares are allocated[10]. Brown and Maurer's observations on population energy use are an important step in this direction. Ecologists need to pay much more attention to establishing reliable empirical relationships between body size, population abundance and number of species in plant and animal communities, as well as to their theoretical interrelationships.

An example comes from the study of species abundance curves that describe the relationship between population density and the number of species. For many years it has been recognized that frequency histograms of the relative abundances (population densities) of the different species exploiting similar resources, when plotted with the abundance on a logarithmic scale, are normally distributed. The distribution is said to be log normal. Futhermore, the number of species in the sample often seems to bear a particular relationship to the variance of the distribution[10]. Log normal distributions with this property are termed 'canonical'. Models of the ways resources might be partitioned among the different species have been produced, the most notable being MacArthur's broken stick[11] and Sugihara's sequential niche division[8] models. The latter actually predicts a species abundance distribution very similar to that observed (it is both log normal and canonical). But such models rest on the assumption that individuals of the different species have identical resource requirements. As Brown and Maurer and others have shown, this assumption does not hold and, furthermore, there is usually an inverse relationship between individual resource requirements and population density. One consequence of the distribution of relative species abundances is that energy may be partitioned among species according to a log normal distribution, but that distribution will not be canonical[12]. It may be that, for once, ecologists have less to explain than they originally thought. ☐

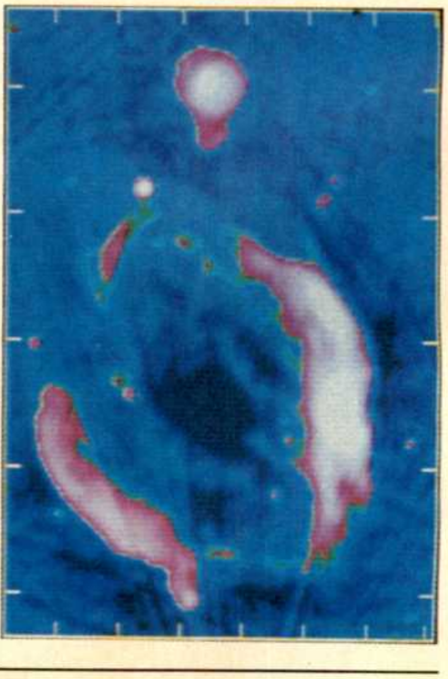
A new nebula

A COLOUR-ENHANCED image of the Circinus X-1 region of the galactic plane obtained with the Sydney University Molonglo Observatory telescope at 843 MHz, with Circinus X-1 itself in the upper region of the image.

Circinus-X-1 may well be one of the more peculiar cosmic objects. It appears to be a binary system, one part of which is so compact it may be a neutron star or a black hole.

As discussed by R.F. Haynes *et al.* on page 233 of this issue, the association of Circinus X-1 with with newly discovered radio nebula is in contrast to most X-ray emitting binary stars. Circinus X-1 is in some ways similar to Cygnus X-1, but no analogous extended radio component has been discovered associated with Cygnus X-1. Comparison is also made with SS433 and the Crab nebula. It is suggested that the nebula results from accumulated energetic particles emitted during flaring activity.



Solar System

How fast does Halley spin?

Philip Campbell

Astonishingly, the rotation rate of the nucleus of comet Halley has suddenly become the focus of intense debate, eight months after the famous spacecraft encounters with the comet. The fact that significant strides have been achieved in the analysis of spacecraft and ground-based photometry and spectroscopy was clear from a recent meeting*. But above all, many participants still seemed to be recovering from the announcement at the previous week's Halley symposium in Heidelberg of the detection of a period in light curves more than three times longer than that hitherto adopted for the nuclear rotation.

The simplest way to investigate cometary rotation, given the acute difficulty in resolving cometary nuclei from Earth, is to seek regular variations in brightness. Because of the vagaries of the allocation of telescope time, there are no light curves available that are continuous since the comet's first detection, making an unbiased Fourier or maximum entropy analysis impractical. One extended collection of data was discussed by M. J. S. Belton (Kitt Peak) but, in reporting a period of 54 hours, he emphasized that he was guided by the selection of possible periods by two previous results — observations from the Japanese spacecraft Suisei of a 2.2-day (53-hour) variability in the ultraviolet intensity of the vast hydrogen cloud surrounding Halley, and an analysis by Z. Sekanina and S. Larson of 1910 dust jet images.

The more sophisticated way to measure the rotation rate of a nucleus is to send three spacecraft to look at it. On 6 March, Vega 1 saw the long axis of the nucleus pointing in a Sunward direction. Three days later, Vega 2 passed Sunward of the nucleus and obtained a broadside image. The two images were consistent with a 480 degree rotation about a spin axis perpendicular both to the long axis of the nucleus and to the orbital plane, as would accord with a 53-hour period. More recently the Giotto and Vega images were considered in combination by both imaging teams who independently arrived at a 53-hour period.

For much of the Heidelberg meeting the cometary scientists had been happy with this rotatory paradigm. But the harmony was broken somewhat when R. L. Millis and co-workers from the Lowell Observatory announced the detection of a strong 7.4-day period in ground-based photometric observations using emission bands such as C_2, CN and OH (*Nature*, in the press). The light curves, measured in March and April this year, reveal a characteristic double-peaked structure which Millis identified as that produced by active regions entering sunlight once every rotation period.

No-one questions the reality of the 7.4-day period in the data — it has now been reported by other observers. For example M. F. A'Hearn *et al.* (Maryland), following their unexpected discovery of the existence of spiral jets of CN thought to be the photodissociation product of dust emissions (*Nature*, in the press), have found that a 7.4-day period and not a 2.2-day period satisfies the relative orientations of the jets at different times. In contrast, B. Smith (Arizona) of the Vega imaging team is adamant that the orientations of the nucleus at the three spacecraft encounters cannot accommodate such a period. It is all the more intriguing, therefore, that another member of the Vega team, J. L. Bertaux (Service d'Aeronomie, Verrières-le-Buisson) is less categorical. Nevertheless it does seem that proponents of the 7.4-day rotation period, if they are to conform to the imaging constraints, will have to appeal to a rotation axis more inclined to the long axis of the nucleus and a more complicated nuclear geometry than has hitherto been thought necessary.

As it happens there is still scope for further image enhancement. If the 2.2-day rotation period survives such scrutiny, what can be made of the 7.4-day light curve variations? Their regularity points to some dynamical origin and that most widely assumed seems to be a free wobble (a motion not maintained by a torque) equivalent to the terrestrial Chandler wobble of the Earth, though much closer to the rotation rate of the comet than is the rate of terrestial Chandler wobble to the rotation rate of the Earth. At Heidelberg, K. Wilhelm of the Max Planck Institute, Lindau, who had analysed the motion of an appropriate-sized ellipsoid, reported that a wobble period of about six days was not unreasonable and was consistent with the spacecraft images.

Despite the fact that such a wobble could not be observed directly from outside the cometary coma, its behaviour, if manifested in photometric light curves, could yield useful information about the interior of the nucleus. The wobble would presumably be excited by the jet activity as the comet passed through the vicinity of perihelion. Over the subsequent orbital period, as shown by Wilhelm, it should be damped out by internal friction. But in Paris, M. Festou (Observatoire de Besançon) presented an amalgamation of all available photometric data taken between January 1984 and February 1985, showing that a 7.4-day period was significant throughout. As J. Lissauer (U. C. Santa Barbara) emphasized, interpreting this as a wobble would imply a significant amplitude near the very onset of emissions from the nuclei, in turn implying small internal damping and a comparatively rigid nuclear interior.

Although such detailed studies of the behaviour of Halley have proved unexpectedly engrossing — and may remain so for some time — more wide-ranging questions were also addressed in Paris, relating in particular to the vast but putative Oort cloud of comets from which Halley is thought to have originated. The darkness of cometary nuclei, emphasized by spacecraft images of Halley, combined with the new findings of the shape and degree of activity of the nucleus, allowed P. Weissman (Jet Propulsion Laboratory) to generalize and estimate afresh the total mass of the cloud, increasing it over a thousandfold above Oort's original estimate of a tenth of an Earth mass or less. This could imply that more comets have collided with Earth than hitherto thought, also strengthening the idea that an early generation of comet-like objects may have delivered the stuff from which the atmospheres and oceans to be found on the terrestrial planets are derived.

The perturbations of the Oort cloud thought to produce long-period comets have traditionally been ascribed to random encounters with passing stars. Recent theoretical work, however, indicates that ever-present galactic tidal forces should also play a significant role. A. H. Delseume and M. Patmiou (Toledo) plotting the aphelia of 152 selected long-period comets in galactic coordinates, reported 'zones of avoidance' at the Galactic poles and equator, consistent with a tidal effect.

In reviewing the progress in the analysis of spacecraft data, E. Grun (Max Planck Institute, Heidelberg) described surprising results from the PUMA dust impact mass analysers on the Vega spacecraft. Small particles ($< 1\ \mu m$) have been found with relative abundances of C, N and O very similar to those in the Sun and much higher than those found in carbonaceous chondritic meteorites. Similarly, gaseous isotope ratios measured from spacecraft and from the ground are consistent with solar abundances. Though the spacecraft results are still preliminary, all the signs are that — as has always been hoped — comets contain by far the most primitive and pristine material to be found in the Solar System. □

Yeast genetics

Genetic control mechanisms: transcriptional twisting

Ian W Dawes

YEAST geneticists and molecular biologists have long been advocating yeast as a model eukaryotic organism as well as an organism for exploitation by the biotechnologist Reservations about the usefulness of such a model are based largely on the relatively uncomplicated nature of the yeast life cycle and partly on differences from higher eukaryotes in the mitotic and meiotic processes At a recent meeting*, however, it became clear that much progress has been made in the study of those cellular processes for which yeast is ideally suited One example of such a process is the regulation of transcription

Now that important regulatory sequences have been identified upstream of several genes in yeast, the search is on in earnest to find proteins binding to these sequences and to determine how this binding leads to specific control as well as initiation of transcription With regard to the nature of the upstream sequences concerned with positive control, the seven genes for allantoin degradation (*DAL1* to *DAL5, DAL7, DUR1,2*) which are all under the control of the *DAL81* gene, contain two types of consensus region (T G Cooper, University of Tennessee, Memphis) For efficient constitutive expression, Cooper proposed an upstream expression sequence (UES) which is found in front of all the above genes at least once For the highly regulated *DAL4, DAL7* and *DUR1,2* genes there is a second sequence, an upstream modulation sequence (UMS) present in multiple copies, which is involved directly in the inducibility of these genes For the less inducible genes (*DAL1* and *DAL2*) there are fewer UMS elements, and these exhibit only limited homology with the consensus region For the constitutive genes (*DAL3* and *DAL5*) there is no UMS

The distinction between expression and regulation sequences is not radically different from what has been reported for other genes that have been examined (and maybe soon the terminology will be agreed), but the nice point of this work is the extent to which the correlation between control sequences and inducibility holds for a group of genes under one type of control

It also illustrates the extent to which UMS and UES sites can be fairly scattered around in the 5′ upstream region of a naturally regulated system For negative control of the *CAR1* gene, Cooper's group has found a 13-base pair sequence (an upstream repression sequence, URS) that is necessary for repression, and which can control *CYC1* expression if cloned upstream or downstream of the upstream activating sequence (UAS) elements This sequence is present in the 5′ flanking regions of more than a dozen genes of widely diverse functions, including nitrogen catabolism, protein synthesis and glycolysis, and it may be part of a more global regulatory system, or possibly a generic sequence associated with a repressor binding site as it does show some homology with the phage λ repressor binding site

Several points have emerged about proteins binding at the UAS elements The DNA-binding proteins that have been sequenced have short domains for DNA binding relative to the overall length of the molecules (for example, the amino-terminal 74 residues from 881 for the product of the regulatory *GAL4* gene (G Gill, Biochemistry and Molecular Biology, Harvard University) and 60 carboxy-terminal residues from 282 for the *GCN4* gene product conferring general amino-acid regulation (K Struhl, Harvard Medical School) These DNA-binding regions show the helix-turn-helix motif of prokaryotic repressors Other regions of these control proteins are necessary for the activation of transcription, thus fusions of the carboxy-terminal end of the *GAL4* gene product and the *Escherichia coli lexA* protein will bind to *lexA* promoters and initiate transcription in a heterologous yeast system (Gill) The elegant work from Struhl's laboratory with the *GCN4* gene product shows that in addition to the short DNA binding site at the carboxy terminus, this protein has a central and even shorter (19-residue) acidic domain needed for the activation function There are similar acidic regions in other yeast regulatory proteins and in the HMG proteins thought to be important in regulation of higher cell development (Struhl) Deletions between the DNA-binding and acidic domains do not abolish the activity of the protein *in vivo*

The presence of a single DNA-binding regulatory protein at the UAS is not sufficient for control — other proteins are involved This has been found for the upstream control of the two cytochrome *c* genes *CYC1* and *CYC7* (L Guarente, Massachusetts Institute of Technology) *CYC1* expression is regulated by haem and glucose from two elements, *UAS1* and *UAS2* Dissection of the 73-base pair *UAS1* region reveals one protein (plus) binding the one region, and two others (HAP1 and RC2) to another How do the proteins binding at these UAS sites affect the initiation of transcription which can be located from 250 to 1,000 or more base pairs downstream from the UAS site? Rudi Planta (Vrije Universiteit, Amsterdam) described the proponents of various hypotheses as being either "twisters, sliders, oozers or loopers" (see Ptashne, M *Nature* **322,** 697–701, 1986) Gill, a confirmed looper, suggested for the *GAL1* gene that up to four molecules of the *GAL4* product bind at UAS_G and interact with other proteins binding nearer the start of transcription, thereby introducing a loop in the DNA and bringing the UAS and the transcription start site into juxtaposition

With all the current discussion of whether the human genome should be completely mapped and sequenced, and who will pay for the exercise, it is interesting to see how far similar exercises have progressed in an organism with only a fraction of the haploid DNA content M Olson (Washington University School of Medicine, St Louis) reported on progress in the task of restriction-mapping the entire yeast genome at the 2-kilobase level By using 'bottom up' screening of about 5,000 λ inserts for overlaps, about 600 local maps have been identified, which should reduce to about 200 on a second pass through the restriction data The other approach of 'top down' mapping using OFAGE electrophoresis to separate the 16 yeast chromosomes and map them individually with the rare cutting restriction enzymes *Not*I and *Sfi*I, generating about 200-kilobase fragments, is also well under way, with more than half of the 55 *Sfi*I fragments mapped, and complete maps for eight of the chromosomes One of the early goals of this work should soon be realized the production of an ordered set of λ clones to allow precise location of a newly cloned gene in a single hybridization experiment The organization of chromosome 1 (the smallest chromosome, in which 250 kilobases can encode only about 100 genes) is the furthest advanced Kaback and colleagues (New Jersey Medical School, Newark) have mapped 160 kilobases of almost contiguous DNA representing 70 per cent of the chromosome, and have also studied transcription from genes previously undetected by mutation

Any report of a meeting of the size and interest of this one is bound to be fragmentary and selective Fortunately, for the first time the complete abstracts of a meeting in this series are available in published form as a supplement to the journal *Yeast* □

Fingers and helices

SIR—On several occasions the interaction between *Xenopus* transcription factor IIIA (TFIIIA) and 5S RNA genes has been discussed in *Nature*, News and Views[1-3] TFIIIA is a good example of the so-called finger proteins[4], eukaryotic regulatory proteins which contain variable numbers of a characteristic tendemly repeating motif of about 30 amino acids[5,6] It is currently thought that these sequence repeats represent small nucleic acid binding domains, each folded about a tetrahedrally coordinated zinc ion The coordination is provided by appropriate side chain atoms from fully conserved histidines and cysteines This had led to a model in which TFIIIA is essentially a 'string of beads' that zigzags along one side of a nucleic acid double helix in an extended fashion[7]

Our observation[5] of the repeating motif in TFIIIA, which has unfortunately been overlooked by most authors, allowed us to make a reasonable prediction of the average secondary structure of the repeat We have now extended the secondary structure analysis to include all the finger sequences known to us (Table 1) The prediction technique[8] involves calculation of smoothed plots for each of the three conformational preference parameters (α-helix, β-strand and turn) for individual sequence repeats The smoothed curves are then averaged over all the repeats The most strongly predicted region spans alignment positions 17–23 (Table 1) where the mean smoothed helix preference varies from 1 1 to 1 15 Given that 1 0 indicates a neutral preference and that 1 4 is the largest preference, the helical prediction over the 39 repeats is clear

†The consensus for an alignment position is given if 19 or more of the 39 residues are conserved according to the groups (ST), (PG), (KR), (QNED), (MC), (HFYW) and (AIVL)

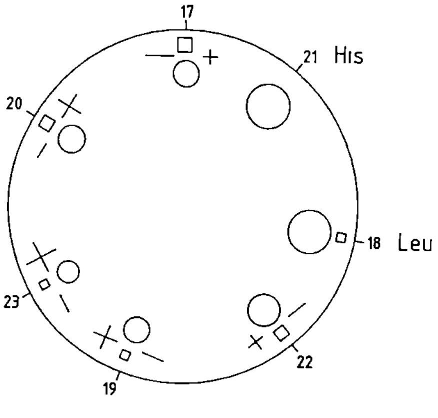

Fig 1 A 'helical' wheel representation of the predicted α-helical region in the 'finger' sequences The wheel is numbered according to the alignment in Table 1 The positions of the strongly conserved Leu 18 and His 21 are shown The symbols used to illustrate the amphipathic nature of the α-helix are (○) for hydrophobic residues (IALVMCHYWF), (+) for basic amino acids (KR), (−) for acidic/polar residues (QEDN), and (□) for (PSTG) The size of the symbols are proportional to the amino acid composition at each alignment position

An α-helical wheel representation[9] of the span (Fig 1) shows an obvious hydrophobic/hydrophilic sidedness, typical of helices observed in many three-dimensional protein structures One of the conserved histidines suggested for zinc coordination and a strongly conserved leucine are located on the hydrophobic side of the predicted α-helix This span may act as the principal finger region for interaction with nucleic acid

Two preliminary spectroscopic observations in this laboratory support the helical suggestion Circular dichroism curves of the TFIIIA protein as analysed by the method of Provencher[10] indicate the presence of 10–15 per cent α-helix A fluorescence quenching analysis of the 7S particle shows an approximate 30 per cent increase in intensity upon digestion of the RNA with ribonucleases or its salt-induced dissociation We interpret this result as evidence for changes in the environments of the two tryptophan residues (W28 and W177) in TFIIIA which are just at the amino-terminal side of the predicted α-helix Apparently their degree of exposure and structural flexibility is altered considerably upon binding to nucleic acid

Data in graphs and tables

SIR—After reading Paolini's discussion on enzyme units and how to express them[1], my attention was drawn to a similar ambiguity in the literature, concerning the units in which data are expressed when shown in tables or plotted in graphical form

Basic mathematics tells us that the value of a physical quantity is equal to the product of a numerical value and a unit

physical quantity = numerical value × unit

According to the convention followed by the Royal Society[2], the expression used to define the numerical values of a physical quantity plotted on a graph (or the one which is placed at the head of a column of numerical values of a physical quantity in a table) should be a pure number, and the axis on the graph (or the head of the table) should be labelled with physical quantity/unit — for example, radioactivity/(d p m $\times 10^3$) — thus, making the numbers in graphs and tables dimensionless If this convention is not followed, that is, if the numerical values in graphs and tables are considered to be dimensional, then the axis on graphs and the heads of tables should be labelled with the appropriate units (d p m $\times 10^3$, and not d p m $\times 10^{-3}$ as is often the case)

Figure 1 summarizes several ways of expressing data in graphical form In this figure, molar was the chosen unit because conventional prefixes like nano, micro, milli, and so on, are very commonly used, which is not the case with d p m (for which Bq is now the recommended unit)

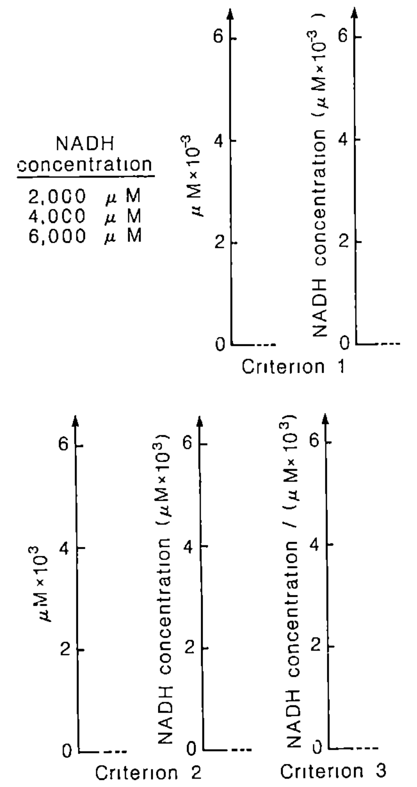

Fig. 1 Hypothetical experimental data showing common criteria for graphical presentation

and some other units Despite the method approved by the Royal Society (criterion 3) being mathematically the most precise and elegant, it is difficult to envisage its general use particularly outside the scientific community (in, for example, newspapers and television) In many (most?) biochemical papers, criterion 1 seems to be followed and even in well established books it is easy to find inconsistent usage here for example, in ref 3 criterion 1 is used in fig IV-29 but fig IX-2 uses criterion 2 Use of criterion 1 may be prone to ambiguous interpretation as shown in Fig 1 — with data in thousands of μM (indeed mM), we end up with the axis labelled μM × 10^{-3} when this criterion is followed (not in fact mM, but nM[1])

Although in virtually all cases it is easy to recognise which method has been used (and this may explain why several methods coexist), the indiscriminate use of different ways of labelling graphs and tables does not contribute to the clarity with which scientific knowledge must be presented In this respect, I would rule out criterion 1 because it is the most ambiguous

Silver from Chernobyl

SIR—I beg to differ with R H Flowers (*Nature* **323** 208, 1986) concerning the origin of ^{110m}Ag in fallout from Chernobyl

It is easily calculated that at most 400 grams of the fission product ^{109}Ag had been produced in the reactor core of Chernobyl-4 up to the moment of the accident On the other hand the reactor was equipped with about 200 in-core neutron detectors of the self-powered type with emitters composed of silver These emitters are up to 2 5 metres per detector and, in all, contain many kilograms of natural silver, about 48 per cent of which is ^{109}Ag

Therefore the ^{110m}Ag which has also been detected in significant amounts in the Netherlands, is indeed an activation product but almost entirely originates from molten detectors

Chernobyl fallout in Debrecen, Hungary

SIR—Since 1952, total beta activity of fallout in precipitation has been measured in Debrecen without interruption[1,2] The precipitation is collected daily by a PVC funnel (40 cm diameter) and evaporated into standardized glass cups, where total beta activity is measured by an end window Geiger-Muller counter

On 29 April, 2 7 mm (340 cm^3) of rain was collected, but previous activity levels were unchanged However, the shower of rain on 1 May (0 48 mm) resulted in 1,450 Bq m^{-2} initial total beta activity (Fig 1) The next rainfall, on 9 May, was collected and processed in two parts (2 5 mm before noon and 3 1 mm afterwards) The initial activity of the first part was 2,500 Bq m^{-2} and that of the second part was only 160 Bq m^{-2}, which is impressive proof of the rapidity of change in tropospheric radioactivity and shows that the main mechanism of fallout deposition is rainfall The specific activities of these three samples were 2,645, 980 and 46 Bq l^{-1} respectively

We have identified the radioisotopes by the γ-ray spectra of the samples using a 100 cm^3 Ge (Li) detector surrounded by a 5 cm lead shield The isotopic composition of the fallout in the precipitations before noon on 1 May and 9 May proved to be the same, though the intensity ratios of short half-life radioisotopes were different

The residual activity on the later date was that of the isotopes ^{103}Ru, ^{95}Zr, ^{95}Nb, ^{106}Ru, ^{106}Rh and ^{134} ^{137}Cs

In all, after 10 May the total beta activity level was less than in the first three samples, and did not significantly exceed, those of past years after 25 May

Birth of a separate science

Peter Harman

Intellectual Mastery of Nature: Theoretical Physics from Ohm to Einstein. Vol. 1 The Torch of Mathematics 1800–1870; Vol. 2 The Now Mighty Theoretical Physics 1870–1925.
By Christa Jungnickel and Russell McCormmach. *University of Chicago Press: 1986. Vol. 1 pp. 350, $55, £46.75; Vol. 2 pp. 434, $65, £55.25.*

IN AN autobiographical sketch, written in 1891 towards the end of his exemplary career, Hermann von Helmholtz explained that he had sought "intellectual mastery of nature" in pursuing a career in science. Originally working principally in physiology, in physiological optics and acoustics, he had also made substantial contributions to physics. Helmholtz's classic memoir *On the Conservation of Force* (1847) provided a mathematical formulation of the principle of the conservation of energy, one of the grand unifying principles of nineteenth-century physics; and papers on hydrodynamics and electrodynamics confirmed his reputation as one of the greatest mathematical physicists of the day. Relinquishing physiology, he moved to Berlin in 1870 as professor of physics; he found the subject to be "the true basis of all proper science".

It was in theoretical physics, above all, that German scientists found "science as a vocation", and it was through the "torch of mathematics" (in Ohm's telling phrase) that they sought to realize their intellectual mastery of nature. At the beginning of the nineteenth century, German universities provided no more than elementary physics lectures for students who would go on to professional studies in medicine, law or theology. The main argument for educational reform was the hoped-for regeneration of the cultural and political reputation of the German states; its tool was the incorporation of research into the universities. The effect was the creation of scientific institutes and increasing specialization within the natural sciences. In their superbly written and exhaustively researched study, Jungnickel and McCormmach find the division of physics into theoretical and experimental specialities to be the distinctive feature of German physics in the nineteenth century.

Drawing on a rich supply of archival materials from universities and state bureaucracies, together with a thorough sampling of the physicists' scientific work, Jungnickel and McCormmach present a comprehensive and convincing picture of physics in nineteenth-century Germany. Some very complex science is described with economy and precision, but without undue technicality, and the authors have written an integrated narrative in which the scientific work of the physicists is portrayed in its institutional setting. The collaboration has proved remarkably successful, with the authors' interests (Jungnickel's more in institutional history, McCormmach's more in intellectual history) being effectively blended. In his *Night Thoughts of a Classical Physicist* (Harvard University Press, 1982) McCormmach has already presented a glimpse of the materials here meticulously documented, in the form of a fictional reconstruction of the life of a German physicist active from the latter part of the nineteenth century.

BBC Hulton Picture Library

Hermann von Helmholtz, "classical master".

Physical theory, or "natural philosophy", had long been a subject of study, yet only by the beginning of the nineteenth century was the term "physics" being used in the modern sense to denote a study of mechanics, optics and electricity which employed mathematical and experimental methodology. At that time physicists strongly emphasized quantification and the search for mathematical laws, and sought a unified science of physics based on the concept of energy and the programme of mechanical explanation. In seeking to give an integrated account of the scientific work in its institutional setting, Jungnickel and McCormmach concentrate on the physicists' work as an organizing principle. Research and teaching were carried out in institutes within the universities, and the book is structured around the development and proliferation of these institutes.

The pattern of development was remarkable. Early in the nineteenth century German physics was struggling to distance itself from the prevalent "nature philosophy". University professors and authors of texts tried to combat Hegel's contempt for the natural sciences. Around 1830 physics began to become established as an academic discipline, especially at Göttingen and the new university of Berlin. Gauss's collaboration with Wilhelm Weber in Earth-magnetic observations, Ohm's mathematical theory of electric currents and Franz Neumann's work on optics and electricity all contributed to establishing a coherent corpus of German physics. Much of the inspiration for mathematical physics came from France, the work of Laplace, Poisson, Fresnel and Fourier providing notable exemplars, but by the 1840s a German tradition was emerging. Helmholtz's unification of physics in terms of the conservation of energy drew on work by Gauss, Weber, Ohm and Neumann. German work on electricity was especially notable; in the 1840s, Weber, Kirchhoff and Neumann published substantial memoirs. As a tyro electrician in 1854, James Clerk Maxwell felt the need to study these works, the "views of heavy German writers". Weber's electrodynamics, Helmholtz's energy physics, Clausius's work on thermodynamics and the "mechanical" theory of heat, all strove for unifying concepts by which the foundations of physics could be established.

The subject prospered even though physics institutes suffered from shortage of space and resources, and after 1870 the development of theoretical physics as a study distinct from experimental physics owed much to the new teaching needs which faced physics institutes. The requirement for a second teaching post within individual universities led to the creation of "extraordinary" professors in theoretical physics. These positions were planned as transitional appointments for young scientists who were expected to move on to an "ordinary" professorship in experimental physics and to the control of a physics institute. But eventually, following the example of Berlin, institutes of theoretical physics came to be established with theoretical physics being understood as that part of the subject concerned with the precise measurement of physical constants as well as with mathematical physics. Specialization was considered acceptable if the twin sides of the subject were kept in balance: as Helmholtz urged,

> without mathematical physics, experimental physics is a very narrowly bounded science and affords little insight into the course of physical

> phenomena, while . . . mathematical physics without experimental physics, would likewise be a rather lame and unfruitful science.

This attitude shaped Helmholtz's evaluations of candidates for university positions. Jungnickel and McCormmach consider Max Planck as the first true specialist in theoretical physics (in the sense that his career developed entirely in the subject). Yet Planck was considered by Helmholtz to be an "excellent acquisition" in replacing Kirchhoff as Berlin's theoretical physicist in 1889; Planck was a "splendid man" because his work was closely based on the experiments of others, on the interpretation and development of experimental measurements.

The main intellectual influence shaping German physics after 1870 was the work of James Clerk Maxwell. Helmholtz's influential treatment of electrodynamics and evaluation of the unique importance of Maxwell's electromagnetic theory of light encouraged the research of Heinrich Hertz, first under Helmholtz's direction at Berlin and then at Karlsruhe, which ultimately led to his decisive experimental test in favour of Maxwell's theory in 1888. As a visitor to Helmholtz's institute anxious to gain experience of experimental work, Ludwig Boltzmann undertook experiments (on dielectric constants) which bore on the confirmation of Maxwell's theory. In his research on the kinetic theory of gases and the entropy concept, Boltzmann extended Maxwell's law of the distribution of velocities among the molecules of gas, creating statistical thermodynamics. And in Leiden, Lorentz developed the "electron" theory which blended elements from German electrodynamics with Maxwell's theory of the electromagnetic field. The theoretical initiatives of Lorentz and Boltzmann, both much sought-after in German institutes of theoretical physics (Lorentz remaining in Leiden, but Boltzmann seeking to assuage his depression by moving to and fro between Graz, Vienna, Leipzig and Munich), encouraged German physicists to look to Maxwell's electromagnetic theory and molecular mechanics for their inspiration.

By the end of the century German physics, especially theoretical physics, manifested classical coherence and also innovatory thrust. The lectures of the classical masters Helmholtz and Kirchhoff summarized and codified the achievements of the past. The endeavours of Planck and Wien, debating the rationale of energetic and electromagnetic foundations for physics, opened the door to the new physics of quanta and relativity of the twentieth century, itself a creation of German theoretical physicists yet shaped by the problems which were perceived to flow from Maxwell's work. Planck came to exercise a formative influence, succeeding Kirchhoff in Berlin, and on Helmholtz's death becoming the advisor for theoretical physics for the *Annalen der Physik*. His research on blackbody radiation led him to introduce the quantum of energy, although he remained cautious about its implications. Nevertheless he was an early and influential supporter of Einstein's special theory of relativity.

Jungnickel and McCormmach conclude their account with an overview of the developments which arguably constitute the high point of German physics, the creation of the general relativity and quantum theories in the first quarter of the twentieth century. The authors emphasize the confluence of intellectual and institutional developments. Einstein came to the Prussian Academy and to Berlin in 1913 as the outstanding theoretical specialist, and soon delivered the "scientific eggs" in his general theory of relativity. The emerging generation of theoretical physicists, including Pauli and Heisenberg, received their education at the hands of men who had pursued careers as specialist mathematical physicists, Sommerfeld at Munich and Born at Göttingen. If classical physics had achieved its apotheosis in the lectures of Helmholtz and Kirchhoff, the new generation could build creatively on the shoulders of giants. The "now mighty theoretical physics", as Wilhelm Wien described it in 1915, had attained status as a "separate science". ☐

Naked appreciation

P.W. Hawkes

Principles of Charged Particle Acceleration. By Stanley Humphries Jr. *Wiley: 1986. Pp.573. $65.95, £63.15.*

THE difference between electron optics and the optics of charged particle acceleration is not unlike that between nudity and nakedness. It is possible to write a book on electron optics that sets out from a few premises and provides an elegant abstract description of the behaviour of electrons in the lenses, accelerating structures and analysers of which many instruments are composed. The typical example is P.A. Sturrock's *Static and Dynamic Electron Optics* (Cambridge University Press, 1955), in which it is not too fanciful to recognize the austerity of the classical nude.

In the optics of charged particle acceleration, on the other hand, the blemishes and homely imperfections of mere nakedness cannot be overlooked: many different kinds of particle may be present in the beam, the current density may be so high that the particles jostle one another in a way that renders the fundamental equations unmanageable, instabilities may set in and, in the great accelerators of recent years, even the irregularities of the underlying terrain cannot be neglected.

Stanley Humphries is well aware of the complexity of his subject matter and steers a middle course that accelerator physicists and engineers will be able to follow easily. Like Sir Thomas Browne, he believes that "where there is an obscurity too deep for our reason, 'tis good to sit down with a description, periphrasis or adumbration". He opens with concise accounts of particle dynamics in electric and magnetic fields, field calculation and materials properties. The next three chapters are concerned with lenses: round lenses, quadrupoles and sectors. Their effects on particle beams are first examined in terms of the elementary lens properties, after which the notions of acceptance and matching are introduced. The last of these chapters explains the transfer matrix formalism. Humphries does not go far into these optical matters, but this merely emphasizes that he has written a book on acceleration and has included only the necessary minimum about them.

Apart from a single chapter on the difficult theme of phase dynamics, the rest of the book offers a detailed and knowledgeable account of the various types of accelerator. Electrostatic accelerators and pulsed high-voltage, linear-induction accelerators, betatrons, radiofrequency accelerators and, finally, cyclotrons and synchrotrons: each of these is accorded a separate chapter, as are the resonant cavities and waveguides employed. Not only are the modes of action of the various machines clearly described, but the book is also a rich hoard of down-to-earth engineering detail that will make it used and appreciated far beyond the introductory course on the physics of charged particle acceleration that inspired it.

Humphries has brought together and successfully organized a mass of material in the first large single text to be devoted to his subject since *Linear Accelerators*, a multi-author work edited by P.M. Lapostolle and A. Septier and published by North-Holland in 1970. I suspect that many readers will need to go elsewhere to delve into the subjects of the earlier chapters in more detail, but they will surely forgive the author for preferring to save his space for the accelerators themselves. Altogether, this is an impressive and consummately useful volume. ☐

How mistakes are made

Leslie E. Orgel

Accuracy in Molecular Processes: Its Control and Relevance to Living Systems. Edited by T. B. L. Kirkwood, R. F. Rosenberger and D. J. Galas. *Chapman & Hall: 1986. Pp. 398. £48.50, $110.*

The frequency of errors in the transmission of DNA sequence information from one generation to the next can be as low as one per 10^8–10^{10} bases copied. Transcription and translation have substantially higher error rates, but are still far more chemospecific than comparable non-enzymatic processes. The measurement of error rates, the study of the enzymatic mechanisms that maintain them at low levels and the investigation of the cumulative effect of errors on the health of the organisms that harbour them have become the subject matter of a subspeciality of biochemistry. This subspeciality is the subject of the present multi-author volume. The "accuracy" of methylation, restriction, splicing and other post-synthetic modifications of proteins and nucleic acids is not discussed.

The empirical data on the accuracy of DNA replication, and the classic mechanism of error correction by exonuclease activity during replication are discussed in a chapter by Goodman and Branscomb. The role of DNA repair in maintaining the integrity of the genetic material is covered by Sedgwick. The accuracy of RNA synthesis is discussed by Anderson and Menninger.

Protein synthesis is dealt with in three chapters. Fersht covers the charging of tRNA and deals in detail with editing pathways that remove "incorrect" amino acids hydrolytically from charged tRNAs. Buckingham and Grosjean review the literature on the accuracy of mRNA–tRNA recognition and show that recognition depends on many factors beyond the complementary pairing between codon and anticodon triplets. Kurland and Gallant deal with the role of the ribosome in controlling the accuracy of protein synthesis.

In addition to these empirically based reviews, there are other, mainly theoretical contributions on such topics as the kinetic cost of accuracy (Ehrenberg, Kurland and Blomberg), selection for optimal accuracy (Kirkwood and Holliday) and the effects of errors on the integrity of genetic information transfer (Rosenberger and Kirkwood). A chapter on probabilistic thinking about enzyme kinetics by J. Ninio provides a number of qualitative insights that are not readily derived from the differential equations of traditional chemical kinetics.

This volume is a valuable addition to the literature of biochemistry because it brings together reviews of all of the important aspects of the "accuracy" problem. It is not always easy going — the introductory material is highly compressed and requires very careful reading, as do many of the more theoretical sections. But the determined reader will be rewarded with an excellent overview of an important but little-known area of biology. □

Solar systems

A.K. Turner

Physics, Technology and Use of Photovoltaics. By R.J. Van Overstraeten and R.P. Mertens. *Adam Hilger: 1986. Pp. 278. £35, $70.*

The potential of photovoltaic solar-energy conversion as a renewable energy source is widely recognized. Photovoltaic power is already finding remote-site application in telecommunications, navigation aids and water pumping, for example, predominantly using crystalline silicon-cell technology. Calculators and watches with amorphous silicon and cadmium telluride solar cells are also now common. Surprisingly, there are few good general texts on the subject, which makes Van Overstraeten and Mertens's contribution all the more valuable.

The book begins with a comprehensive account of the background to the physics of solar cells, made particularly interesting by the inclusion of a thorough description of the mechanisms which can account for loss of solar-cell efficiency. The theory is also developed separately for monocrystalline and polycrystalline silicon, amorphous silicon, gallium arsenide and other thin-film photovoltaic cells.

The method of manufacturing crystalline silicon photovoltaic modules is covered in great detail, from silicon purification and crystal growth, through cell fabrication, to the assembly of finished modules. In contrast, the section on thin-film technology is rather brief, with only a limited discussion of the various options. On the practical side, there are sections on measurement of the efficiency of light conversion of cells and modules, and their ability to withstand different environmental conditions, on cell interconnection in modules and on important factors in the design of photovoltaic systems for particular applications.

The book concludes with a summary of existing applications of photovoltaic systems which serves well to demonstrate the current dominance of crystalline silicon. This may well justify the authors' rather scant treatment of the emerging, potentially cheap, thin-film technologies such as amorphous silicon, cadmium telluride and copper indium diselenide cells which have yet to find large-scale commercial use beyond consumer applications.

Well written and logically structured, the book is easy to follow, and provides both a good text for the student and a useful reference work for the researcher. It describes the physics, technology and uses of photovoltaics for an audience anxiously awaiting a breakthrough in the availability of a low-cost, renewable energy source — we must hope that we don't have to wait too long. □

The many stages of carcinogenesis

D.G. Harnden

Introduction to the Cellular and Molecular Biology of Cancer. Edited by L.M. Franks and N. Teich. *Oxford University Press: 1986. Pp.458. Hbk £30, $59; pbk £15, $32.50.*

WILL Shakespeare started it: "One man in his time plays many parts". Since then analogies have run rampant. Now Beverly Griffin sees the seven ages of DNA — she does it well, and optimistically forecasts that in the seventh age the intricacies of the normal cell will be unravelled and lead to an understanding of cancer.

Perhaps I should try it — the seven ages of making a cancer textbook. First, the student, perhaps not "mewling and puking", but certainly confused by a subject such as oncology, where the range of disciplines is wide and information has to be picked up from many teachers and often from a variety of courses. Next, the teacher dedicated to a coordinated oncology course. Anyone who has tried, knows the problems. How can you even begin on DNA manipulation unless there is a firm grounding in DNA structure? Yet if you do not take much as read, there is not time to get from DNA to cancer therapy. And then, the brave editor, suggesting that the course should be converted into a book — the students are proferred more detail and time can be devoted to discussions. So distinguished experts send in their contributions, which somehow must be woven into an accurate and readable whole.

Much to their credit, Franks and Teich have succeeded to a large degree where others have totally failed. Their book will be of great value, not only to students but to anyone who wants a broad view of current knowledge of the scientific basis of cancer. The authors are indeed distinguished, the coverage is excellent and the prose very readable.

The groundwork is well laid by Franks himself, while chapters on metastasis and epidemiology ensure that the behaviour of cancer and the scale of the problem are well understood. But the heart of the book deals with carcinogenesis, cellular and molecular processes, and the nature of the cancer cell. The theme of stages set by Griffin recurs throughout the book. Multistage carcinogenesis is universally agreed, but each author sets these stages rather differently. For example, Adam sees radiation carcinogenesis in stages from the physical (10^{-12} to 10^{-18} seconds) to the cell and tissue stage which lasts months or years. Even growth factors operate in stages, and Waterfield spells them out from the external signal to the nuclear response. Though the details of clinical cancer are beyond the scope of the work, the link to clinical problems is handled briefly but clearly.

This book is therefore at about stage four in its evolution; very good but not yet excellent. The authors, not too "jealous in honour", invite comment for its future improvement. Perhaps they could look to the order of the chapters. For example, why does Greaves's excellent chapter on the biology of leukaemia come so early? It makes no concessions to the uninformed and confronts complex ideas about cell lineages, maturation arrest and expression of cell-surface molecules. The editors should also consider the difficult problem of how much background to fill in; some of the contributors expect sophistication of their readers, while others go back to first principles.

So onward to stage five. After that, stage six will be superb, "full of wise saws and modern instances". But what of stage seven? Let me predict — sans page, sans printed word, sans everything, except perhaps a computer terminal. □

Death on the Nile

D. M. Dixon

Science in Egyptology: Proceedings of the 'Science in Egyptology' Symposia. Edited by A. Rosalie David. *Manchester University Press/Longwood Press: 1986. Pp.525 £45, $77.50.*

IN THE course of excavations in Egypt and Nubia, carried out over several decades about the turn of the century, thousands of mummified and naturally preserved human bodies were recovered, ranging in date from pre-Dynastic times to the Christian period. Unfortunately, because of lack of specialist personnel on the staff of expeditions, the opportunities presented by this material were not fully exploited. With a few notable exceptions, excavators often simply selected for retention and later examination at home those bones which appeared to them to exhibit some abnormality or other point of interest. In general, the remains that did find their way to museums were for the most part neglected for years, during which specimens deteriorated and labels became detached.

Co-operation on any scale between Egyptology, science and medicine was slow in coming, and it was not until the mid-1960s that practical steps were taken to remedy the situation. The appearance of *Diseases in Antiquity*, edited by D. Brothwell and A.T. Sandison, and published in 1967 by Charles C. Thomas, marked a turning-point, although not all of the papers were concerned with Egypt. Shortly afterwards the work of Chiarelli and his colleagues at Turin, and the foundation of the Paleopathology Association in 1973 through the efforts of Aidan and Eve Cockburn, gave added impetus to interdisciplinary research on life in the ancient Nile Valley.

The Manchester Symposia of 1979 and 1984 have continued and expanded that work, the scope of the latter gathering being widened to include the discussion of techniques applied to pottery and other antiquities. This volume contains a printed record of all the papers presented in 1984, together with a selection of those from 1979. Inevitably, the contributions vary considerably in value, but there is much of interest here. Among the most promising developments is the extraction and cloning in bacteria of DNA from mummified tissue, discussed by S. Pääbo, and the possibilities this offers of determining, among other questions, the genetic relationships between individuals and populations. This is clearly a matter of some importance to scholars grappling, for example, with the complexities of the history of Egypt during the latter part of the Eighteenth Dynasty.

An obstacle in the way of examining mummies has hitherto been the understandable reluctance of museum curators to allow the use of techniques which involve the total or partial destruction of specimens in their care. The application of endoscopy, described by E. Tapp and his colleagues, has changed things almost overnight. It has also permitted the taking of biopsies from such areas as the lungs and the confirmation of diagnoses based on radiological examination.

While the range of techniques discussed in this book is impressive, and augurs well for research on the lives of ancient peoples generally, a note of caution is necessary. There is still a long way to go before Egyptologists can turn to their medical and scientific colleagues with the reasonable expectation of receiving satisfactory answers to their problems. In this regard Renate Germer's closing paper, "Problems of Science in Egyptology" makes salutary reading. As she reminds us, much of the information obtained through the use of methods discussed at the Symposia is at present of limited help to Egyptologists because "a great deal of basic research has yet to be done to determine the applicability of the scientific methods themselves". □

D. M. Dixon is a Lecturer in the Department of Egyptology, University College London, Gower Street, London WC1E 6BT, UK.

Glittering prizes for research support

David F Horrobin

Could public support for research be cheapened, and made more productive, by following the eighteenth-century precedent of the British government's prize for a means of measuring longitude?

THE crisis in British universities, the shortages of research funds and the insistent demands that science should serve the economic needs of the nation which supports it, ought to require a fundamental rethinking of our approach to the financing of science I see much evidence of panicky tinkering by both the scientific community and the government, but few indications of radical thought

We should perhaps consider what may be the first example of parliamentary funding of research, which is also one of the most successful Because it is such an excellent precedent, those in power might take it seriously The hero is Mr John Harrison, born in 1693 the son of a poor Yorkshire carpenter, a self-educated clockmaker and the toast of Neil Armstrong at a twentieth century 10 Downing Street dinner

Petition

In a petition to the British Parliament on 25 March 1714, Captains of Her Majesty's Ships, Merchants of London and Commanders of Merchant Men demanded a solution to the problem of measuring longitude at sea Failure was causing innumerable navigational disasters with the loss of ships, men, goods and battles The government, wisely, chose not to throw money at the problem by supporting research by experts who, by definition, had failed to solve it Instead, they arrived at an astonishing proposal a prize of £10,000 was offered for a method that would reliably measure longitude to within 1°, £15,000 for a method accurate to within 40′, and £20,000 for a method accurate to within 0 5° In 1714 those sums were truly astronomical Anyone winning the prize would become not merely comfortable but genuinely rich

The result was an outburst of private research on longitude The problem and the prize were known to everyone They are mentioned in Swift's *Gulliver's Travels* and a Hogarth cartoon shows a lunatic obsessed with them Theoretically, it was known that one way to solve the problem was to make a timepiece so accurate that it would tell the time at Greenwich even after many weeks at sea, much buffeting and drastic changes in temperature Comparison of that time with local time would then allow an accurate calculation of longitude

None of the experts believed that a timepiece could be so accurate An array of bizarre and complex proposals was put forward by the Fellows of the Royal Society and their friends, but all failed Only poor, provincial, self-taught John Harrison believed that a clock could be made to the required standards His story is well known his production of increasingly reliable, robust and accurate chronometers, their objective success in Royal Navy trials, his denigration by the eminent gentlemen of the Royal Society, the attempts by the Society's experts to deny him the prize legitimately won, the anger of the King when he heard about these academic machinations and Harrison's final triumph with grant of the full £20,000 at the age of 80 But the lessons to be drawn from this remarkable story are as valid now as they were in the eighteenth century

- The announcement of a cash award sufficiently large to make the winner enormously wealthy will generate a phenomenal outpouring of research directed to the solution of practical problems Such research will be privately financed and will cost the donor nothing but the cost of the award
- Such an award will lead to unprecedented cross-fertilization of fields of endeavour If the prize is large enough, scientists whose speciality may appear remote from the problem will be stimulated to think about it
- The definition of success must be crystal clear, practical and open to verification by non-experts The solution need not be brilliant or sophisticated, nor need it meet with the intellectual approval of experts The only condition is that it must work
- There must be no limitation on the categories of people allowed to succeed The challenge must be open to non-experts and to the sons of poor carpenters

Prizes

The government should decide what problems it wants solving In my field of medicine, obvious problems whose solutions would save a great deal of money include schizophrenia, eczema, multiple sclerosis and Alzheimer's disease People from other fields should be able to produce long and comparable lists Economists could then work out what each particular problem costs the nation, and a prize could be offered for a practical approach which would either eliminate the problem or reduce the cost of solution The prize should be the value of the savings made during one full year

Some of the prizes might turn out to be very large indeed, tens or even hundreds of millions of pounds Even greater amounts would be possible if, say, the European Community, the United States and other countries acted together, as they might well do if the scheme cost little or nothing The prize should be given tax free to the individual, company or group producing an answer

The advantages of the scheme would be many, but include

- The cost of initiating the scheme would be trivial After the first year, a successful solution would save millions
- Researchers of all kinds would be encouraged but not forced to work on practical problems They would also be encouraged to extend their range of expertise
- There would be large inflows of private venture capital into research as individuals, companies and others chose to support research directed towards the solution of problems attracting the larger prizes
- There would probably be rapid progress in basic science Many now suffer from the illusion that basic discoveries always precede practical research Historical evidence suggests that the traffic is just as frequently in the other direction We have forgotten the story of Pasteur Brilliant people devoting themselves to practical problems, such as the spoiling of wine or dying silkworms, may end up by discovering new fundamental principles
- The enterprise would be cash-generating rather than cash-consuming Governments would be delighted with science instead of looking at it with a jaundiced eye
- Last, but by no means least, the huge cash prizes would put money into the hands of the most practically creative members of society The money would certainly be spent in interesting ways, on further research, on enterprising investment or even on innovative techniques of personal consumption

The idea would cost almost nothing to put into operation It would rejuvenate science and transform attitudes to science It should be given a try □

Uncertainties in the smoke source term for 'nuclear winter' studies

Joyce E. Penner

Lawrence Livermore National Laboratory, University of California, Livermore, California 94550, USA

Climate models have shown that the effects on climate of a major nuclear exchange depend on the quantity and optical properties of the smoke that is dispersed into the global atmosphere. Published estimates for each of the factors necessary to determine the smoke optical depth yield a wide range of values, which allows the prediction of either comparatively minor effects on climate or massive effects.

THE potential effects on climate of large amounts of smoke injected into the atmosphere following a major nuclear exchange have been widely analysed[1-4] Although simplifications and uncertainties still exist in the application of climate models to calculate the effects of smoke, many of the simplifications that had to be made in the first studies have now been corrected These improved climate models have shown that the effects of smoke on climate depend on the quantity and optical properties of the smoke that is generated and dispersed into the global atmosphere

The amount of smoke and its optical properties can be summarized by the average optical depth that would result if the smoke were dispersed throughout half the Northern Hemisphere If the extinction optical depth $\bar{\tau}_e$ is taken as the sum of the scattering and absorption optical depths, it may be calculated from $\bar{\tau}_e = (k_s + k_a)S/A$, where k_s and k_a are the scattering and absorption cross sections of the smoke (in $m^2\,g^{-1}$), S is the amount of smoke (in g) and A is the area blocked by the smoke cloud (taken as half the area in the Northern Hemisphere, or $1\ 28 \times 10^{14}\ m^2$) The quantity of smoke may be calculated from $S = \varepsilon F(1 - f_r)$, where ε is the emission factor of smoke (g smoke per g of fuel burned), F is the amount of fuel burned, and f_r is the fraction of smoke removed by precipitation in the convection column above the fires and in the first few days after the war, during which the smoke is presumed to spread out to global scales The original 'baseline' analysis of Turco *et al*[2] resulted in an estimate for $\bar{\tau}_e$ of ~6 for smoke produced in urban fires Their smoke had a single scattering albedo of ~0 5, so that $\bar{\tau}_a = k_a S/A$ was ~3 0 Consideration of the additional smoke from wildlands fires, long-term fires and dust from surface bursts increased the estimate for $\bar{\tau}_e$ to ~8 (Turco *et al*[2] spread their smoke over the entire Northern Hemisphere, so that their published optical depths differ from these by a factor of 2) All subsequent analyses have similarly implied 'best estimates' for $\bar{\tau}_e$ that were substantially greater than 1 Here I review the estimates for the various factors which contribute to $\bar{\tau}_e$ and $\bar{\tau}_a$, to obtain reasonable bounds on the range of magnitudes consistent with current knowledge This range encompasses values that may be associated with major climatic effects if a large fraction of the available urban combustible load is burned On the other hand, within the bounds set by current analysis, comparatively minor effects are also possible, especially if the targeting of weapons avoids refineries and other large storage facilities that contain petroleum or other fossil fuels I then recommend several areas for research that could lead to more certain estimates of the effects of such a war

Amount of fuel burned in urban fires

As pointed out in ref 5, several methods have been adopted for estimating the amount of fuel that might burn in urban fires These methods are not mutually consistent In the method adopted by Turco *et al*[2], which yields the highest fuel estimate, the amount of fuel burned in urban fires is determined from the product $F = \mathrm{FL} \times f_b \times A_i \times \mathrm{SF}$ where FL is the average areal fuel load within the burned-out region (in $g\ m^{-2}$), f_b is the fraction of fuel that is consumed by fire within the area that burns, A_i is the area that is initially ignited by the fireball (in m^2) and SF is the average areal spread factor for the fires

An overestimate by this method may be caused by at least two factors Most often, no account is taken of the overlap of burned areas when detonations take place near one another Secondly, the entire ignited area and its radially expanded spread is assumed to coincide exactly with the urban fuel bed and with the average fuel load FL This assumption may be seriously in error, for example, for targets such as airports that generally reside on the outer edges of cities It is often argued that these effects are mitigated by the choice of a 'conservative' value for A_i—that is, one that corresponds to the area that would be ignited by a thermal fluence of $20\ cal\ cm^{-2}$, rather than the area associated with a thermal fluence of $7\text{-}10\ cal\ cm^{-2}$, which is considered sufficient to ignite at least the lighter fuel elements such as paper and twigs In Nagasaki, where the presence of hills restricted the fire ignition area[6], the actual area burned ($A_i \times \mathrm{SF}$) corresponded to the area which would have received a thermal fluence of $20\ cal\ cm^{-2}$, whereas in Hiroshima, the area burned corresponded to the area which received only $7\ cal\ cm^{-2}$ It would therefore seem that the area corresponding to $20\ cal\ cm^{-2}$ is indeed 'conservative', if $\mathrm{SF} = 1$

It is not known, however, whether the two effects mentioned above (overlap and improper average values for FL) would indeed be balanced by an underestimate for $A_i \times \mathrm{SF}$ Several lines of inquiry suggest that the overestimate may be significantly larger than the factor of 2 underestimate made by using a fluence area corresponding to 20 rather than $7\text{-}10\ cal\ cm^{-2}$ The analysis in ref 7, which consisted of a large attack on cities, suggests that consideration of overlap may reduce the value of A_i by as

Table 1 Average combustible fuel load in cities

Authors	Fuel load ($kg\ m^{-2}$)
Turco *et al*[2]	
Baseline case	33 5*
100-Mtonne, city centre	200 0
Crutzen *et al*[10]	40 0†
NRC[3]	40 0
Reitter *et al*[8]	
Detroit, centre	34 5
Detroit/San Jose, suburbs	10 2

* Average of $100\ kg\ m^{-2}$ in 'city centres' and $30\ kg\ m^{-2}$ in suburbs
† This estimate was not used in the final analysis of ref 10 (see text)

much as a factor of 4 Also, overlap of ignition areas may reduce fire spread, if intense firestorms are generated which create inflowing winds On the other hand, with more intense fires, the fuel may burn more thoroughly, increasing f_b

The value used for the average fuel load can be checked by an analysis of some of the fire spread modelling results of Reitter *et al*[8] (see also Appendix 3A of ref 4) All previous studies of the amount of fuel that might burn have assumed average values for FL of ~40 kg m^{-2} (see Table 1), although values from 10 to 400 kg m^{-2} are quoted as possible[3] Table 1 also shows the average areal fuel loads within the ignited areas corresponding to a 1-Mtonne nuclear explosion over the centre of Detroit and several 1- and 0 5-Mtonne bursts over detonation points above suburban Detroit and central San Jose, as taken from Reitter *et al*[8] These data imply that values closer to 10 kg m^{-2} should be used for most urban and suburban areas Furthermore, if the fuel loads for Detroit are correct, values for FL of ~40 kg m^{-2} are appropriate only for weapons directed at the centres of large cities The average fuel loads from Reitter *et al* consider only those areas occupied by buildings, so that these average values do not account for any decrease in FL due to targeting on the fringes of cities or near lakes or parks which would have lower average fuel loads The fuel loads were developed from surveys taken in the late 1960s, but recent analyses of fuel loads in San Jose[9] are similar to the average fuel load used by Reitter *et al* for that city The Detroit fuel loads used by Reitter *et al* seem surprisingly low, but result from averaging the fuel loads in the centre of that city (which range up to 160 kg m^{-2} over small areas) with values near 10 kg m^{-2} in outlying regions Note that Detroit has a population of >4 million There are only 39 urban centres in the world with a population of >3 million, and only 80 cities in the NATO and Warsaw Pact countries with populations of >1 million The oft-quoted "100-Mtonne central city" model of Turco *et al*[2], assumed values for FL of 200 kg m^{-2} in 100 cities these loads appear to be overestimated by a factor of 5 Of course, one must check whether European cities or cities in the eastern United States contain much higher fuel loads than those quoted here for Detroit But it seems highly probable that the estimates for FL used previously are too large, especially in view of the analysis of total fuel load outlined below Crutzen *et al*[10] also rejected this method in favour of the inventory approach outlined below Finally, note that the above analysis for FL assumed targets which were entirely contained within the urbanized areas occupied by buildings Consideration of actual target locations, some of which will occur on the fringes of cities and some of which will fall near lakes or other low-fuel-density areas, will further reduce the estimate for FL

Significant further reduction of the uncertainties using this approach requires a detailed analysis on a city-by-city basis, with consideration of specific target locations, fuel loads and overlap of fire areas Here we consider an alternative approach, in which total combustibles are estimated directly and then a fraction is assumed to be ignited and burned

The total inventory of combustibles has been estimated by Crutzen *et al*[10] and by Bing[5], using different methodologies Pittock *et al*[4] also estimated inventories, but as ref 4 is primarily a review of ref 10, they will not be separately quoted here Crutzen *et al*[10] used production figures for various raw materials and estimates of their lifetimes to obtain estimates for the total abundance of cellulosic materials, polymeric materials and asphalt Bing[5], on the other hand, gathered data from surveys of fuel loads in various types of structures and their contents for the United States, and extrapolated these data to Europe and the Soviet Union The two sets of published figures are not directly comparable because Crutzen *et al* estimate the amount of celluosic and polymeric materials in the developed world, whereas Bing's estimates refer only to the NATO and Warsaw Pact countries Crutzen *et al* and Bing also separately estimate the amount of petroleum available to burn, including petroleum stored as primary stocks and as secondary stocks The figures of Crutzen *et al* refer to the amount of petroleum stored globally, wheras Bing's numbers again refer only to that fraction contained within the NATO and Warsaw Pact countries In order to consider similar models, I have reduced the inventories published by Crutzen *et al* for the developed world by the ratio of the population of the NATO and Warsaw Pact countries to that of the developed world Their estimates for petroleum were similarly reduced by the ratio of consumption rates in NATO and Warsaw Pact countries to that of the world As shown in Table 2, Crutzen *et al*'s inventory still implies 2 5 times more cellulosic material than does Bing's Remarkably, as the methodologies were different, the estimates for petroleum-derived materials are similar The total amount of fuel in primary stocks of petroleum is fairly well known and the two estimates are comparable The amount of fuel in secondary stocks of petroleum is less well known Two different sources of data have led to a difference of a factor of 2-4 for fuel in this category, as shown in Table 2

The methodologies used in these two studies have obvious difficulties, and it is not clear which method is more appropriate Note, however, that the totals for cellulosic and polymeric materials assumed by Crutzen *et al*[10] are not entirely consistent with the fuel load estimates derived from Reitter *et al*[8] For example, we may use the average areal fuel load for urban and suburban areas from ref 8, together with the total urban area in cities with population greater than 2,500 in the United States, 135,000 km^2, to arrive at a combustible load for the United States of 1,350 Tg Consideration of 50 city centres with fuel loads similar to that of Detroit might increase this total to 2,000 Tg This number is close to the value derived by Bing[5] for the United States (2,119 Tg), and thus lends confidence to his estimates On the other hand, when Crutzen's numbers for the developed world are scaled by the ratio of population in the United States to that in the developed world (0 225) we arrive at 4,400 Tg, which is at least twice as large as the estimate above In the analysis below, both numbers will be used to estimate the range of optical depths that are possible, given current uncertainties

Table 2 Inventory of total available combustibles in NATO and Warsaw Pact countries (Tg)

Authors	Cellulosic materials	Primary petroleum stocks	Secondary petroleum stocks	Polymeric materials
Crutzen *et al*[10]	16,500*	462†	198-462†	574*
Bing[5]	6,444	480	100	753

* Reduced from the estimate for the 'developed world' in ref 10 by the ratio of populations, 0 87 (G Bing, personal communication)

† Reduced from the estimate for the whole world in refs 4 and 10 by the ratio of consumption rates in NATO and Warsaw Pact countries to that of the world, 0 66

Table 2 summarizes the inventories of combustibles in NATO and Warsaw Pact countries, derived by these two methodologies To allow consideration of the range of smoke absorption properties from various fuel types, Table 2 divides the inventories into cellulosic fuels, petroleum-derived fuels and liquid fossil fuels This last category has been subdivided into primary and secondary stocks of petroleum Secondary stocks are considered to be distributed with other fuels, whereas primary stocks of petroleum are considered separately in order to calculate the effect of a concerted effort to avoid or include these targets (see estimates below)

Typically, only a fraction of the total available combustible material might actually burn in active, flaming combustion Here I assume this fraction to be 25% of the distributed fuels (cellulosic and polymeric materials, and secondary stocks of petroleum) for both the high and low estimates In this way the range of optical depth derived can be considered to be independent of any particular model, although more (or less) fuel might burn if the warring nations made a concerted effort to try to ignite (or avoid burning) the available fuel A 25% fraction might come about, for example, by associating ~65% of the total fuel with people who live in cities (the average proportion of city dwellers for Europe, the Soviet Union and the United States), and then burning 80% of the total fuel in cities, half in active, flaming combustion and half in longer-term, smoldering combustion Alternatively, most city fuels might burn in active combustion but, because of clustering of targets and overlap of ignition areas, only 40% of the fuel in cities actually ignites and burns The optical depths derived below could easily increase if the war involved, for example, attacks on oil rigs or on oil-producing countries whose whose fuel stores are not part of the inventory considered here Similarly, if attacks included population centres outside the countries included here, the optical depths would increase However, the NATO and Warsaw Pact countries contain 85% of the population of all countries in the developed world, and as the present model burns 40-80% of the urban fuels in these countries, it is certainly large enough to be considered a 'major' nuclear war On the other hand, ~30% of the population in the develped world is concentrated in the 100 or so largest cities (see Table 3 1 in ref 4), so that if 100% of the fuel of these cities is burned in active, flaming combustion, nearly the same total optical depth could be produced However, the purpose here is not to develop war models, but to show the range in optical depth expected from current knowledge for a given model These ranges can easily be adapted to other models

Smoke emission factor

The appropriate smoke emission factor in a large-area urban fire depends on a number of poorly estimated and poorly known factors Emission rates can vary[11,12], depending on the type of fuel, the ambient air temperature, the availability of oxygen, the radiant intensity (as determined by the proximity of nearby fires), the geometric arrangement of fuel, and so on Only very limited data from large fires are available, so most studies have used values consistent with the range of emission factors measured in laboratory-scale fires (see Table 3) These might be underestimates, if oxygen availability is truly limited in a large-area fire On the other hand, Carrier *et al*[13] have argued that oxygen availability should not be an issue, given the turbulent motions above the fire In view of the lack of credible data for smoke emission factors from large-area fires, the values adopted here are estimated from the limited available data, and are highly uncertain Table 3 also includes the range of estimates of the emission factor compiled in ref 10, primarily from laboratory data In the analysis below, I adopt a range of values for the emission factor, consistent with the best estimates chosen in refs 3 and 10, however, larger uncertainties apply because of the possible inapplicability of these emission factors to large-area fires

Optical properties of smoke

Just as the emission factor for smoke depends on the burning conditions and type of fuel, so does the chemical, morphological and optical character of the smoke Nevertheless, various authors have estimated the absorption and extinction coefficients for smoke, based on a variety of measurements that have tended to emphasize the data available from smoke emitted under flaming conditions The estimates are summarized in Table 4 In most recent evaluations, the optical properties of wood smoke are distinguished from those of smoke from fuels such as oil, plastics, and other polymers whose chemical structure has little available oxygen These latter fuels tend to produce much blacker smoke Table 4 shows wide variations in the estimates of the absorption and extinction coefficients for fresh smoke

In addition to variations in average optical absorption and extinction from different evaluations of these properties for fresh smoke, two mechanisms may act to make aged smoke less absorbing (see ref 4) The first mechanism is coagulation, which may act on short timescales (in very dense smoke plumes) or on longer timescales (from days to a week in the spreading global plume) to create larger particles These larger particles would absorb and scatter less radiation, if they are spherical Because some smoke particles are quite oily (and therefore spherical), while others appear as fluffy or chained agglomerates, it is not possible to predict the effects of coagulation on optical properties Chained agglomerate particles might become spherical if they coagulated with oily smoke particles, or if they were to condense and re-evaporate in a cloud—a process which might allow the chains to collapse[14] To the extent that the agglomerates remain in a chained formation, their absorption properties may not change significantly. Thus, in the following, I adopt two extremes In the first case, coagulation is assumed to have no effect on optical properties, in the second, coagulation is assumed to reduce extinction and absorption by the amounts estimated in ref 15 for several days of coagulation This additional consideration widens the discrepancy between the lowest and highest estimates of absorption coefficient by an additional factor of ~3 for the highly carbonaceous, absorbing smokes The extinction coefficients differ by a factor of >2 The absorption coefficient for less absorbing smoke is not significantly changed by coagulation

Fraction of smoke scavenged by rain

The last factor which contributes to estimates of the average optical depth is the amount of smoke that is removed by precipitation occurring in the smoke plume over the fire and in the

Table 5 Fraction of smoke removed by rain

† Fraction of smoke particles that enter cloud water by nucleation scavenging. The amount removed by precipitation may be less than this.

first few days after the war. Several authors have estimated that, especially for large, intense fires, large quantities of water will condense above the fire[16,17], but there have been few attempts to quantify how much smoke is removed. In both Hiroshima and Nagasaki, a 'black rain' fell, coincident with the fires which followed the nuclear blasts of August 1945[6]. The black rain is presumably smoke that has been scavenged by rain. It is not known how much of the smoke was scavenged or whether the experience in Nagasaki and Hiroshima should be considered to be typical.

The amount of smoke scavenged by rain depends, once again, on properties of the smoke which are poorly known. For example, the number of smoke particles that act as condensation nuclei for cloud drops depends on the highest level of supersaturation attained above the fire. This depends on the total number of smoke and debris particles, their size distribution, and their affinity for water. Furthermore, the highest level of supersaturation depends on the updraft velocity within the plume as well as the growth rate of the drops which form. As the size and composition of smoke particles from the large-scale urban fire are poorly known, it is difficult to predict how much nucleation scavenging might occur. Initial studies, which assume idealized spherical particles, indicate that for conditions considered typical of smoke above fires, all particles with radii greater than 0.1 μm (or ~50% of a log-normal distribution with a mode radius of 0.1 μm) might be scavenged in this manner[18]. However, further studies with a more realistic description of smoke particles are needed.

Once drops have formed, other mechanisms may also act to attach smoke particles to cloud drops. These include electrical capture, phoretic forces and turbulent motions, although Cotton[17] has estimated that <2% of the smoke particles might be captured phoretically. Cloud drops may or may not form precipitation-sized rain drops. The probability of this occurring depends on the initial size of debris and smoke particles and on the number that become nucleated to form drops. Pruppacher[19] estimated that, although most of the particles would enter cloud drops by nucleation scavenging, rainout of the smoke would be relatively small because of overseeding effects. However, only one size distribution was considered and the updraft velocity was only 1 m s^{-1}. Consideration of more realistic fire plume conditions may alter this conclusion. Once the drops become large enough to obtain a significant fall velocity, they may capture more smoke particles by impaction scavenging. The probability of this occurring also depends on the size of smoke particle (with larger particles being more likely to be scavenged).

The capture mechanisms described above apply to warm-rain precipitation only. Additional mechanisms and pathways for capture must be considered in the case of ice formation, which can also lead to release of the smoke particles. Because the saturation vapour pressure over ice is less than that over water, when ice begins to form, water on drops may evaporate and recondense on ice particles, thereby releasing any smoke that was previously captured by nucleation scavenging. Recently G. Tripoli (personal communication) has used the cloud model developed by Cotton[17] to estimate that this process could limit any rainout of the smoke above the fire to <20%. In addition to the near-immediate rainout of smoke above the fire, mesoscale atmospheric circulations may be set up which lead to rainout on longer timescales[20].

The theoretical analysis of scavenging and rainout is complex and difficult, and further work is needed. For this reason, many authors have simply guessed a fraction for smoke that might be removed by rainout. These guesses range from ~0 to 50% (see Table 5), although the real range of possibilities might include values up to 100% in some cases[21]. Here I consider the range from 0 to 50%. Obviously, the range of average optical depths obtained could be larger, for example, if rainout removed 90% of the smoke.

Calculated optical depths and climate

If we combine all the choices described above, emphasizing the smallest factors in one case and the largest factors in the second,

we obtain the range in absorption and extinction optical depths shown in Table 6 Table 6 lists separately the optical depths from cellulosic fuels, from distributed fuels producing highly carbonaceous smoke (polymeric materials and secondary stocks of petroleum) and from primary stocks of petroleum In the case of distributed fuels, one quarter of the total abundance in the NATO and Warsaw Pact countries, or 40–80% of the fuel in cities, is assumed to burn As shown in Table 6, the burning of polymers and petroleum may contribute significantly to the total optical depth To show its effect, we consider two models In the first, the contribution of primary stocks of petroleum to the total optical depth is not included This might result if the warring nations specifically tried to avoid targets, such as refineries, that would add disproportionately to the optical depth As warring nations have never yet refrained from attacking the economic base of their enemies, this may be an unlikely model, but it is interesting to calculate the consequences should studies of 'nuclear winter' cause nations to re-evaluate their war plans In the second model these targets are all included, so that 100% of the primary stocks of petroleum are burned Table 7 summarizes the high and low estimates of optical depth for these two cases If the primary stocks of petroleum are not included, the absorption optical depth varies from 0 2 to 4 2 Including these stocks increases the range of absorption optical depths to 0 4–6 1 In the first case, the low estimate is equivalent to 12 Tg of smoke with the optical properties assumed in ref 3 This increases to 24 Tg of smoke if primary stocks of petroleum are included This case is close to the lowest amount of smoke (20 Tg) considered by Malone *et al*[22] in an advanced three-dimensional climate simulation Their results are consistent with widespread temperature changes of −4 to −6 °C over the continents in summer The largest average optical depth calculated here is equivalent to almost 400 Tg of smoke (assuming the absorption coefficient from ref 3) This is somewhat less than the largest amount of smoke assumed by Malone *et al*[22] (500 Tg) and would, according to their results, lead to profound climate changes, particularly as its removal would be inhibited by changes to atmospheric stability

The range of values calculated here is disquieting, because I tried to choose values for each of the various factors that were thought to be a 'best estimate' by at least one of the authors cited here Although the range derived is similar to that quoted in ref 3, they developed their estimates from uncertainties about a median value, whereas the present estimates are developed using the best estimates from a number of authors The calculated range would be larger if we also considered the uncertainty estimates for each of the factors This is especially true for the range of values chosen for the emission factors In this case, the range of published values is not very large, but, because so few relevant data are available, the published range may not even include the correct value There are also uncertainties caused by the lack of good data on the optical properties of smoke and the effect of the clouds formed above large fires Furthermore, as discussed above, little is known about the scavenging and rainout of smoke in fire plumes Good data on the properties of smoke from large fires will only come from large fire experiments, but great care is needed in the design and interpretation of the large-scale fires which will be used in the re-analysis of the smoke source term The planned experimental programs sponsored by the United States Defense Nuclear Agency should be helpful but must not stop after only the first few experiments We must try to understand the more complex situations that will exist in a real nuclear fire In addtion, more and greater emphasis must be placed on understanding scavenging and rainout Here, progress may come through the development of advanced modelling capabilities, coupled with verification by large-scale fire experiments

Conclusions

Although our lowest estimates for $\bar{\tau}_a$ and $\bar{\tau}_e$ may produce only minor climatic effects, models can easily be constructed in which more fuel is burned, so that even in the low-estimate case, the estimate for $\bar{\tau}_a$ would correspond to a major climatic impact if the war takes place in the spring or summer On the other hand, it is entirely possible that such major effects could be avoided if the low estimates are correct and if targets such as refineries, oil and gas production fields and coal storage areas are avoided The effects on climate could also be lessened if the war took place during the winter[4] It seems clear, therefore, that 'nuclear winter' is not necessarily a probable outcome of nuclear war, although it is certainly possible The full range of possible impacts can never be completely narrowed because we cannot have access to the war plans of the nations of the world, nor predict the course of any given war once it began I have shown, however, that for the model considered here, that is, one in which 40–80% of the total distributed urban fuels are burned, further research is needed in order to be able to predict the effects on climate

Occultation determination of Neptune's oblateness and stratospheric methane mixing ratio

The occultation of a star by Neptune on 20 August 1985 was observed at 2.2 μm wavelength with telescopes at the European Southern Observatory (ESO) and the Cerro Tololo Inter-American Observatory (CTIO). The detection of a 'central flash' midway between immersion and emersion has allowed the determination of Neptune's oblateness, ε, and the atmospheric extinction at 2.2 μm, which is related to the stratospheric methane mixing ratio. We find $\varepsilon = (2.08^{+0.19}_{-0.18}) \times 10^{-2}$ *and, assuming a stratospheric temperature of 120 K, infer a value of 0.6% (with an uncertainty of a factor of 10) for the methane mixing ratio* (CH_4/H_2) *at 0.3 mbar. The latter value may indicate supersaturation of methane in Neptune's stratosphere.*

STELLAR occultations provide an opportunity to study upper planetary stratospheres and to determine planet oblatenesses, they also allow the detection of ring or arc systems around giant planets. Here we report observations of the occultation by Neptune of star no. 39 in the list by P. D. Nicholson, K. Matthews and G. Gilmore (personal communication) on 20 August 1985, made with the ESO 1-m telescope and the CTIO 1.5-m telescope. Both observations were made in the K band and with a sampling frequency of 100 Hz. An unexpected highlight of this experiment was the observation of a 'central flash' midway between immersion and emersion, when the star was behind the centre of Neptune. This event allows the independent determination of Neptune's oblateness and stratospheric methane mixing ratio. Here we focus only on the study of the flash. Isothermal fits and inversion of the immersion and emersion curves will be presented elsewhere, together with details of an arc structure detected around Neptune at Mauna Kea during the same night.

Observations

Figure 1 shows the occultation light curves and the structure of the observed flashes. A strong peak (~20% of unocculted stellar flux at ESO and ~15% at CTIO) appears first, followed by a wide plateau with several bumps and then a double-peaked structure, after which the signal decreases. The structures observed at the two sites are well correlated (see also Fig. 5).

Theory and modelling of the flash

Theory. The central flash, produced when the star was behind the central part of Neptune, is due to curvature of the limb perpendicular to the light of sight, which causes convergence of the light to the central area of the geometric shadow of the planet[1]. If, as a first approximation, we consider the planet to be spherical, we see that when the star is exactly behind the centre of the disk, the atmospheric refraction is radially symmetrical: the atmosphere is a spherical lens which focuses the light rays on its axis. For on-axis positions, the focusing of the rays is more efficient than spreading due to differential refraction, and this results in a sudden increase of the intensity (Fig. 2).

Because Neptune is significantly oblate, the limb of the shadow is approximately elliptical, and the atmosphere acts as an elliptical lens. The locus of perfect focusing is no longer restricted to the axis of the lens, but its projection in a plane parallel to the plane of the shadow is a curve called the evolute (or the caustic) of the ellipse. The light rays that fall near a given point on the limb converge to the centre of the curvature of the ellipse at the point concerned, and the caustic is then formed by the centres of curvature of the ellipse (see Fig. 15 of ref. 1).

Letting r_e and r_p be the equatorial and polar radii of the planet at the level probed by the flash, and B ($=-25.04°$) the planetocentric declination of the Earth, the equation of the limb of the shadow is

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \tag{1}$$

where a, the semi-major axis, is equal to r_e, and b, the semi-minor axis, is given by

$$b=\frac{r_e r_p}{\sqrt{r_p^2 \sin^2 B + r_e^2 + \cos^2 B}} \tag{2}$$

The apparent oblateness of the shadow is then

$$\varepsilon' = \frac{a-b}{a} = 1-(1-\varepsilon)(\cos^2 B + (1-\varepsilon)^2 \sin^2 B)^{-1/2} \tag{3}$$

where

$$\varepsilon = \frac{r_e - r_p}{r_e} \tag{4}$$

is the true ellipticity of the planet.

Modelling. To calculate the theoretical profile of the flash, we assume the atmosphere to be isothermal in the region probed by the flash (in particular, any horizontal gradient is neglected) and we use the following method[1]. For a point $M(x, y)$ within the shadow, the intensity $\phi(x, y)$ (normalized to the unocculted flux) is the sum of the contributions from the two to four M_i points of the limb whose normals intersect $M(x, y)$. The contribution from each point M_i is evaluated by solving the Baum and Code[2] equation with a scale height $H = RT/mg$ (where R is the gas constant, T is the temperature, m is the mean molar mass and g is the acceleration of gravity) and, to account for the curvature of the limb, the flux thus obtained is multiplied by the ratio of the radius of curvature of the ellipse at M_i to the distance $d = MC_i$, where C_i is the centre of curvature of the ellipse at M_i. As expected for caustics, the intensity becomes infinite on the evolute if one does not take into consideration the finite size of the star (in this case, 6.5 km radius at Neptune's distance, as estimated from the occultation by the Neptune arc observed from the Canada France Hawaii Telescope (B. Sicardy *et al.*, in preparation). To avoid tedious calculations, the profile of the flash is smoothed in one dimension only, along the most sensitive direction—that is, perpendicular to the evolute. Finally, to allow for atmospheric absorption along the path of the rays, we multiply the whole flash profile by a transmission factor $e^{-\tau}$. The intensity throughout the central flash profile is approximately proportional to the scale height near the ray's closest approach to the planet, the effect on the profile of a transmission factor $e^{-\tau} < 1$ is therefore indistinguishable from the effect of a reduction of the scale height by the same factor. In the absence of multiwavelength data, it is necessary to use independent information about the scale height in the region probed by the flash to decide whether an inferred value of the transmission factor represents a finite τ or instead a lower temperature.

Atmospheric level probed by the flash. For an isothermal atmosphere above the probed level, the refractivity of the atmosphere at the level probed by the flash is given by[3]

$$\nu_f = \frac{\theta(h_f)H^{1/2}}{(2\pi r_e)^{1/2}} \qquad (5)$$

where $\theta(h_f) = r_e/D$ is the light-ray bending angle at the altitude probed by the flash (h_f), and D is the Earth-planet distance (4.44×10^9 km). The number density at the altitude probed by the flash is given by

$$n_f = \frac{L\nu_f}{\nu_{STP}} = \frac{L}{\nu_{STP}}\frac{1}{D}\sqrt{\frac{Hr_e}{2\pi}} \qquad (6)$$

where L is the Loschmidt number ($L = 2.687\times10^{19}$ molecules cm^{-3}), and ν_{STP} is the refractivity of the atmosphere at standard temperature and pressure. For $g = 1{,}090$ cm s^{-2}, and an atmosphere of 90% H_2 and 10% He, we obtain $m = 2.2$ g, so $H(\text{km}) = T(\text{K})/2.88$, and $\nu_{STP} = 1.26\times10^{-4}$ at 2.2 μm (ref. 3). The pressure at the probed level is then $p_f = n_f kT$, where k is the Boltzmann constant.

The column density N_f of the atmosphere traversed by the light rays is

$$N_f = n_f\sqrt{2\pi r_e H}\ \text{molecules cm}^{-2} = \frac{Hr_e}{\nu_{STP}D}\ \text{km atm} \qquad (7)$$

with all the distances expressed in kilometres. Here $N_f = 1.564\times10^{-2}\ T$ km atm.

Fitting the flash profile

Oblateness of Neptune. Once the astrometry is fixed, the shape and height of the flash are determined by the four parameters r_e, ε, H and $e^{-\tau}$. Both the radius and the oblateness of the planet affect the profile of the flash by changing the size of the evolute (its typical dimension is $2\varepsilon' r_e$) and thus its position relative to the path of the telescope in the shadow. The flash profile is much more sensitive to ε than to r_e, and the uncertainty in ε (~20%[4,5]) is much greater than that in r_e (0.2%). We therefore fix r_e at 25,200 km in the calculations.

Occultation measurements have provided temperatures of ~150 K at the 1 μbar level[5-7], and far-infrared photometry indicates that the temperature is ~60 K at the 40 mbar level[8,9]. Appleby's[10] radiative convective models show that the temperature can vary from 70 to 150 K at the 0.1-1 mbar level, depending on the amount of aerosol heating and possible CH_4 supersaturation, but also that the temperature at this level must be >100 K to account for the high brightness temperatures observed at 20 and 35 μm. For our 'nominal' model, we adopted $T = 120$ K, the corresponding pressure is then 0.32 mbar.

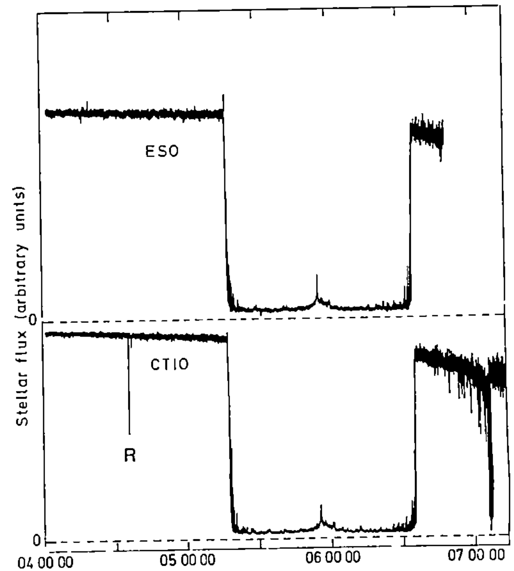

Fig. 1 Occultation light curves and the central flash as observed from ESO and CTIO. Each light curve is plotted at 1-s time resolution. The excursion labelled 'R' is caused by re-centering of the telescope.

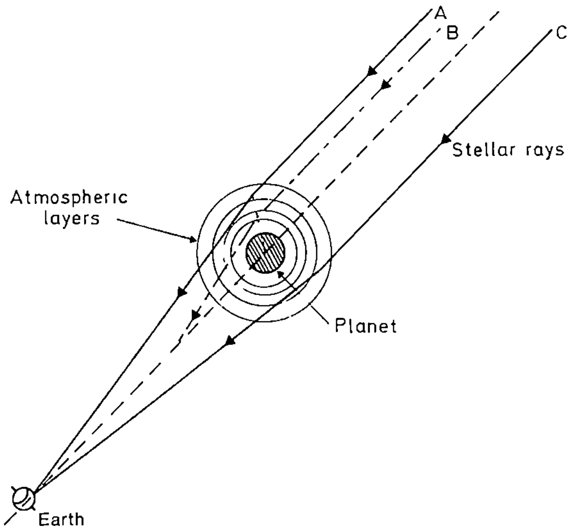

Fig. 2 Schematic explanation of the central flash for a spherical planet. Rays that traverse the atmosphere at different depths, such as A and B, are spread by differential refraction, in contrast, two rays which traverse the atmosphere at the same depth (such as A and C) converge to the same point on the axis and produce the flash.

We started with prediction astrometry provided by P. D. Nicholson (personal communication), which was derived from published occultation mid-times and Neptune shape parameters[4,5]. We used Neptune ephemeris data from the Annuaire du Bureau des Longitudes (1985) (P. Bretagnon, personal communication). To allow for the uncertainty in this initial astrometric solution, two additional parameters were left free: a possible shift Δs between the predicted and actual position of the observatory along the motion of the shadow, and the 'impact parameter' p_0, which is the distance of closest approach to the centre of the shadow.

Our method for fitting the flash was as follows. For a reasonable set of parameters ($\varepsilon = 0.021$, $T = 150\ K$, $e^{-\tau} = 1$, position angle of the projected north pole $P_n = 22.9°$, as determined from the angular momentum of the Neptune-Triton system, assuming a Triton to Neptune mass ratio of 0.00128 (ref. 11)), the theoretical profile was calculated, and cross-correlated with the observed profiles, to obtain the central flash times. We obtained $t =$ 05 55 19 UT for the ESO flash and $t =$ 05 55 21.0 UT for the CTIO flash. Using these times, P_n was determined to be 20.1°. A simultaneous least-squares fit to the ESO and CTIO flash profiles with P_n as an additional parameter yielded $P_n = 20.0°$, in good agreement with the results of the first method. As a

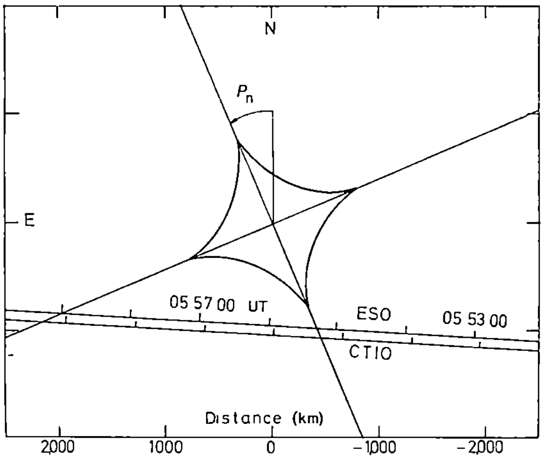

Fig 3 Path of ESO and CTIO relative to Neptune's evolute as projected in the plane of the sky For this diagram, r_e is taken to be 25,200 km, the apparent oblateness of the shadow, $\varepsilon' = 0\ 0171$ and $P_n = 20\ 1°$

further check on the uncertainty in P_n, we measured the times of the peak central intensity at both stations by performing a least-squares fit of a gaussian profile to only those data points near the peak This method yielded $P_n = 19\ 3°$ We estimate the uncertainty in determination of central peak times to be 0 2 s, and the uncertainty in P_n to be 1° Assuming a zero mass for Triton, Harris'[11] ephemeris would yield $P_n = 21\ 6°$ The disagreement with Harris'[11] ephemeris thus appears to be significant, but must be taken with some caution as small atmospheric density fluctuations can cause significant systematic distortions of the central intensity profile The shift Δs was determined to ensure that each observatory crossed the evolute axis at the time of the flash Then, for a grid of points (ε, p_0), theoretical profiles were calculated for a transmission equal to unity, and for each point of the grid, a linear regression was made to find the transmission and the zero level that best matched the observed curve, and the corresponding residuals were calculated The best fit was obtained for a particular set of parameters ε, p_0 and $e^{-\tau}$

Figure 3 shows the paths of the observatories with respect to the evolute in the plane of the shadow, Table 1 summarizes the results for the two observatories As explained above, the factor $e^{-\tau}$ for any assumed temperature (in K) can be scaled from the results presented in Table 1 by multiplying the tabulated values by $120/T$ Note that the agreement between the two observatories is satisfactory Figure 4 shows the quality of the fit in the central part of the flash Our determination of Neptune's oblateness at ~0 3 mbar is $\varepsilon = 0\ 0208^{+0\ 0019}_{-0\ 0018}$ The location of the centre of the planet, as deduced solely from our model fit to the central flash, is in excellent agreement with the oblateness and centre location determined from the limb profile fitted solely to the edge occultation points (discrepancy in centres is $<H$, data to be published elsewhere)

As shown in Fig 5, the model predicts a weak secondary peak at ~05 58 UT, caused by the approach of the occultation tracks to the eastern tip of the evolute pattern (Fig 3) Although the data show a general plateau in this region, secondary peaks in the data do not appear at the predicted time Adjusting the model so as to force a detailed fit only to the secondary peaks violates other constraints Thus, for example, it becomes impossible to fit the main peak correctly, and the location of the planet's centre must be moved away from agreement with the limb profile centre It is possible to argue (to be presented elsewhere), that the secondary peaks in the central flash region are caused by modest deviations of atmospheric refractivity from the smooth, symmetric model assumed here, and that these peaks are produced by essentially the same type of atmospheric disturbances responsible for the well-known rapid intensity fluctuations seen during immersion and emersion Thus a least-squares fit to a model representing the mean properties of the atmosphere should yield valid results, although it will not fit the data in every detail In particular, because scattering by refractivity fluctuations must conserve energy, the mean intensity level in the entire flash region will be largely unaffected by the fluctuations, and the inferred value of $e^{-\tau}$ will be correspondingly conserved

Methane mixing ratio in Neptune's stratosphere. The inferred opacity along the path followed by the light rays is related to Neptune's 2 2-μm absorbers Note that Rayleigh scattering provides negligible extinction (10^{-4}–10^{-5}) at 2 2 μm for paths of a few km atm (ref 12), as is also the case for scattering by fine aerosols[12,13], and that at the pressure probed by the flash (<0 5 mbar), H_2-H_2 and H_2-He pressure-induced absorptions are negligible Thus, the observed absorption must be attributed entirely to methane

In the region of transmission of the filter ($\lambda = 2\ 18$ μm, $\Delta\lambda = 0\ 42$ μm) the CH_4 rotation-vibration bands are those of the so-called octade Three of the eight bands of the octade ($\nu_1 + \nu_4$, $\nu_3 + \nu_4$, $\nu_2 + \nu_3$) have been well studied, the others being much weaker[14-16] Only these three bands were considered here For each of the three bands, each P, Q and R sub-branch shows J-multiplets Integrated intensities of each multiplet up to $J \simeq 14$ were provided by the Laboratoire de Spectronomie Moléculaire at the Université de Dijon (J -C Hilico, personal communication), together with the number of lines involved in each multiplet Because of the large path (~2 km atm) we had to consider even weaker lines (up to $J \simeq 18$), whose intensities were evaluated by assuming they are governed by the exponential term, $\exp(-hcE/kT)$ (where h is Planck's constant, c is the speed of light and E is the lower energy level of the transition) Because of the quickly increasing number of lines in each J-multiplet, we used for each P, Q and R J-multiplet of each band, a band model of non-overlapping independent lines of unequal intensities, assuming an exponential distribution of the intensities[17] For a given multiplet, where σ is the mean line intensity, the probability that a line has an intensity between S and $S + dS$ is $\sigma^{-1} e^{-S/\sigma}\, dS$, and the mean transmission over the band is $T = \exp(-\bar{A})$, where

$$\bar{A} = \frac{1}{\delta} \int_0^{\infty} e^{-S/\sigma}\, dS \int_{-\infty}^{\infty} [1 - \exp(-Sf_\nu a)]\, d\nu \qquad (8)$$

in which δ is the mean spacing of the lines, a is the column density of the absorber and f_ν is the line profile In our case,

§ Assuming a stratospheric temperature $T = 120$ K

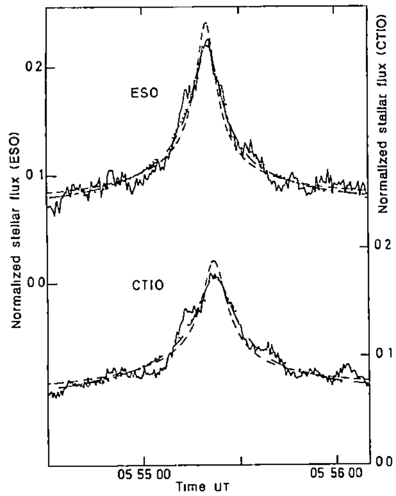

Fig. 4 Fitting of the central part of the flash for various values of ε For ESO ———, ε = 0 0214, – – – –, ε = 0 0203, , ε = 0 0190 For CTIO ———, ε = 0 0227, – – – –, ε = 0 0212, , ε = 0 0195 The data (——) are plotted at a time resolution of 0 5 s

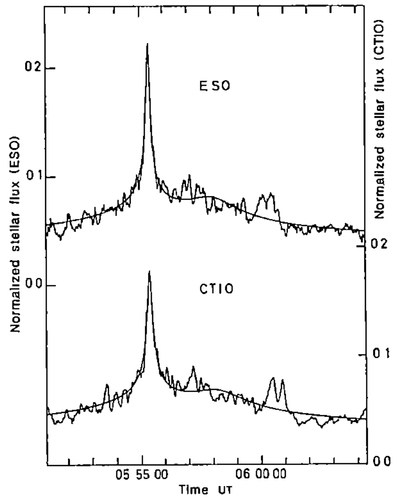

Fig 5 Fitting of the entire flash profile For ESO, ε = 0 0203, for CTIO, ε = 0 0212 The data are plotted at a time resolution of 2 s

the Doppler width $\alpha_D = 4 3\times10^{-7}\ \nu\sqrt{T/M}$ (where M is the molar mass of CH_4) is much greater than the Lorentz width α_L (typically $\alpha_D = 6\times10^{-3}$ cm^{-1} versus $\alpha_L = 3\times10^{-5}$ cm^{-1}), and the cores of the lines have a Voigt profile[18], the far wings being Lorentz-shaped

For each multiplet, the integrated intensity and the number of the lines provides σ and δ Finally, for each temperature and various methane mixing ratios, we obtained the general transmission over the filter as the product of the transmission of each multiplet

The methane mixing ratio was adjusted to match the observed opacity, and our conclusions are summarized in Table 1 If $T = 120$ K (nominal model) we find a methane mixing ratio of 0 6% with an uncertainty of a factor of 10 If $T = 150$ K, the methane mixing ratio is 1% with a factor of 4 uncertainty If $T = 100$ K, we can derive only an upper limit of 2%, with 0 1% as the most probable value

Discussion

Oblateness. Measurements of planetary oblateness are of interest because they are related to internal structures through the gravitational fields To first order, the following relation holds[5]

$$\varepsilon = \tfrac{1}{2}J_2(3 + 1/\Lambda_2) \qquad (9)$$

where J_2 is the gravitational quadrupole moment, and Λ_2 is the second-degree response coefficient as defined by Hubbard[19] the smaller the value of Λ_2, the more centrally condensed is the planet

Recent determinations of ε were obtained from the results of the 15 June 1983 occultation by Neptune From separate analyses of astrometric solutions for various stations, Hubbard *et al*[5] derived $\varepsilon = 0 022 \pm 0 004$, whereas French *et al.*[4] found $0 0191 \pm 0 0017$ We find here an intermediate value of $\varepsilon = 0 0208^{+0 0019}_{-0 0018}$, which is in fairly good agreement with these two determinations It must be emphasized that, due to the very unusual path of the observatories in the shadow (they passed very close to the evolute but did not cross it), the shape of the flash is very sensitive to the oblateness of the model, which accounts for the small uncertainty in our determination of ε

J_2 is equal to 0 0037-0 0043, as determined from the motion of Triton[11] Such values yield $\Lambda_2 = 0$ 12-0 15, which would imply that Neptune is less condensed than Uranus ($\Lambda_2 = 0 09$)

Methane mixing ratio Since the discovery of emission features due to methane at 7 μm in the spectrum of Neptune[20], there have been strong indications that methane could be supersaturated in Neptune's stratosphere Even before this observation, Macy and Trafton[21] had suggested methane supersaturation from brightness temperatures in the 20-μm region, and had found a stratospheric methane mixing ratio of 2×10^{-3} Courtin *et al*[22] also derived a methane mixing ratio of 2×10^{-3}, from analysis of the 8-μm spectrum of Neptune However, Gillett and Rieke[23] suggested that the high brightness temperatures at 8 μm can be explained in terms of a high stratospheric temperature instead of methane supersaturation, and they considered the possibility of a methane mixing ratio as low as 10^{-6}, with a stratospheric temperature of 150 K Macy[24] reanalysed these works, and derived a methane mixing ratio of 10^{-2}-10^{-3} in the stratosphere More recently, Orton *et al*[25] reported the first unambiguous detection of Neptune in the 10 3-11 4-μm region and derived a stratospheric methane mixing ratio of 0 01-0 1, probably approximately equal to the tropospheric value Our observation, which for an assumed stratospheric temperature of 120 K implies $CH_4/H_2 = 0$ 1-1%, also suggests a large enrichment of stratospheric methane, compared to the case where methane is trapped at the tropopause (assuming a tropopause temperature of 53 K (ref 9), the stratospheric mixing ratio would be 5×10^{-5}) These results require that methane is migrating through the tropopause cold trap, and several explanations have been proposed[8,25,26] (1) injection of methane into the stratosphere by strong, localized atmospheric convective motions, (2) transport of small methane particles into the warm stratosphere where they re-sublime, upward eddy diffusion overcoming the sinking of particles due to gravity, (3) an atmosphere so stable and homogeneous and nucleation sites so rare that methane remains supercooled in the inversion region, and (4) the existence of substantial areas where the inversion level is much warmer (leaks in the cold trap) Note that Appleby's[27] Neptune model suggests that the stratospheric methane abundance is near local saturation, a mechanically unstable situation that could, by temperature perturbations, produce an 'inverted cloud'

Conclusion

We have here derived values for Neptune's oblateness and stratospheric methane mixing ratio from an isothermal model of the central flash profiles We emphasize that the oblateness is derived solely from the flash profiles, and does not take into account the emersion and immersion times A determination of

Neptune's oblateness from emersion and immersion times will be presented elsewhere, and comparison of the results will be a good test for the two methods Nevertheless, the fact that the times and shapes of the two flashes observed independently are compatible with the relative positions of the observatories (see Table 1) gives us confidence in the model presented here This model, however, does not fit the complex structure of secondary bumps The effects of non-isothermal wave-like structures in the atmosphere are under study and will be presented elsewhere

LETTERS TO NATURE

Have burnt-out galaxies and galaxy clusters been detected?

Joseph Silk

Institut d'Astrophysique de Paris, 98 bis, Boulevard Arago,
F-75014-Paris, France and Department of Astronomy,
University of California, Berkeley, California 94720, USA

Close pairs of quasars are receiving much attention for two reasons. The image doubling may be due either to gravitational lensing of a single quasar by an intervening object or to physical clustering, that is, spatially close quasars with similar redshifts. Here I show that an elevated rate of star formation may be responsible for burning out protogalaxies in the densest galaxy clusters, leading both to formation of candidate lenses and to an enhanced probability of close association of quasars in regions of apparently low galaxy density.

Interpretation of identical multiple images of quasars as gravitational lenses requires the lensing objects to be at least as massive as a galaxy[1,2] and in one recent case a galaxy cluster[3], but in several cases to lack the optical luminosity one would ordinarily expect For the most extreme example, the quasar pair[3] 1146+111 B,C with a separation of 157 arc s, the hypothesized lens mass is $\geqslant 10^{15} M_\odot$ In the absence of any very rich galaxy cluster, candidate lenses include a cosmic string[4,5] and a supermassive black hole[6] The recent discovery[7] of spectral differences between the image pair 1146+111 B,C however, suggests that one may in this case be seeing a physically-associated quasar pair This is not easy to understand unless quasars are much more common in large groups or rich galaxy clusters at redshift $z \simeq 1$ than at the present epoch[8] An equally serious problem is the lack of candidate objects of galactic mass for lensing some of the several arc-second separation quasar pairs alternatively, in these cases too, the physical association of quasars must have been enhanced

A possible explanation arises naturally in standard galaxy formation models I will argue that there is a fundamental bias against detecting luminous matter in the densest large-scale regions of the Universe, namely great clusters of galaxies This provides a reasonably natural mechanism both for 'hiding' galaxies to provide candidate lensing objects and for enhancing the frequency of occurrence of the quasar phenomenon in such regions

Consider a situation in which galaxy clustering developed hierarchically after galaxies formed, as in the cold dark matter model[9], although this assumption is not crucial to my argument Vigorous star formation at the present epoch is tidally induced, whether by generation of density waves excited by the tumbling or rotation of a central bar[10] or by the close approach of a companion galaxy[11] Indeed, the most intense bursts of star formation that are identified with IRAS (the Infrared Astronomical Satellite) galaxies are associated with interacting galaxies[12] From the theoretical point of view, the non-linear response of a cold system greatly amplifies even weak tidal perturbations[13] The net effect is to enhance gas cloud collisions and dissipation, initiate large-scale gravitational instabilities, and trigger star formation Empirically, the IRAS studies suggest that the specific star formation rate is enhanced by one or even two orders of magnitude in the most intense star bursts, such as that in Arp 220, relative to the solar neighbourhood

Little is known about star formation in protogalaxies But it is virtually certain that when the old spheroidal stellar component formed, the specific star formation rate was anywhere between two and three orders of magnitude higher than it is today in the solar neighbourhood It was necessary to have formed $\sim 10^{11} M_\odot$ of low-mass stars in a timescale that is estimated to be $\sim 10^9$ yr It cannot be much less, because stellar evolution calculations and chemical evolution models require this time to build up the heavy elements that are seen in the old stars and to account for the spectral synthesis of elliptical galaxies[14] It cannot be much longer, because the oldest stars in our Galaxy show no evidence of any spread in formation epoch[15] It is tempting to identify the initiator of protogalactic star formation activity with the similar trigger that is observed today in starburst galaxies Indeed, strong tidal interactions are inevitable if galaxies formed hierarchically from a Zeldovich spectrum of primordial adiabatic, gaussian density fluctuations, in which small-scale power has not been suppressed, as in the cold dark matter model[9] Moreover, all available evidence suggests that the protogalactic initial stellar mass function (IMF) spanned a similar mass range to the present day IMF[16,17], thereby helping to justify our confidence in taking over inferences about star formation in nearby galaxies

One additional ingredient of star formation has received considerable attention The efficiency of star formation measures the mass fraction of gas that has been converted into stars In the solar neighbourhood, the long-lived, low mass ($\leqslant 1 M_\odot$) stars account for most ($\sim$85%) of the total star formation rate[18] In regions of vigorous star formation, however, including the inner galaxy[19], the situation appears to be rather different. In particular, in starbursts, the ratio of the observed massive star formation rate to the total gas supply implies that relatively few low mass stars can be forming[20]. The IMF cannot extend with any appreciable power below 2-3$M_\odot$, and in some cases, 5-10$M_\odot$. There are plausible, although hardly rigorous, theoretical arguments concerning why this should be so[21,22].

The following inference now becomes logical, and possibly inevitable. If there are any regions of the Universe so dense that tidal encounters between protogalaxies occurred at a rate large enough to stimulate star formation to a level up to and even beyond that seen in starbursts, then few very-low-mass stars could have formed before massive star formation had effectively depleted the net gas supply. If the star-forming phase in a proto-elliptical continues for $\sim 10^9$ yr, there is enough time to form many low-mass stars. But if it lasts only $\sim 10^8$ yr, low-mass stars may barely form at all. The evidence for this is largely circumstantial. Star formation bursts typically last $\sim 10^8$ yr, and fail to form low mass stars, whereas low mass stars do form over a much longer timescale, some several billions of years in the solar neighbourhood[23]. This bimodality between short-lived massive and long-lived low-mass star formation provides an attractive explanation of the local paucity of metal poor G-dwarfs in the disk[24]. Hence I conclude that in any region where the characteristic tidal interaction timescale between galaxies is as short as $\sim 10^8$ yr, one would be in grave danger of exhausting the gas supply without producing a significant number of low-mass stars. In 10^8 yr, most of the mass lost by stellar evolution of massive stars is recycled: if the low-mass cutoff in the IMF is above $\sim 10M_\odot$, essentially all the initial protogalaxy mass is cycled into compact remnants. With an IMF $dN(m)/dm \propto m^{-3}$ for massive stars[25], at most 20% of the initial mass is returned even if the low-mass cutoff is $\sim 5M_\odot$. The bulk of the initial mass is trapped in compact remnants. Evidently, with three or more generations of star formation, one would consume $\gtrsim 90\%$ of the initial gas supply even if the star formation efficiency is $\sim 50\%$ (as is required to form bound star clusters). Any stars of lower mass would presumably not have had time to form in significant numbers because their formation rate is too low. Exactly why bimodal star formation occurs is not fully understood, but there is ample circumstantial evidence, both from our Galaxy and from other galaxies, that massive star formation occurs at a high specific rate without accompanying low-mass star formation, while low-mass star formation proceeds at a more leisurely pace, and is generally accompanied by some massive star formation[19,24]. Alternatively, verification of a flat IMF as may be present in metal-rich galactic globular clusters[26] would show that some bound stellar systems are capable of eventually becoming seriously deficient in visible stars relative to those with a solar neighbourhood IMF[27]. This directly suggests that metal-rich galaxies could burn out after successive episodes of massive star formation have exhausted the gas supply.

Consider the double quasar 1146+111 B,C with a separation of 157 arc s. I first assume that the multiple images are due to a non-singular gravitational lens. Placing the lens at the optimal redshift to minimize its inferred mass, together with the observed separation between images, specifies the gravitational potential well of the lensing object, apart from a geometrical uncertainty[28]. Assuming the lens to be spherical, one infers a surface density $\Sigma \gtrsim 1$ g cm^{-2} and virial velocity dispersion $V_c \simeq 3{,}000$ km s^{-1}. If it is indeed a cluster of galaxies, the galaxy crossing timescale is $V_c/G\Sigma \simeq 10^8$ yr. This dynamical timescale is sufficiently short (a typical value for Abell clusters is $\sim 10^9$ yr) that one may expect tidal interactions to have had an important role in cluster evolution.

To evaluate the role of tidal heating, I use an effective cross-section for energy transfer derived from numerical simulations[29], $\sigma_E = 30r_e^2(V_*/V_c)^3$, where r_e is the effective radius of a galaxy, taken to have a de Vaucouleurs profile and to all be identical, and V_* is the isotropic r.m.s. stellar velocity dispersion within a galaxy. The heating rate is

$$E/E = 1.4(G\Sigma)^2\sigma_E/r_eV_*^2V_c = 0.7\Sigma^2r_3V_{*,300}V_{c,3000}^{-4}(10^9\text{ yr})^{-1}$$

where $r_3 = r_e/3$ kpc, $V_{*,300} = V_*/300$ km s^{-1} and $V_{c,3000} = V_c/3{,}000$ km s^{-1}. The actual situation would probably have been even more extreme, because during the initial collapse of the cluster the galaxy velocity was $\ll V_c$ and protogalaxies had considerably larger effective radii. Evaluation of E/E $(= n_c\sigma_EV_c)$ for parameters typical of the Coma clusters of galaxies ($n_c \simeq 200$ Mpc^{-3} in the core[30]) yields, for example, only $E/E \simeq 0.01(10^{10}\text{ yr})^{-1}$. Thus E/E is some three orders of magnitude larger for the hypothesized cluster that is lensing 1146+111 B,C.

In the case of cold dark matter with primordial density fluctuations described by the usual power spectrum $|\delta_k|^2 \propto k^n$, I find that for scales just going nonlinear at redshift z, $E/E \propto (1+z)^{2(n+5)/(n+3)}$, or over rich cluster scales where $n \simeq -1$ for a Zeldovich fluctuation spectrum, it follows that $E/E \propto (1+z)^4$ provided $V_* < V_c$. The density of the Coma cluster core corresponds to turn-around at background density equal to about $(1/200)\rho_c \simeq 10^{-27}$ g cm^{-3}, where ρ_c is the observed core density, or at $1+z \approx 6\Omega^{-1/3}$ if Hubble's constant $H_0 = 50$ km s^{-1} Mpc^{-1}. Hence galaxy formation at $1+z \gtrsim 10$ would have resulted in producing burnt-out galaxies only when clusters rather rarer (earlier forming) than Coma first collapsed. Abell clusters contain $\sim 5\%$ of luminous galaxies, and their frequency corresponds to their being $\sim 2\sigma$ fluctuations in a primordial gaussian fluctuation spectrum appropriate to cold dark matter models[31]. Clusters which would have induced burn-out are accordingly $\sim 3\sigma$ fluctuations, since $(\delta\rho)_c \simeq (1+z_c)(\delta\rho/\rho)_{r.m.s.}$, and should be relatively rare, amounting at most to ~ 1 per every 5 Abell clusters over the same filtering scale (the number density of density peaks being proportional to[32,33] $\nu^2\exp(-\nu^2/2)$ for $\nu\sigma$ fluctuations if $\nu \gg 1$).

I conclude that galaxies in clusters as extreme as that inferred to be producing 1146+111B,C would have undergone extremely strong tidal interactions during the initial collapse of the cluster, as well as subsequently. Such clusters should be rare compared with Abell clusters, but still sufficiently frequent to lens quasars with reasonable probability. Galaxy burn-out may even be a common enough phenomenon to account for some of the lenses which produce quasars pairs with arc-second separations: a definite prediction of my model is that there should also be a rich cluster of burnt-out galaxies in such cases, so that broad separation ($\gtrsim 100$ arc s) doubling should be sought in the fields of putative lenses where no luminous galaxy candidate has hitherto been found.

Next, I consider the possibility that formation of burnt-out galaxies may also be associated with an enhanced frequency of occurrence of quasar pairs. The tidal interactions that are able to stimulate massive star formation are also capable of driving molecular clouds and stars onto radial orbits which fuel the massive black hole that may already have formed at the centre of a galaxy. Precisely when or how such massive holes form is a contentious issue, but it is generally believed that the fuelling of such a hole of $\sim 10^8 M_\odot$ at a rate $\gtrsim 10\ M_\odot$ yr^{-1} is responsible for the quasar phenomena. Indirect evidence from absorption line studies suggest that quasars at $z \gtrsim 1.2$ are indeed in rich clusters[34,38], while direct imaging reveals that low-redshift quasars apparently avoid rich clusters[39]. As quasars evolve strongly in luminosity with redshift, this provides circumstantial evidence that the rich cluster environment may enhance quasar activity. The burnt-out galaxy hypothesis may render many of the associated galaxies sub-luminous, others, however, may be caught in their luminous protogalactic starburst phase. It is intriguing that the probable narrow emission line galaxy[35] at $z = 3.218$ that is a companion to the quasar PKS1614+051 is unusually luminous for a normal galaxy, and is perhaps the best candidate to date for a protogalaxy with the characteristic strong

Ly-α emission and compact appearance that models[36] predict

Finally, I note that one prediction, if a rich galaxy cluster is responsible, either by locally enhancing the spatial frequency of quasars or by lensing, for the quasar pair 1146+111 B,C, is that gas infall and ensuing heating could lead, at least in the case of the lens hypothesis, to a potentially detectable Sunyaev-Zeldovich microwave background anisotropy[37] and, more seriously, to excessive hard X-ray emission, J P Ostriker and J S have estimated (unpublished) that the thermal bremsstrahlung X-ray flux should be $\sim 10^{11}$ $(f_b/0\ 1)^2$ erg cm^{-2} s^{-1} keV^{-1} up to $\sim kT \simeq 30$ keV, where f_b is the mass fraction of the cluster in diffuse gas, and is probably well above the HEAO-1 all sky survey threshold if $f_b \simeq 0\ 1$

Burnt-out galaxies avoid this difficulty, because the available gas supply was mostly exhausted in forming massive stars Any left-over gas would have participated in a cluster cooling flow, the high density of which should have led to strong cooling in the cluster core and galaxy formation in the same tidally stirred-up environment where the burnt-out galaxies previously formed There should be some residual gas, however, at a density low enough that cooling should be unimportant (that is $f_b \simeq 0\ 01$) This means that up to $\sim 10^{13} M_\odot$ of hot gas could be present, and it would contain processed matter, including dust Thus the search for diffuse matter in the dark cluster that may be responsible for the quasar pair 1146+111 B,C should be pursued at X-ray, microwave and infrared wavelengths More generally, the rarity of the burnt-out clusters guarantees that any contribution to the cosmic background light should be negligible However, the possibility of observing vigorous starburst activity in the vicinity of high-redshift quasars deserves further attention This activity could manifest itself, for example, in producing extended emitting or absorbing clouds of low ionization state and with velocity dispersions of up to $\sim 1{,}000$ km s^{-1} that are characteristic of vigorous starburst activity

The investigation reported here of the variable source Circinus X-1 (Cir X-1) reveals that it is embedded in a nebula of steady radio emission extending over several parsecs, orders of magnitude larger than the binary stellar system responsible for the fluctuating component of emission (detected at X-ray, radio and optical wavelengths). This is in marked contrast to most X-ray binaries, where an envelope of radio emission is conspicuously absent. There are difficulties in explaining the emission, but analogies with SS433 and the Crab nebula suggest possible models.

X-ray[1], optical[2], infrared[3,4] and radio studies[2] indicate that Cir X-1 is an eccentric double-star system, with one component of the binary being very compact, possibly a neutron star or a black hole The 16 5-day periodicity, manifest across the observed frequency spectrum[5], implies an orbital semimajor axis $\leqslant$0 5 AU H I absorption measurements[6] yield a firm lower limit to the distance of 8 kpc At this distance the binary orbit subtends an angle $\leqslant 10^{-4}$ arc s, below the resolution limit of even very long baseline interferometry (VLBI) Nevertheless, Preston *et al*[7], using VBLI, reported a quiescent component of emission with angular size $\geqslant$0 2 arc s at 2 3 GHz and Haynes *et al*[2] reported evidence of an extended radio source at 1 4 GHz

The measurements presented here were made with the Molonglo Observatory Synthesis Telescope (MOST), which operates at 843 MHz, at the declination of Cir X-1 a 12-h synthesis observation[8] yields a beam of 43×52 arc s A contour diagram of Cir X-1 and the surrounding region is shown in Fig 1

The fact firmly established by the present results is that the variable compact source Cir X-1 is embedded in a radio nebula extending over ~5 arc min east-west and ~10 arc min north-south which shows no variability The integrated flux of the nebula at 843 MHz is 0 56 Jy

The compact object in Fig 1 at RA 15 h 16 min 48 6 s and dec −56°59′11 4″ (1950 coordinates are used throughout this paper) coincides with the X-ray source[1] Table 1 compares our best estimate of its position with the position measured by Argue and Sullivan[9] for the red star identified with the X-ray source and the position of the compact 2 3-GHz source measured using VLBI[10]

The compact source is a well-known radio variable[2] Between May 1983 and June 1985 at 843 MHz we found that the flux

Table 1 Compact object associated with Circinus X-1

Object	Position (B1950) RA	Position (B1950) Dec	Ref
MOST compact object	15 h 16 min 48 58±0 7 s	−56°59′ 11 4±0 5″	This paper
Red star	15 h 16 min 48 436±0 022 s	−56°59′ 11 4±0 28″	9
2 3 GHz VLBI object	15 h 16 min 48 37±0 04 s	−56°59′ 11 6±0 3″	10

Uncertainties in the MOST positions are dominated by an assumed 0 5 arc s uncertainty in ionospheric refraction

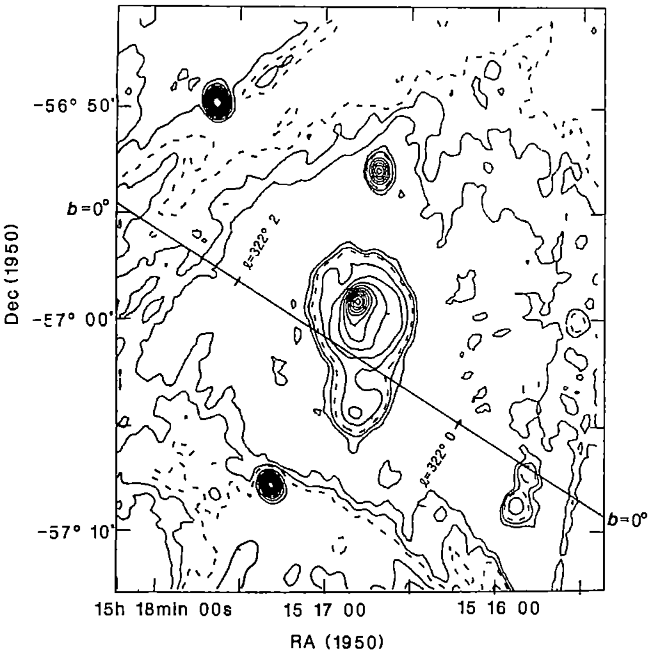

Fig 1 843-MHz map of the Circinus X-1 region obtained by integrating seven 12-h synthesis maps made with the MOST between May 1983 and June 1985 Contours are shown at levels of 1, 3, 5 (dashed), 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85 and 90 mJy per beam area

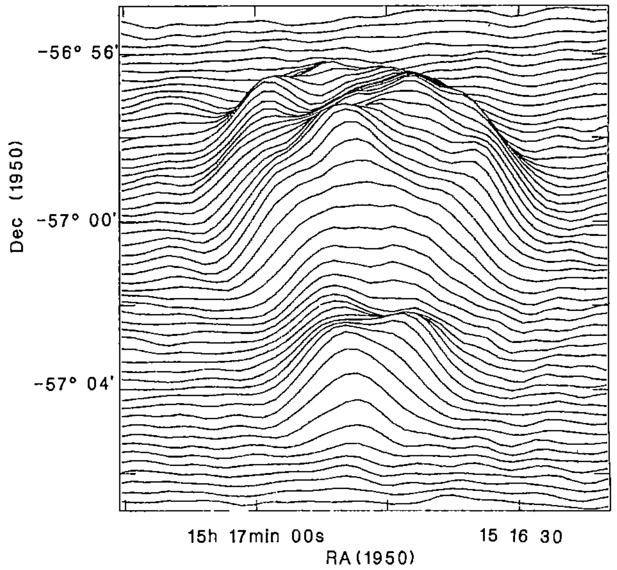

Fig 2 Perspective view of the nebular region surrounding Cir X-1 obtained by subtracting the 843-Hz emission from the point radio source associated with Cir X-1 from the data shown in Fig 1

density varied between 40 and 88 mJy The belief that the X-ray, radio and optical emission all emanate from Cir X-1 ultimately rests on the time variable correlation[2], for example, detailed monitoring in April 1982 showed radio intensity changes clearly correlated with the 3-6-keV X-ray intensity over the same time (L Kaluzienski, personal communication)

To study the detail of the nebula, we have subtracted the point radio source centred on Cir X-1 as shown in Fig 2 The most prominent part of the nebula is approximately centred on the compact component and adjoins a weaker and narrower component to the south centred near RA 15 h 16 min 47 s, dec −57°04′ Earlier, lower-resolution measurements[2,5] showed a quiescent source which we now assume arose predominantly from the diffuse nebula rather than from the compact variable source These measurements may be combined with the present 843-MHz results ($S_{843} = 0\ 56$ Jy) to yield a distinctly non-thermal spectral index of $\alpha \simeq -0\ 5$ ($S \propto \nu^{\alpha}$) Non-thermal sources of this intensity have a spatial density of ~1 per 3 square degree, and Cir X-1 coincides with the nebula's centre to within 1 arc s, the probability of a chance coincidence is then $\leqslant 1$ in 3,000 Thus, we conclude that the whole nebula is physically associated with Cir X-1 rather than a mere line-of-sight coincidence

Cir X-1 has several characteristics in common with Cyg X-1 (refs 11, 12) However, as far as we know, Cyg X-1 displays no extended radio component comparable with that associated with Cir X-1

In attempting to explain the extended distribution we consider two general types of model (1) the nebula is the remnant of an earlier active phase which no longer persists (2) The nebula has its energy supply maintained by continuous injection from a central engine The first interpretation corresponds to the typical supernova explosion In this case, we should expect to find a limb-brightened source There is no evidence of this in Fig 1, even when allowance is made for the limited angular resolution Furthermore, the nebula has a surface brightness that would be anomalously low for a typical shell supernova remnant of this size[13]

In the second kind of model, (2) the Crab nebula represents one variety of continuous injection model In this example, the central engine is a rotating neutron star, and energy transfer to the surrounding nebula may be accomplished by low-frequency electromagnetic waves[14] or by charged particles accelerated to ultra-relativistic energies in the enormous electric fields produced by the induction[15] Either process requires that the central engine be in a highly evacuated cavity Such processes are thus expected to be inoperative in Cir X-1 because it is an eccentric binary system[16,17] with a high rate of accretion from a 'normal' star to a 'compact' star and the resulting mass flow may smother the energy transfer process On the other hand, SS433 (refs 18, 19) another variable binary-star system, produces collimated jets which do successfully escape from the binary system and are not smothered by the mass transfer

The Cir X-1 flares have the characteristics of the van der Laan expanding radio source model[16] This leads us to suggest, as another variant of the continuous injection model, that the extended nebular is the accumulation of the energetic particles and plasma ejected during the flaring activity

Clark *et al* have argued that Cir X-1 is a runaway binary system According to this theory Cir X-1 was ejected from the supernova G321 9−0 3, the centre of which is some 25 arc min south, at the time of its eruption If this could be substantiated, it would rule out the possibility that the nebular surrounding Cir X-1 is itself a supernova remnant, and render a continuous injection model amost inescapable The southward extension of the radio nebular would also fit naturally into such a picture This model requires an asymmetric supernova explosion with a high ejection velocity Accepting 8 kpc as a minimum distance to Cir X-1 and 10^5 yr as the age[12] of G321 9−0 3, we see that the transverse component of the ejection velocity needs to be 500 km s^{-1} This is greater than the largest known pulsar velocity[20] (365 km s^{-1})

There are several future lines of investigation which could resolve some of the questions raised by Cir X-1 First, proper-motion studies in the radio domain (using VLBI techniques) and perhaps in the optical region could determine whether Cir X-1 was ejected from G321 9−0 3 If so the nebula around Cir X-1 could not itself be a supernova remnant We propose to undertake these studies using the Parkes-Tidbinbilla interferometer system Second, further mapping of the nebula could be undertaken to investigate more fully the absence of limb-brightening and the spectral index Finally, detailed theoretical modelling of the dynamics could yield an upper limit on the time for circularization of the eccentric orbit and thus yield an upper limit on the lifetime of the system

The MOST is operated by the University of Sydney under funding provided in part by the Australian Research Grants Committee, the University of Sydney Research Committee and the Science Foundation within the University of Sydney We thank Professor B Y Mills and Dr J M Durdin for help with using the MOST The research described in this paper was carried out in part by the Jet Propulsion Laboratory of the California Institute of Technology under contract to NASA

The historical record for Sirius: evidence for a white-dwarf thermonuclear runaway?

Frederick C. Bruhweiler*, Yoji Kondo† & Edward M. Sion‡

* Department of Physics, Catholic University of America, Washington, D C 20046, USA
† Laboratory for Astronomy and Solar Physics, NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771, USA
‡ Department of Astronomy and Astrophysics, Villanova University, Villanova, Pennsylvania 19085, USA

Schlosser and Bergmann[1] recently presented evidence that in medieval times Sirius was a bright red star, rather than the present bluish-white star, from which they have suggested that Sirius B is a recently born white dwarf. However, their model poses severe evolutionary problems. We present the results of our attempts to detect possible planetary nebula ejecta toward Sirius, using data obtained by the International Ultraviolet Explorer (IUE) satellite. Based upon these results and in the light of recent advances in understanding white-dwarf evolution, we propose that Sirius B underwent a recent thermonuclear runaway event, triggered by a diffusion-induced CN reaction, to explain the historical behaviour of this star.

Two evolutionary problems remain in the Schlosser and Bergmann evolutionary picture First, the implied cooling time for the white dwarf, Sirius B, is several orders of magnitude too short to be explained by current theories of white-dwarf cooling For example, current predictions indicate that the time required for a white dwarf with an effective temperature $\sim 2\ 7\times10^4$ K, like Sirius B (ref 2), to cool from 10^5 K, typical of a planetary nebula nucleus, is $\sim 10^7$ years To explain such discrepancies would require either new physics or a rethinking of our current picture of the later stages of stellar evolution Secondly, there is no evidence of any stellar ejecta, although such ejecta could have escaped detection A search for such ejecta is warranted, especially in view of recent analysis of ultraviolet spectral data obtained of the red-dwarf-white-dwarf binary system V471 Tauri[3], which showed possible gaseous material moving away from that system at $-590\ \mathrm{km\ s^{-1}}$

It is well known that interstellar ultraviolet absorption lines of cosmically abundant atomic species can provide a very sensitive means of detecting intervening gas Thus, in our search for the putative ejecta, we have made use of data previously acquired by the IUE These data come from the high-dispersion spectral image SWP 10075 obtained for the white dwarf Sirius B These data cover the spectral region from ~1,200 to 2,000 Å and provide information on many ground-state transitions for several cosmically abundant species A full discussion of the acquired data and a discussion of the observed interstellar features can be found elsewhere[4]

The new observational results that we present here represent a reanalysis of the IUE image SWP 10075 This reanalysis is necessary because originally we were not looking for possible high-velocity interstellar absorption, and we can now apply additional techniques to place stronger detection limits on intervening gaseous absorption by using the almost featureless nature of white-dwarf spectra

Our data analysis follows very closely that recently presented[3] We have taken wavelength regions containing the strongest transitions for the abundant atomic species and converted these data to the velocity frame by using the transformation $v = c\,(\lambda - \lambda_0)/\lambda_0$, because the internal wavelength (and velocity) scale of the IUE cameras is extremely accurate ($\pm 2\ \mathrm{km\ s^{-1}}$), absorption due to more than one ion at a particular velocity should be very closely reproduced at any velocity The interstellar features of C II, Si II and O I are seen near zero velocity, but there is no evidence of other features within $3{,}000\ \mathrm{km\ s^{-1}}$ of the rest velocity There was a hint of a feature at the 1 5 σ level near $-30\ \mathrm{km\ s^{-1}}$ with respect to the interstellar component in the Si II data, but nothing is seen in other ions Although planetary nebulae typically show expansion velocities $\sim 30\ \mathrm{km\ s^{-1}}$, the recent discovery of sharp high-velocity features in V471 Tauri justifies searching for components over a large velocity interval Because the species C II, Si II and O I have similar ionizations, we coadded these data in an attempt to enhance the detection limit in case weak high-velocity components of these ions existed We found no evidence of additional absorption other than the expected interstellar features The results of this coaddition are shown in Fig 1 The same test was also performed upon the stronger members of the resonance doublets for the highly ionized species N V, C IV and Si IV Again, no evidence of absorption was found either corresponding to the already observed low-ionization interstellar features or at higher velocities

Based on these results, we find it hard to support the supposition that the Sirius stellar system has recently ejected any type of detectable nebulosity or gaseous shell One might still argue that the velocity resolution ($22\ \mathrm{km\ s^{-1}}$) would not be sufficient if the expanding shell were 'masked' or unresolved from the intervening interstellar features However, the implied average particle densities toward Sirius are in accord with those found in other short lines of sight in the local interstellar medium[4,5] We derive from the IUE data an upper limit of $3\times10^{17}\ \mathrm{cm^{-2}}$ for the total gas column density for the putative ejecta about Sirius B If we assume an age of 1,000 years and an expansion velocity of $30\ \mathrm{km\ s^{-1}}$, we get a corresponding upper limit of $3\ 6\times10^{-5}\ M_\odot$ for the mass of any ejecta In addition, Copernicus results[6], with about a twofold better resolution and much better signal-to-noise ratio, do not indicate multiple interstellar Mg II features at 2,795 and 2,802 Å Thus, we must conclude that the physical mechanism causing the colour change of Sirius was due to a relatively quiescent process that did not involve any significant mass ejection

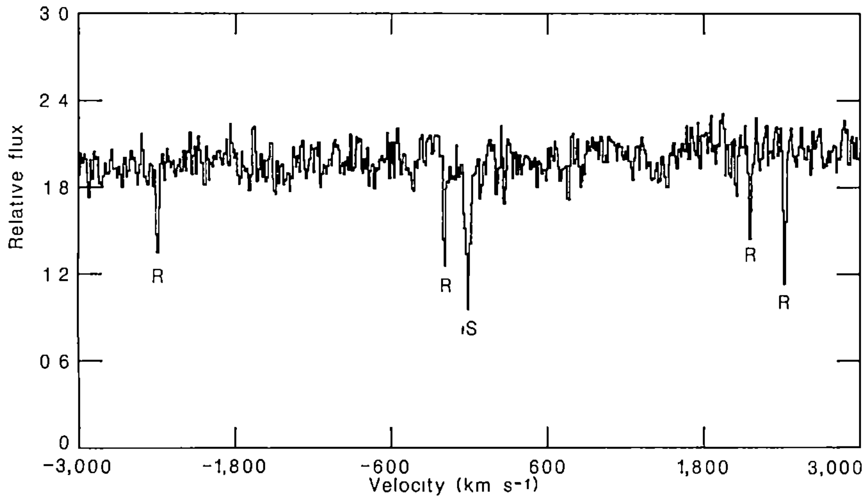

Fig. 1 Coadded data for regions corresponding to strong ground-state transitions of O I, C II and Si II. The coadded data for the O I 1,302.169, C II 1,334.532 and Si II 1,260.421 Å transitions are shown in the velocity frame. No evidence of absorption other than the expected interstellar contribution near zero velocity (labelled IS) is found. The other sharp features (R) are detector fiducial or réseau marks contributing from each of the data sets covering the respective atomic transitions. The data are from IUE image SWP 10075 acquired using the small aperture.

One other possible physical interpretation is that the red colour of Sirius during mediaeval times was due to intervening dust along the line of sight. Even though Sirius does not seem to have an infrared excess, at least two nearby A stars, Vega and Beta Pictoris, show strong evidence of possessing extended dust envelopes or disks[7–10]. The sizes of the dust particles in these disks are inferred to be large, possibly as large as 1 mm. These particles can provide extinction, but do not seem to yield any reddening at optical and ultraviolet wavelengths. Regardless of the properties of the dust, there cannot be reddening without extinction. To obtain an observed $B-V \geqslant 1.0$ as is deduced for Sirius in the sixth century would require substantial dimming. If we were to assume normal interstellar dust, Sirius would have been three magnitudes fainter than it appears today. it seems unlikely that Sirius would have attracted any particular attention as a bright star. In contrast, Schlosser and Bergmann find Babylonian sources that mention that Sirius was visible in the day time and must have been brighter than it is today. We must therefore find a more attractive explanation for the historical observations.

In recent years our picture of white-dwarf evolution has changed quite dramatically. There is now evidence that residual hydrogen burning is still occurring in hot-hydrogen-atmosphere (DA) white dwarfs like Sirius B. Recent theoretical efforts have demonstrated that nuclear shell burning, either by proton–proton reactions or by the diffusion-induced ^{12}C(p, γ)^{13}N can arise[11–13].

Burning by the ^{12}C(p, γ)^{13}N reaction is expected first to arise in DA white dwarfs like Sirius B ($T_{\rm eff} = 27{,}000$ K, where $T_{\rm eff}$ is the stellar effective temperature) once they have cooled to temperatures less than about 30,000 K (refs 11, 12). This hydrogen-burning occurs as the diffusion tail of the hydrogen layer extends downward into the underlying helium layer, where it encounters the diffusion tail of carbon extending upward from the ^{12}C–^{16}O core.

The great sensitivity of the CN reactions to temperature could lead to a thermonuclear shell flash. However, the thermal stability of diffusion-induced reactions in a 1.05 $M_\odot$ white dwarf like Sirius B has not yet been explored either with evolutionary-model calculations or by a linearized analysis of thermal stability. Here we extend the results of Iben and Tutukov[13] and Michaud and Fontaine[12], who discuss white dwarfs of 0.6 $M_\odot$ with ^{12}C–^{16}O cores, to the more massive Sirius B.

The model we present is that Sirius B did become a white dwarf some 10^7 years ago, as is generally accepted. However, it has cooled enough ($T_{\rm eff} < 30{,}000$ K) to initiate a thermonuclear runaway via the ^{12}C(p, γ)^{13}N reaction. It has been shown[14,15] that along its constant-radius cooling track where $\partial L/\partial M < 0$, a steadily burning white dwarf would be thermally unstable. In fact the steady-burning solutions show a high-luminosity stable branch and a low-luminosity unstable branch separated at the point of maximum $T_{\rm eff}$ (bifurcation point) in the Hertzsprung–Russell diagram or in the $M_{\rm e}$–$T_{\rm eff}$ plane, where $M_{\rm e}$ is the mass of hydrogen above the burning region (see Figs 2 and 3 in ref. 16).

It is well known that the long-term behaviour of evolutionary models of actual white dwarfs, even with the steady-burning assumption removed, is still morphologically similar to that of the solutions of the steady-burning model shown in Fig. 3 of Iben[16,17]. In other words, the evolution in the $M_{\rm e}$–$T_{\rm eff}$ plane as described in that figure is valid not only for accretion-induced thermal runaways, but also for a non-accreting star (or one with negligible hydrogen accretion compared with hydrogen lost by burning) experiencing a thermal runaway. The main effect of the hydrogen-burning runaway is to provide the energy necessary to allow the 'thin' hydrogen envelope to make a phase transition across a stability barrier from an unstable to a stable branch with very little change in the mass of the envelope.

Based on the above, we can describe the evolution of Sirius B during the proposed runaway event by applying the solutions or 'tracks' given by Figs 2 and 3 in Iben[16] for a 1.1 $M_\odot$ white dwarf. Therefore, if Sirius B did indeed undergo a thermal pulse, it then expanded to a giant structure, arriving on the stable branch, at a point determined by the mass of hydrogen lying above the burning region ($M_{\rm e}$). If, as we assume, $M_{\rm e} \simeq 10^{-4}$ $M_\odot$, Sirius B would have spent ~250 years mimicking a red giant, burning its envelope hydrogen stably along the plateau (stable) branch to the bifurcation point near maximum $T_{\rm eff}$. From that point, it would proceed to cool rapidly, on a thermal timescale, downward to lower luminosity along the unstable branch. For larger $M_{\rm e}$, longer times are spent on the stable branch. The expansion of Sirius B to a giant structure may have been accompanied by some mass loss but the higher thermal conductivity of a massive white dwarf such as Sirius B could have weakened the flash by the efficient conduction of energy below the burning region. Indeed, the upper limit (3.6×10^{-5} $M_\odot$) for the mass of the ejecta about Sirius B tends to support this interpretation.

The qualitative model presented here is speculative, but considering the growing evidence of the importance of nuclear burning in white dwarfs, plus the physical and observational constraints placed upon the white-dwarf cooling times, models of thermal runaways in white dwarfs offer the best means of describing the historical data for Sirius B. We cannot dispose of the possibility of a thermal runaway triggered by accretion, but the current environment of Sirius B implies low accretion rates both from Sirius A and the interstellar medium. In any event, the historical records may offer a unique observational opportunity to test current theoretical models for white-dwarf evolution.

Note added in proof. An article by H. Takeuchi *et al.* in *Newton* **4**, 138 (1984), mentions the Babylonian record of 700 BC, in which Sirius was observed as a red star. They consider the possibility that Sirius B was a red giant in 700 BC.

but dismiss the idea because a red giant would not have evolved fast enough to become a white dwarf in only 2000 years They speculate that Sirius B was a red giant tens of thousand years ago

Ice core record of the $^{13}C/^{12}C$ ratio of atmospheric CO_2 in the past two centuries

H. Friedli, H. Lotscher, H. Oeschger, U. Siegenthaler & B. Stauffer

Physics Institute, University of Bern, Sidlerstrasse 5,
CH-3012 Bern, Switzerland

The release of carbon into the atmosphere due to the activities of humans has caused an increase in concentration as well as a change in the isotopic composition of atmospheric carbon dioxide. CO_2 derived from fossil fuel combustion and from biomass destruction have $\delta^{13}C$ values of ~−25‰ (compared to the atmospheric value of ~−7‰) and are thus depleted in ^{13}C. We have measured $\delta^{13}C$ of CO_2 separated from air trapped in bubbles in ice samples from an ice core taken at Siple Station in Antarctica, in which it has been possible to demonstrate the atmospheric increase of CO_2 (ref. 1) and methane[2] with high time resolution. The isotopic results, together with the CO_2 record from the same ice core, yield information on the sources of excess carbon dioxide and provide a data base for testing the consistency of global carbon cycle models.

Prerequisites for obtaining a good ice core record of the recent past are a high accumulation rate which yields good time resolution, and the absence of summer melting (meltwater interferes with CO_2) Both conditions are fulfilled at Siple Station (75° 55′ S, 83° 55′ W) where the mean annual air temperature is −24 °C and the mean annual accumulation rate is 500 kg m^{-2} The ice core which we studied was cut during the Antarctic summer of 1983-84 to a depth of 200 m by the Polar Ice Coring Office (Nebraska) and the Physics Institute of the University of Bern Enclosure and age of the air have been discussed elsewhere[1,3] It has been possible to date the ice with an accuracy of ~±2 years down to a depth of 144 m (which corresponds to the year 1834) by counting seasonal variations in electrical conductivity[4] Below that depth, the core has been dated by extrapolation

The enclosed air is younger than the surrounding ice, because the enclosure of air in bubbles occurs only between depths of 64-76 m At shallow depths atmospheric air still circulates through the open pores In agreement with earlier papers[1,2], we adopted a value of 83 years for the age difference, and 22 yr for the width of the age distribution (time interval from 10-90% close-off of the total bubble volume)

The experimental procedure has been described previously[5,6] The air was extracted by grinding the ice samples (each ~700 g) at −20 °C in an evacuated container with a milling cutter The air escaping from the mechanically opened bubbles (~80 ml STP per sample) was collected by condensation at 14 K in a small steel cylinder Extraction efficiency is 80-90%, because not all bubbles are opened A small amount of the evolved gas was used for gas-chromatographic measurement of the CO_2 concentration (accuracy ~±3 p p m) CO_2 was quantitatively separated from the remainder of the sample by freezing it out at liquid nitrogen temperature in a metal vacuum line Isotope ratios were measured by mass spectrometry, and the results were corrected for the presence of N_2O which has the same isotopic masses (44, 45 and 46) as CO_2, following the procedure described by Mook and van der Hoek[7], which we checked and confirmed by analyzing artificial N_2O/CO_2 mixtures For $\delta^{13}C$ corrections, the N_2O concentration in the CO_2 sample was determined by mass-spectrometry from the abundance of mass 30, which corresponds to the fragment NO^+ produced in the ion source Details of this procedure will be reported in a separate paper We observed variable and significantly higher N_2O concentrations than expected Tests run afterwards showed that N_2O was produced in the vacuum line in a cold cathode manometer Accuracy of the $\delta^{13}C$ results is 0 10‰, as determined by analysing artificial CO_2-in-air-mixtures and from the scatter of the Siple results around a smooth line The accuracy of the calibration, as determined from analysing international isotope standards, is better than ±0 10‰

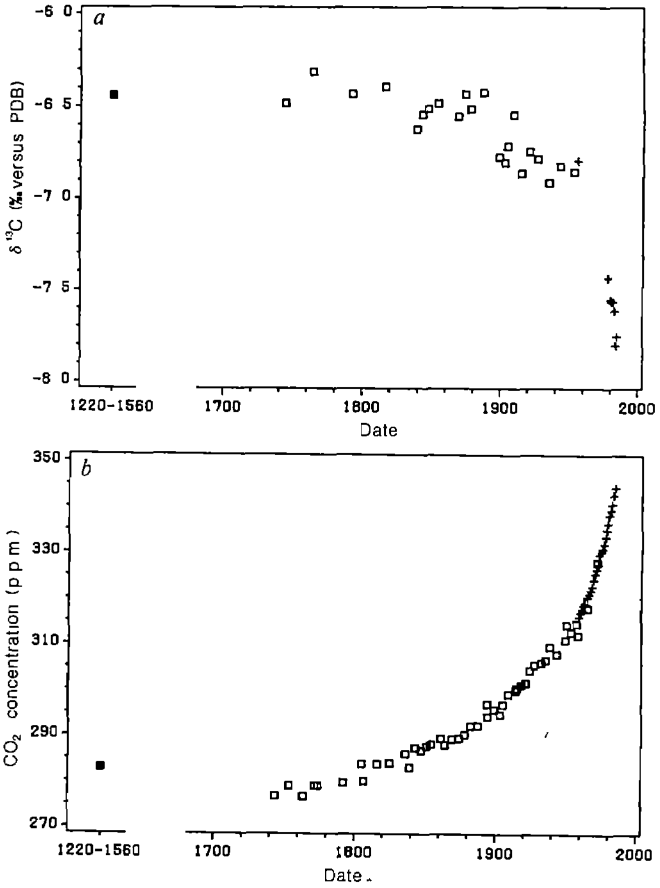

Fig 1 *a*, $\delta^{13}C$ of CO_2 (in ‰ versus PDB standard[18] N_2O-corrected), *b*, CO_2 concentration in air extracted from ice cores from Siple Station (open squares) (data from this work and ref 1) and from South Pole Station (black square)[6] Also shown (crosses) are results from direct atmospheric samples at Mauna Loa (refs 8-10 and C D Keeling, personal communication)

The $\delta^{13}C$ value and the concentration of CO_2 in the Siple ice samples are presented in Table 1 and Fig 1 For comparison, the average values for air extracted from an interval of a South Pole ice core which is between 430 and 770 years old[6], and results from direct atmospheric measurements at Mauna Loa (refs 8-10 and C D Keeling, personal communication) are also

Table 1 Analytical results of the Siple ice core

Average depth (m)	Gas age (yr AD)	Concentration (p p m)	$\delta^{13}C$ (‰, PDB)
187 70	1744	276 8	−6 48
177 50	1764	276 7	−6 31
168 30	1791	279 7	−6 43
154 89	1816	283 8	−6 39
142 75	1839	283 1	−6 62
140 75	1843	287 4	−6 54
138 20	1847	286 8	−6 51
134 47	1854	288 2	−6 48
126 80	1869	289 3	−6 55
123 80	1874	289 5	−6 43
121 80	1878	290 3	−6 51
116 82	1887	292 3	−6 42
110 20	1899	295 8	−6 77
108 80	1903	294 8	−6 80
107 20	1905	296 9	−6 71
105 25	1909	299 2	−6 54
101 80	1915	300 5	−6 86
98 80	1921	301 6	−6 74
95 17	1927	305 5	−6 78
90 77	1935	306 6	−6 91
86 80	1943	307 9	−6 82
81 22	1953	312 7	−6 85

shown in Fig 1 The average $\delta^{13}C$ value of the three samples from before 1800 (−6 41‰) is in excellent agreement with the mean value for the South Pole samples (−6 44 ± 0 03‰) This strengthens our confidence in the reliability of the experimental method We cannot exclude the possibility that the isotopic composition of CO_2 trapped in ice is shifted compared to the atmospheric value However, the agreement indicates that this is not the case, because isotopic fractionation processes active during trapping or storage of the air bubbles in ice could be expected to have different effects on the two cores which sample ice accumulated at different temperatures (the mean annual temperature is −24 °C at Siple Station, and −51 °C at the South Pole)

During the nineteenth and twentieth centuries, $\delta^{13}C$ slowly decreased, approximately antiparallel to the CO_2 concentration trend The youngest ice core data fit well the direct atmospheric observation in 1956 of −6 79‰ (results given in ref 8 and N_2O-corrected according to Mook and van der Hoek[7]) The overall decrease from the end of the eighteenth century to 1980 (−7 55‰ at Mauna Loa[9]) is −1 14‰ The estimated overall uncertainty of this figure is ±0 15‰, including a possible difference in calibration between the two data sets

The $\delta^{13}C$ record from the Siple ice core exhibits a step-like shift before 1900 and a plateau between ~1920 and 1950 There is also a less well pronounced plateau in the CO_2 results at the same depth It is premature at this stage to decide whether this actually reflects an accelerated atmospheric CO_2 and $\delta^{13}C$ change around the turn of the twentieth century, or whether it represents an artefact

The ice-core results can be compared with tree-ring $\delta^{13}C$ records, measured by a number of authors[11,12] Tree-ring $\delta^{13}C$ values generally exhibit considerable scatter, due to the fact that the $^{13}C/^{12}C$ fractionation varies from plant to plant as well as from year-ring to year-ring within a plant Different records, each an average over a number of trees, have yielded changes from 1800 to 1980 ranging from 0‰ (ref 11) to −2‰ (ref 12) Thus, it is difficult to compare those results with ours Stuiver *et al*[13] attempted to correct for variable physiological isotope fractionation by making use of a correlation between $\delta^{13}C$ and tree-ring area, and obtained a change of −0 8‰ from 1800 to 1980 Interestingly, many trees show constant (or even increasing) values in the period 1920 to 1950[12,14], which is also indicated by our results

The CO_2 results (Fig 1*b*) include, besides the IR laser absorption data of Neftel *et al*[1], additional results obtained by gas chromatography They indicate a pre-industrial (pre-1800) concentration of ~280 p p m , which is nearly equal, within a few p p m , to the average for the South Pole samples (283 ± 5 p p m , age interval 430–770 years) We therefore have no reason to assume any secular fluctuation exceeding 10 p p m between the years of 1200–1800

In order to compare the $\delta^{13}C$ and the CO_2 concentration results and to interpret these results in terms of CO_2 release rates into the atmosphere, it was necessary to use a model of the global carbon cycle[15,16] Within the framework of the carbon cycle model, the CO_2 and the $\delta^{13}C$ records from the Siple ice core are consistent, the calculated $\delta^{13}C$ trend (using the CO_2 concentration history of Fig 1*b* as model input) agrees well with the observations shown in Fig 1*a* Taking the Siple CO_2 and $\delta^{13}C$ records as model inputs, we calculated the release rates of CO_2 into the atmosphere The results depend on the structure of the oceanic and biospheric sub-models, but indicate that the cumulative non-fossil CO_2 production until 1980 was about half of the cumulative fossil production, and 50% or more of this non-fossil CO_2 was released prior to 1900

What additional information can be obtained from isotopic data that is not already contained in the CO_2 concentration record? Fossil and biospheric carbon both have very similar $\delta^{13}C$ values, but oceanic carbon is considerably richer in ^{13}C Thus, $\delta^{13}C$ can, in principle, be used to decide whether the non-fossil CO_2 input, as reconstructed from the concentration record, was of biospheric or of oceanic origin CO_2 escaping from the ocean is isotopically very similar to atmospheric carbon dioxide, so that input from the ocean would not have a significant effect on $\delta^{13}C$ values in contrast to input from the biosphere The difference in atmospheric $\delta^{13}C$ values between a biospheric and an oceanic CO_2 input depends on the input history As will be discussed in detail elsewhere[17], model calculations with the non-fossil input history back-calculated from the CO_2 record of Fig 1*b* yield a relatively small difference between biospheric and oceanic sources in the overall isotopic decrease This result can be understood by considering the different behaviour of CO_2 concentration and isotopic composition with respect to atmosphere–ocean interaction The oceanic uptake capacity for CO_2 is limited compared to that for isotopic perturbations by a chemical buffering mechanism, and an isotopic perturbation is additionally attenuated by exchange with the biosphere Thus, a large CO_2 release during the 19th century still significantly affects the present-day atmospheric CO_2 concentration, but not the $\delta^{13}C$ value In other words, $\delta^{13}C$ values integrate over a relatively short time and therefore, a $\delta^{13}C$ record can reveal the time variations of the CO_2 release rates in greater detail than a record of CO_2 concentrations For this reason, further ice-core measurements are required to establish the past atmospheric history of CO_2 concentration and of $\delta^{13}C$ values

We thank K Hanni for help with mass-spectrometric measurements and CO_2 extraction Supported by the Swiss NSF

Seasonal variation of methylarsenic compounds in airborne particulate matter

Hitoshi Mukai*, Yoshinari Ambe*, Tatsunori Mukut†, Kazuo Takeshita† & Tsuneo Fukuma†

* Chemistry and Physics Division, National Institute for Environmental Studies, Yatabe Tsukuba, Ibaraki, 305 Japan
† Saigo Health Center, Minato Saigo, Oki, Simane 685 Japan

Inorganic and organic arsenic compounds in nature are methylated by biological action and released into the air, forming trimethylarsine and dimethylarsine[1–5]. These compounds are oxidized in the air to dimethylarsinic acid and trimethylarsineoxide[6] and exist as particles[7,8]. In this study, we examine seasonal variations of methylarsenic compounds in airborne particulate matter to try to understand the characteristics of the methylation of arsenic in nature. In summer a high concentration of dimethyl and trimethyl forms of arsenic was observed, while in winter the levels were very low. This seasonal variation can be attributed to the different temperatures of the environment during these seasons The activation energy of methylation of arsenic was estimated to be ~12 kcal mol^{-1} from Arrhenius plots and can be used to predict the behaviour of these methylarsenic compounds, which are considered to form an important portion of the arsenic present in airborne particulate matter.

The natural methylation of arsenic has been reported in lakes, seas and soils[9–11] Challenger and Higginbottom[2] reported that bread mould produced trimethylarsine from inorganic arsenic Cox and Alexander[4] also showed that fungi in sewage could produce trimethylarsine from inorganic and methylarsenic compounds Dimethylarsine is synthesized by methanobacterium[3] These arsines are released from various environmental media and are present in air Johnson and Braman[7] detected both gaseous and particulate trimethyl and dimethyl forms of arsenic in the atmosphere The methylation of arsenic is thus important for determining the mobility of this element in nature However, biological methylation in nature is not well understood because the concentrations of these methylated compounds in the air are very low Methylarsenic compounds, for example, are oxidized in the air and converted to particulate form (trimethylarsineoxide and dimethylarsinic acid)[6] Therefore, concentrations of these compounds in airborne particulate matter reflect the activity of biomethylation in nature

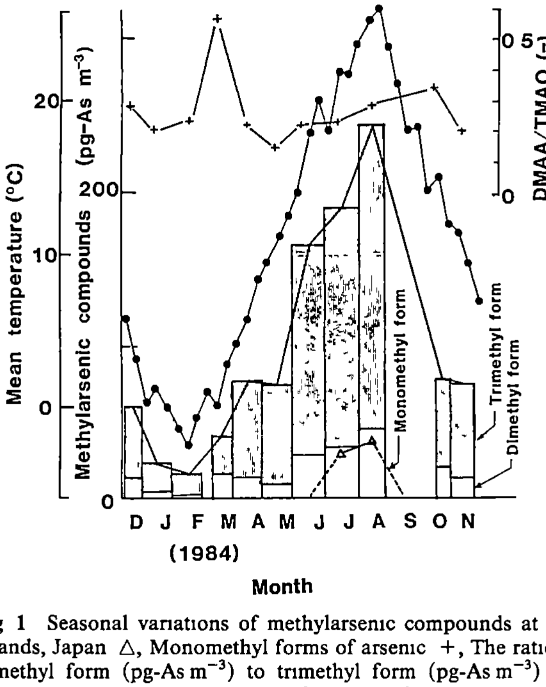

Fig 1 Seasonal variations of methylarsenic compounds at Oki Islands, Japan △, Monomethyl forms of arsenic +, The ratio of dimethyl form (pg-As m^{-3}) to trimethyl form (pg-As m^{-3}) ●, Mean temperature of every 10 days

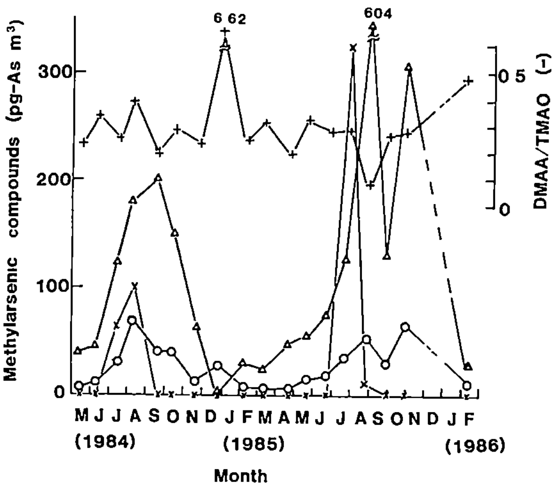

Fig 2 Seasonal variations of methylarsenic compounds at Tsukuba, Japan △, Concentration trimethyl, ○, dimethyl, ×, monomethyl forms of arsenic +, The ratio of dimethyl form to trimethyl form

Sampling of airborne particulate matter was carried out over 1 year at two sites in Japan, Oki Islands (an unpolluted area) in the Japan Sea and Tsukuba (a rural inland area) These two sampling sites are ~1,000 km apart The sampling at Oki Islands was carried out over 1 month with a low volume air sampler at the top of a mountain (200 m) (December 1983–November 1984) The samples from Tsukuba were collected with a high-volume air sampler for 3 days each month (May 1984–February 1986) Quartz fibre filters (PALLFLEX 2500QAST) were used, loaded filters were preserved in a store room at −20 °C

The hydride generation method proposed by Braman *et al*[7,12] was adapted to analyse the methylarsenic compounds in airborne particulate matter Dimethyl and trimethyl forms of arsenic (possibly dimethylarsinic acid and trimethylarsineoxide) were extracted from the filter with 10 cm^3 of 1 M HCl+0 02 M EDTA (9 1) and reduced with 6 cm^3 of 10% $NaBH_4$ in 1M HCl containing 20 μmol EDTA The arsines produced were trapped in a half-packed U-tube dipped in liquid nitrogen Following gas chromatography, each arsine separated was detected as arsenic by atomic absorption spectroscopy The details of this method are described elsewhere[13] The detection limits of monomethyl, dimethyl and trimethyl forms of arsenic by this method were ~2 pg-As m^{-3}

Figure 1 shows the variations of methylarsenic compounds in airborne particulate matter sampled at Oki Islands High concentrations of dimethyl and trimethyl forms were observed in summer The pattern of the seasonal changes of the concentrations of dimenthyl and trimethyl forms was found to correlate with the mean temperature The order of these concentrations was similar to that reported by Johnson and Braman[7] The ratio of the dimethyl form to trimethyl form was 0 15–0 34 in most cases, indicating that trimethylarsine was the dominant form of methylated arsenic produced by biomethylation Traces of the monomethyl form were detected in the July and August samples

Although the ratio of these methylarsenic compounds to inorganic arsenic in airborne particulate matter was <10%, the contribution of methylated arsenic cannot be ignored, because the concentration of methylarsenic compounds in airborne particulate matter often amounted to 18 p p m whereas the concentration of arsenic in the Earth's crust is 2 p p m

Figure 2 illustrates the seasonal variations of methylarsenic compounds at Tsukuba Although the two sampling sites are

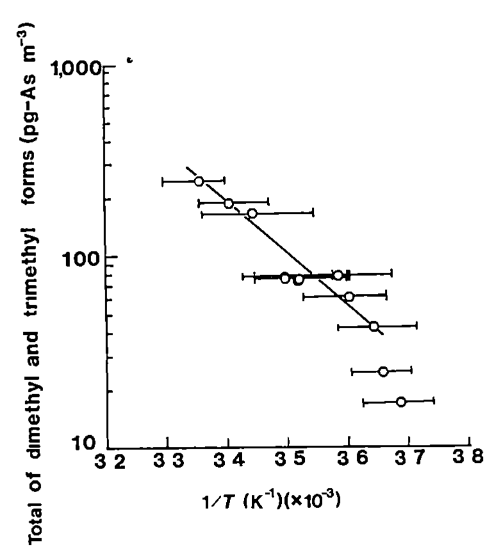

Fig 3 Arrhenius plot using the total concentration of the dimethyl and trimethyl arsenic compounds in the air (particulate form) at Oki Islands The line was drawn using nine points, and disregards two winter points, when snow covered the land surface The horizontal line of each point indicates the range between the mean value of maximum and minimum temperature

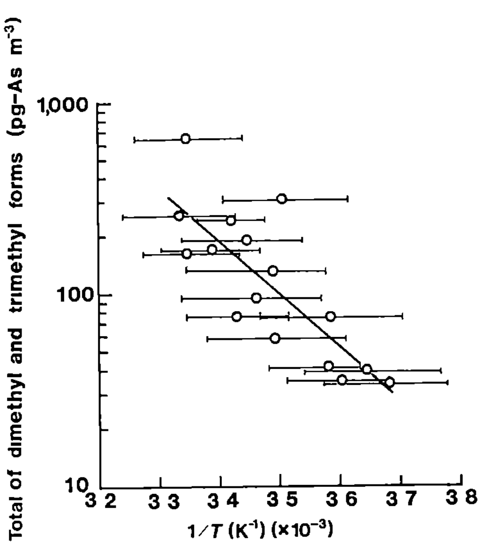

Fig 4 Relation between the total of the concentrations of the dimethyl and trimethyl arsenic compounds (particulate form) at Tsukuba The line obtained from Fig 3 is shown The horizontal line at each point indicates the range between maximum and minimum temperature during the sampling period

far apart from each other, the patterns of the variation and the concentration of the methylarsenic compounds were very similar in Oki Islands and Tuskuba At both locations the concentrations of dimethyl and trimethyl forms were high in summer, but low in winter The monomethyl form, which was detected in the summer samples at Oki Islands, was also detected only in the July and August samples, and was considered to be caused by contamination with a pesticide[14] (iron methane arsonate) spread over rice fields 20-30 km away from the sampling site, not biomethylation Therefore, we shall not consider this form in the following discussion

The seasonal variations of the dimethyl and trimethyl forms of arsenic can be attributed to the change of temperature of the environment Tanaka *et al*[8] reported that a high concentration of dimethylarsenic compound in airborne particulate matter was observed during the summer In the case of methylation of selenium, Chau *et al*[15] pointed that the production of volatile selenium was also temperature dependent Figure 3 shows the relation between the total dimethylarsenic and trimethylarsenic concentrations (mean concentration for ~1 month) at Oki Islands and the reciprocal of the mean temperature of the sampling period If we assume that arsines diffuse into the atmosphere faster than their rate of production, and are oxidized constantly, the concentration of these compounds is considered to reflect the rate of production of methylarsenic compounds, and the activation energy of biomethylation of arsenic in nature is estimated to be 12 kcal mol^{-1} from the slope of the graph (avoiding the two winter samples, using all the points gives a value of ~16 kcal mol^{-1}) This value is consistent with those of general biological reactions (8-18 kcal mol^{-1}) But, as biomethylation is influenced not only by temperature but also by other factors such as humidity[11,16] and the concentration of these compounds in air is affected by meteorological conditions (such as mixing depth, wind speed and weather), the activation energy obtained is considered to be the apparent value It will reflect various environmental factors, even though temperature is a major factor For example, if the rate that the arsine gas is oxidized and converted to the airborne particulate matter is faster in summer, the slope of the line of the Arrhenius plot will be overestimated compared with the real value, whereas the existence of a surface inversion layer in winter might make the concentration of airborne particulate matter relatively higher and lead to an underestimation of the activation energy The effect of an inversion layer may be minor, because the sampling site is located on top of the mountain (200 m) Further study will be necessary in order to understand the conversion rate, which includes the rate of heterogeneous reaction between arsine gas and airborne particulate matter as well as the rate of homogeneous oxidation reaction with oxygen[6], peroxides and hydroxyl radicals

Figure 4 shows the data from Tsukuba Many points were distributed along the line drawn from the data in Fig 3, indicating that a similar activation energy can be obtained even though the sampling sites are different The deviation of two points from the line suggests that the data obtained during short-period sampling is strongly influenced by the meteorological conditions at the time and that the line does not describe the maximum concentration corresponding to each temperature

Our data showed that the methylation of arsenic in nature is an important source of arsenic in the air and is influenced by temperature The activation energy estimated above can be used to predict the behaviour of methylarsenic compounds in the air throughout the year, although it is not known to which methylation reaction this value corresponds These findings do not give any new insight into biological methylation, however, they give important information concerning the contribution of biomethylation to the geological cycles of trace elements (As, Se and so on) The data shown here were only from the particulate form, the gaseous form of trimethylarsine needs further investigation The measurements of the change of the rate of the production of methylarsenic compounds with the temperature of variables such as the land surface, which is one of the most probable sources of methylarsenic compounds, are also needed for comparison with the obtained activation energy

We thank members of Saigo Health Center and NTT (Saigo) for the field assistance, Dr T Uehiro, Dr M Morita and Dr Y Yokouchi for useful advice

Reversed magnetization in pyroclastics from the 1985 eruption of Nevado del Ruiz, Colombia

Tenerife, Canary Islands, Spain

One of the fundamental principles of palaeomagnetism and rock magnetism states that the direction of natural remanent magnetization (NRM) is acquired parallel to the applied field. However, ferromagnetic mineral phases with complex microstructures may violate this rule[1,2] and produce a magnetization vector which is antiparallel to the direction of the external field. Andesitic pumice, which was hurled several kilometres during the disastrous 1985 eruption of the Nevado del Ruiz volcano (Colombia), carries a stable but reversed NRM with southerly declination and negative inclination. Heating experiments show that this magnetization is due to a self-reversal mechanism which also induces a reversed thermoremanent magnetization (TRM) in the laboratory field. Thus we have used the Nevado del Ruiz 1985 pumice, which was magnetized in the present well-known geomagnetic field, to demonstrate for the first time that self reversal has actually controlled the process of NRM acquisition.

The Nevado del Ruiz, a stratovolcano of the Ruiz-Tolima complex in the northernmost part of the Andean Cordillera (lat 4°53′ N, long 75°10′ W, altitude 5,400 m, regional geomagnetic field inclination +31°), covered by a 17 km^2 ice cap, has had two major eruptions in 1595 and 1845, and its last explosive eruption was on 13 November 1985 (ref 3) Lithic fragments, ash, and juvenile scoria and pumice fragments were emitted during the last eruption and an eruptive column up to $\sim$5,600 m in height was formed Most of the hot juvenile eruptive products fell on the ice cap The catastrophic mudflow thus generated travelled down the radial river valleys causing the death of 25,000 people and damage assessed at US$ 300 million

Dacitic andesite pumice fragments were spread around the emission centre in the form of pyroclastic falls Some of the fragments were embedded in the mud as they fell, or penetrated cushions of the *Plantago rigida* vegetation Where they lodged, moderate thermal effects were observed in smashed plant fragments

To investigate the temperature of deposition of this pumice, hand samples of encrusted fragments (5-10 cm in diameter), oriented with a magnetic compass, were collected within a radius of 5-6 km from the emission centre The oriented samples were collected over a 3-week period after the 13 November eruption by one of us (J C C), who formed part of the Scientific Commission sent by the Spanish Ministry of Foreign Affairs to collaborate in the study and surveillance of the Nevado del Ruiz volcano

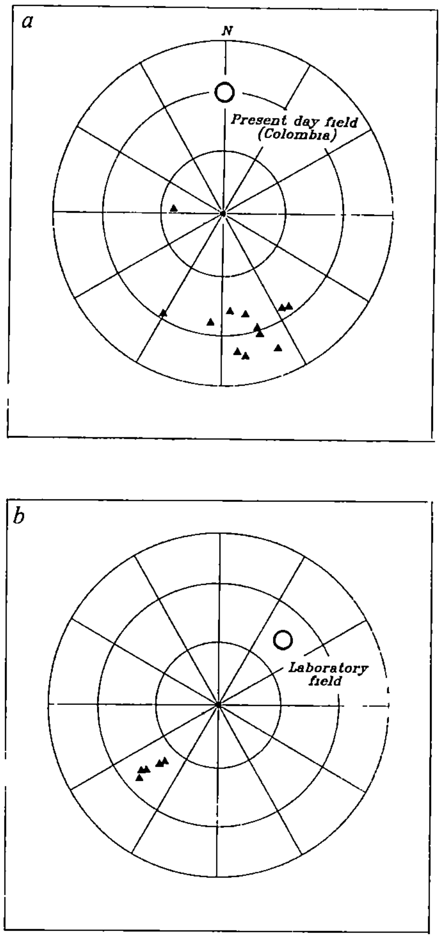

Fig. 1 Directions of *a*, natural remanent magnetization (NRM), mean direction declination = 170 7°, inclination = −35 9°, α_{95} = 14 2, 12 samples plotted *b*, Laboratory-induced thermoremanent magnetization (TRM), mean direction declination = 226 6°, inclination = −44 7°, α_{95} = 6 3, 5 samples plotted Plots are stereographic projections together with applied field directions Field and magnetization vectors are antiparallel ○, Lower, ▲, upper hemisphere

The result of the initial magnetic remanence measurements is shown in Fig 1 All samples carry a reversed NRM which—within statistical error—is antiparallel to the present field of the region Alternating field (AF) demagnetization reduces the directional scatter that results from small orientation inaccuracies and from additional magnetization components of normal polarity and of spurious direction The main reversed NRM component is stable up to 80 mT and has median destructive fields between 10 mT and 30 mT

When the NRM vector is measured during repeated heating and cooling cycles at variable temperatures in air and in zero field[4], a polarity change is registered at temperatures $\sim$120 °C (Fig 2), the strong reversed room temperature component being completely removed at 150-160 °C Above these temperatures the NRM polarity is always normal (parallel to the present field) When cooling back to room temperature after the first heating cycle, the reversed component develops again in several samples (Fig 2*a*) Thus, the reversal mechanism is still active in these laboratory conditions On heating to higher temperatures the normal NRM component disappears between 350 and 400 °C

Two optically homogeneous magnetic mineral phases of different colour and reflectivity are observed using the ore microscope A brownish, low reflectivity but strongly magnetic phase is attributed to titanomagnetite A whitish-yellow, higher reflec-

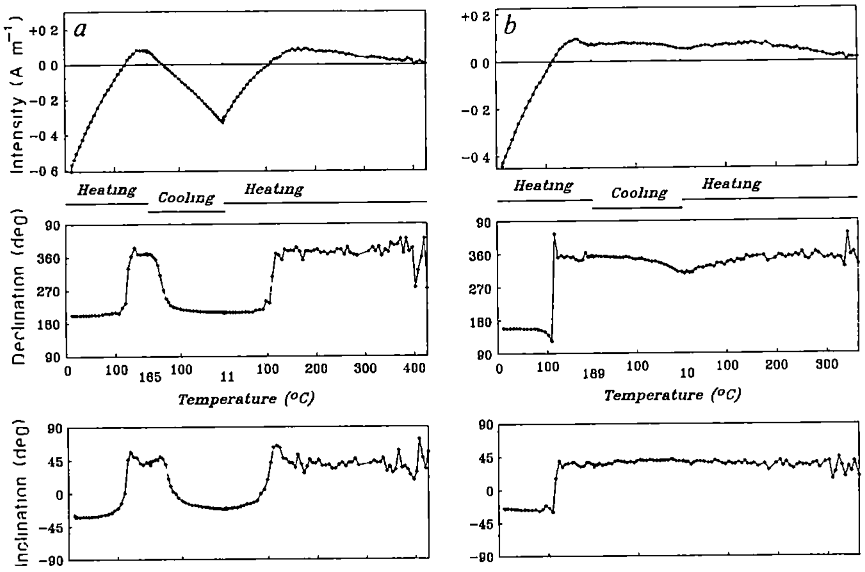

Fig. 2 Inclination, declination and intensity of natural remanent magnetization of two pyroclastic samples during thermal treatment in air and zero magnetic field Heating rate 10 °C min^{-1} *a*, The NRM direction reversibly changes polarity and NRM intensity changes sign at ~120 °C on first heating to 165 °C, during subsequent cooling to room temperature and in the second heating cycle up to 425 °C This indicates that a self-reversal process was active during initial NRM formation *b*, After removal of the reversed component during the first heating cycle up to 189 °C, only a normal NRM component is observed in the subsequent cooling and heating cycles Note that the temperature scale has been folded around the maximum temperature of the first heating cycle and the minimum temperature of the subsequent cooling cycle

tivity mineral which is less magnetic but mechanically very hard and is always closely associated with the titanomagnetite, is identified as ilmenohaematite An appreciable titanium content in these oxides is suggested by the intermediate Curie temperatures which were found to be between 370 and 410 °C for the major component of the saturation magnetization and between 180 and 200 °C for the minor component

Both magnetic phases are extraordinarily resistant to oxidation during thermal treatment in air, as indicated by complete reversibility of strong field magnetization behaviour up to temperatures >600 °C Therefore, a TRM was given to some samples between 450 °C and room temperature in the presence of a laboratory field of the same magnitude as the present geomagnetic field in Colombia (Fig 1*b*) The TRM vector acquired again has opposite polarity to the applied field and this must be due to self reversal AF cleaning of this TRM shows that a normal component with low coercivity and small magnitude (up to 30% of the reversed component) is superimposed NRM- and TRM-intensities are equal after AF demagnetization at a field strength of 10 mT and demonstrate that the NRM was acquired as a TRM over the temperature range mentioned In accordance with observations reported from the explosion[3], this points to a hot emplacement of the pumice bombs at temperatures higher than the maximum Curie temperatures

The evidence that oppositely directed NRM directions are caused by frequent polarity reversals of the geomagnetic field is overwhelming Nevertheless, the occurrence of self reversal of NRM in igneous rocks may be underestimated To qualify NRM directions as being parallel or antiparallel to the magnetizing field, much more detailed and time consuming experiments have to be conducted than those which are usually performed during routine palaeomagnetic measurements Therefore, a substantial amount of self reversals may have been overlooked in the past Possibly some of the abnormal NRM polarities in Mankinen and Dalrymple's[5] polarity record for the past 5 Myr may be due to self-reversing basalts

The physical models of self reversal can be divided into two categories single-phase and double-phase models The sign of spontaneous magnetization in Néel's[6] N-type ferrites may change at a specific temperature due to different temperature dependence of the sublattice magnetizations Negative magnetic coupling between two phases may result from magnetostatic or exchange interaction All these mechanisms have been observed to act on the TRM of certain igneous rocks[7-11]

The self-reversal mechanism of the Nevado del Ruiz 1985 pumice is not yet fully understood The one-phase model, however, can be excluded because the temperature dependence of saturation magnetization shows normal behaviour A negative coupling between the two visible ore phases seems to be unlikely because the continuous demagnetization experiments (Fig 2) show the reversibility of the self-reversal effect in laboratory conditions to be very sensitive to the maximum demagnetization temperatures between 160 and 190 °C The higher the temperature is raised in this temperature interval, the more suppressed is the self-reversal effect Possibly two intimately mixed, chemically very similar phases within the lower Curie-point phase are interacting If a high enough temperature is reached, the normally magnetized phase with slightly higher Curie temperature becomes demagnetized so that on cooling in zero field no interaction takes place with the other phase of slightly lower Curie temperature Both phases remain demagnetized on recooling to room temperature and the remaining remanent magnetization originating from the high-Curie-point phase has normal polarity (Fig 2*b*) Such a mechanism would closely resemble the exchange interaction model developed by Uyeda[10]

The major significance of the self-reversal observed in the Nevado del Ruiz 1985 pumice, however, lies in the clear evidence that this mineralogical mechanism has indeed controlled the polarity of the NRM when the rock formed

Geochemical correlation between southern African kimberlites and South Atlantic hotspots

Anton P. le Roex

Department of Geology, University of Cape Town, Rondebosch,
7700 South Africa

Recent isotopic and trace element data[1,2] have led to the subdivision of southern African Cretaceous/Jurassic kimberlites into group I and group II varieties. The former have Sr, Nd and Pb isotopic signatures similar to those commonly associated with ocean island basalts and are thought to derive from within the asthenosphere[1]. The high Sr and low Nd and $^{206}Pb/^{204}Pb$ isotopic ratios of group II kimberlites have been cited as evidence that these kimberlites are derived from a source within the sub-continental lithosphere[1,3]. Basalts erupted at the surface expression of South Atlantic hotspots preserve isotopic and trace element ratios similar to those of group I and group II kimberlites. Hotspots falling within the Dupal anomaly[4] have similar characteristics to group II kimberlites and those outside the Dupal anomaly to group I kimberlites. This correlation raises the possibility that the source region of southern African group II kimberlites is also located within the asthenosphere (within recycled lithospheric material) and not necessarily within the sub-continental lithosphere.

Southern African Cretaceous/Jurassic kimberlites comprise two dominant petrographic and geochemical varieties, namely so-called micaceous (group II) and basaltic or non-micaceous (group I) kimberlites[1,5]. Both types contain diamonds, appear to be distributed throughout the Kaapvaal craton and show a broad age correlation with group I kimberlites (80–114 Myr), being generally younger than group II kimberlites (114–200 Myr)[1,6]. Group I kimberlites have significantly lower $^{87}Sr/^{86}Sr$ and Rb/Sr ratios and higher $^{143}Nd/^{144}Nd$, $^{206}Pb/^{204}Pb$ and U/Pb ratios than group II kimberlites[1-3,5,7].

Smith[1] has argued that these geochemical differences are not a result of alteration and/or crustal contamination but reflect substantial chemical differences in their mantle source regions. The slightly depleted source region signature of group I kimberlites, relative to bulk Earth, has been cited as evidence for an asthenospheric origin (their isotopic characteristics are similar to most ocean island basalts). In contrast, the enriched source region signature of group II kimberlites has been used to argue for an origin within the ancient enriched sub-continental lithosphere[1-3].

Hart[4] has recently delineated a major region between southern Africa and South America that forms part of his proposed Dupal anomaly, in which the isotopic signature of hotspot lavas is distinct from those occurring to the north of ~20° S and to the south of ~43° S. More recent data (S. R. Hart, unpublished data) shows that in the South Atlantic this anomaly extends as far south as the recently documented Shona hotspot at ~54° S[8,9]. Basalts that have erupted at hotspots within the Dupal region have Sr and Nd isotopic ratios enriched compared with the bulk Earth and have higher $^{207}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ ratios than most other oceanic volcanics. Here I compare the isotopic and trace element 'signatures' of South Atlantic hotspots and southern African kimberlites.

Basalts from the South Atlantic describe two distinct trends in terms of Zr/Nb ratio versus $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ ratios (Fig. 1). The more radiogenic Sr and less radiogenic Nd trends for a given Zr/Nb ratio correspond to basalts erupted within the Dupal anomaly and comprise the hotspots of Gough, Discovery and Tristan da Cunha and MORB in the vicinity of the Shona hotspot and, by implication, the as yet unsampled Shona hotspot[8]. The lower trend in each diagram includes the hotspots of Bouvet, Marion and Ascension and MORB from the vicinity of the Bouvet hotspot. It is evident from Fig. 1 that group I kimberlites plot on the extension of the 'Bouvet' trend whereas group II kimberlites plot on the extension of the Dupal trend.

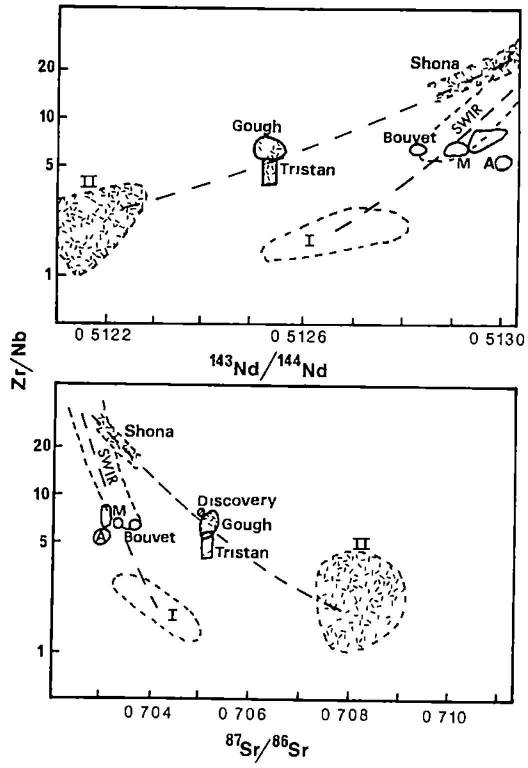

Fig. 1 Correlation between Zr/Nb ratio and $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ ratios in South Atlantic basalts and group I and group II kimberlites. Initial isotope ratios of the kimberlites have been used for plotting. SWIR, Southwest Indian Ridge, II, group II kimberlites, I, group I kimberlites, A, Ascension, M, Marion (two fields). Sources of data refs 1, 3, 8, 19, 25–28, 31, 34, S. R. Hart (unpublished data) and A. P. le R. (unpublished data).

A similar correlation exists for incompatible trace element variations. Figure 2 shows the variation of Ba/Nb, Zr/Nb and La/Nb ratios in MORB, South Atlantic hotspot basalts and group I and group II kimberlites. Hotspots within the Dupal anomaly (that is, Gough, Discovery, Tristan da Cunha and the associated Walvis Ridge and Rio Grande Rise) are characterized by high Ba/Nb (8–22), La/Nb (0.75–1.25) and low Zr/Nb (<10) ratios and define a trend extending away from the field of Bouvet, Marion and other non-Dupal-area hotspots towards group II kimberlites (Ba/Nb > 15, La/Nb > 1, Zr/Nb < 3). Although data are not yet available from the Shona hotspot, the high Ba/Nb ratios of associated southern Mid-Atlantic Ridge enriched MORB (Fig. 2) indicates that this hotspot is also likely to be characterized by high Ba/Nb ratios. Group I kimberlites, on the other hand, have low Ba/Nb (<8), La/Nb (<0.8) and Zr/Nb (<4) ratios, similar to those of the non-Dupal hotspots Bouvet, Marion and Ascension (Ba/Nb < 9, La/Nb < 0.6 and Zr/Nb < 10). Depleted MORB in these diagrams defines a very distinct trend extending towards high Zr/Nb (>20) and La/Nb (>1.0) ratios at low (<7) Ba/Nb ratios.

Figure 3 extends this correlation between group II kimberlites and South Atlantic Dupal hotspot volcanics to include Pb isotopes. It is evident that these lavas all plot on a sub-parallel Pb isotope array characterized by low $^{206}Pb/^{204}Pb$ and high $^{208}Pb/^{204}Pb$ and (excluding Tristan da Cunha) $^{207}Pb/^{204}Pb$ ratios relative to MORB, non-Dupal-area hotspot volcanics and group I kimberlites. The high ^{208}Pb and ^{207}Pb of enriched southern Mid-Atlantic Ridge basalts (Fig. 3, S. R. Hart, unpublished data) associated with the Shona hotspot indicate that the latter is likely to have Pb isotopic signature similar to that of Gough

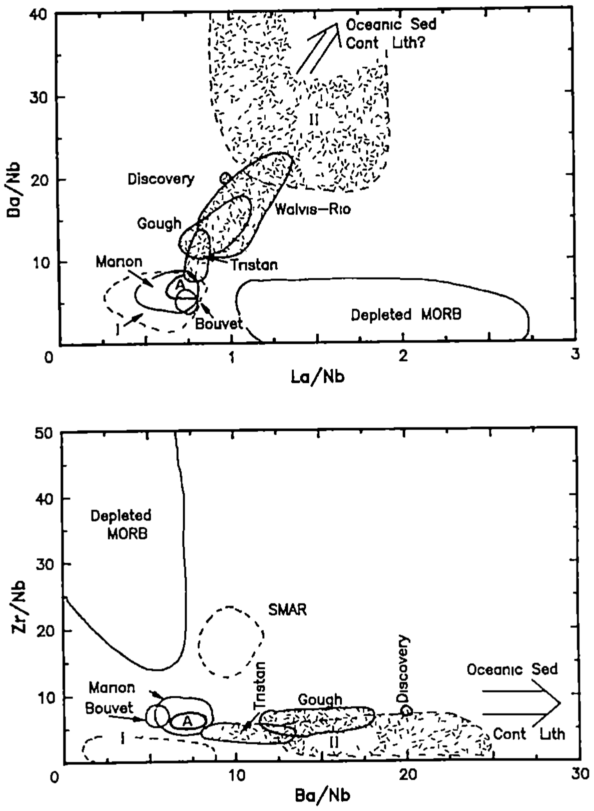

Fig 2 Covariation of Ba/Nb, Zr/Nb and La/Nb ratios in South Atlantic basalts and group I and group II kimberlites Compositions of oceanic sediment[19] and sub-continental lithosphere[26] are shown for comparison Walvis-Rio, Walvis Ridge and Rio Grande Rise, SMAR, southern Mid-Atlantic Ridge, other abbreviations as in Fig 1 Data from refs 3, 10, 19, 25, 26, 31-34 and A P le R (unpublished data)

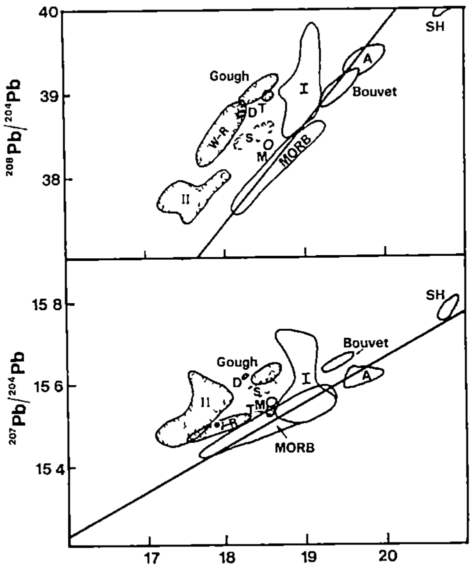

Fig. 3 Pb isotope variation in South Atlantic basalts, group I and group II kimberlites and MORB Initial isotopic ratios of the kimberlites have been used for plotting NHRL, Northern Hemisphere reference line[3], D, Discovery, T, Tristan, SH, St Helena, other abbreviations as in Figs 1 and 2 Data from refs 1, 2, 19, 21 and S R Hart (unpublished)

Zr/Nb, Ba/Nb and La/Nb are highly incompatible trace element ratios that are not normally fractionated during partial melting processes However, the very low degrees of partial melting possibly associated with alkaline, and particularly kimberlite, magma generation require that some caution be exercised when interpreting variations in such inter-element ratios Nevertheless, the good correlations exhibited between these ratios and Sr, Nd and Pb isotopic ratios suggest that the variations shown in Figs 1 and 2 reflect source region composition and are not primarily due to variations in degree of partial melting or residual source mineralogy

Although the trends depicted in Fig 1 correspond broadly to mixing between a depleted MORB-type reservoir and highly enriched reservoirs (reflected by group I and group II kimberlites as possible end-members), Figs 2 and 3 negate any simple mixing relation between the Dupal hotspot-group II kimberlite trend and a depleted MORB-type source Even within the Dupal hotspot-group II kimberlite trend, relations are complex and there is, for example, no simple correlation between ^{87}Sr/^{86}Sr and ^{206}Pb/^{204}Pb along the Pb-Pb arrays[4]

Before evaluating possible implications of the geochemical correlations shown in Figs 1-3, it is necessary to consider current models for the origin of hotspot volcanism Allègre and Turcotte[11] recently summarized current ideas on hotspot source regions and have proposed an integrated model which recognizes two 'end-member' hotspot types The first derives from upwelling of primordial or near-primordial mantle across the asthenosphere-mesosphere boundary, the second from upwelling from a 'mesosphere boundary layer' of recycled (subducted) oceanic lithosphere including pelagic sediments[12,13] and/or delaminated sub-continental lithosphere[14] Delaminated lithosphere may alternatively occur as 'rafts' within the asthenosphere rather than as a boundary layer[15] Evidence for a primordial source component derives mainly from the high ^{3}He/^{4}He isotopic ratios associated with hotspots such as Hawaii and Iceland[16], and evidence for a recycled component derives from the higher ^{208}Pb/^{204}Pb and ^{207}Pb/^{204}Pb ratios and low ^{3}He/^{4}He ratios of hotspots such as Gough and Tristan da Cunha[11,16] The sub-parallel Pb isotope array of Dupal hotspots also requires that the recycled material composing this mesospheric boundary layer is ancient (>1 Gyr)[4,11]

In the South Atlantic, Bouvet (with a high ^{3}He/^{4}He ratio[17]) can be regarded as an example of a hotspot with a significant primordial component in its source region[18], whereas Gough, Tristan da Cunha, Discovery and Shona appear to be hotspots with a major recycled component in their source regions[11,16,18,19] This interpretation is also consistent with the trace element variations shown in Fig 2, where Gough, Tristan and Discovery define a trend extending away from compositions typical for normal ocean island basalt (containing a major primordial component), such as Bouvet, Marion and Ascension, towards high Ba/Nb and La/Nb ratios characteristic of recycled oceanic lithosphere plus sediment or of sub-continental lithosphere[20,21]

Trace element and isotopic variations in South Atlantic hotspots therefore suggest that the Dupal anomaly reflects an area where ancient recycled material exists within the asthenosphere Upwelling from this material has resulted in hotspot volcanism with an apparent lithospheric signature, whereas upwelling outside this region has led to hotspot volcanism with a more normal ocean island basalt signature

It is remarkable that in all three figures (Figs 1-3), group I and group II kimberlites plot either at the end of, or are superimposed on, the non-Dupal hotspot and Dupal hotspot trends respectively Group I and group II kimberlites therefore appear to be derived from source regions similar to the enriched components invoked respectively for non-Dupal and Dupal hotspots In group II kimberlites and Dupal hotspots this component has distinctively low ^{206}Pb/^{204}Pb and high ^{208}Pb/^{204}Pb, Ba/Nb and La/Nb ratios In group I kimberlites and non-Dupal hotspots this component has high ^{206}Pb/^{204}Pb and low Ba/Nb and La/Nb ratios

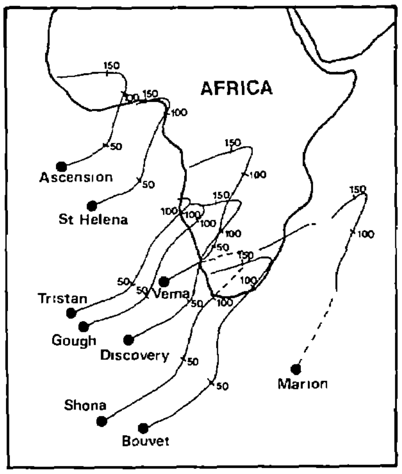

Fig 4 Diagram modified from ref 30 showing South Atlantic hotspots and their predicted palaeo-tracks The Shona hotspot and associated track is from ref 9 Numbers on tracks show ages in Myr

Two separate source regions therefore occur within the asthenosphere beneath the South Atlantic capable of generating alkaline volcanism with essentially the same distinct geochemical signatures as shown by group I and group II kimberlites We may extend this observation to recent plate-tectonic models advocating a correlation between the palaeo-position of hotspots and kimberlite magmatism[22-24]

The African plate contains many hotspots, several of which appear to record the entire history of the opening of the South Atlantic (Fig 4) On the basis of plate reconstructions, Cretaceous and Jurassic kimberlites in southern Africa have been explicitly related to the Bouvet and 'Meteor' (recently relocated and renamed Shona[9]) hotspots[23,24] Geochemical evidence presented here is consistent with such a model in that upwelling from these (or related) hotspots, when located beneath southern Africa (Fig 4), could lead to the deep-seated melting and subsequent eruption of kimberlite magmas with inherently different geochemical signatures, reflecting those of their respective source regions Kimberlites derived from upwelling associated with the Bouvet (or similar) hotspot would have group I geochemical characteristics, whereas those derived from upwelling associated with the Shona (or similar) hotspot would have group II characteristics In this regard, note that kimberlites in Ghana, Guinea and Sierra Leone have group I characteristics, which is consistent with their location on the palaeo-track of the Ascension hotspot (J J Gurney, personal communication, Fig 4), which has essentially the same trace element and isotopic signature as Bouvet (Figs 1-3)

Recent plate reconstructions[9,30] are consistent with a relationship between the Shona hotspot and group II (114-150 Myr) kimberlites but are not readily compatible with a simple relationship between Cretaceous group I kimberlites and the Bouvet hotspot (Fig 4) Group I kimberlites are too young to be directly associated with Morgan's[30] Bouvet palaeo-track and it is possible that in a more complex model, refinements to the plate-tectonic reconstructions, or the presence of an unrecognized non-Dupal hotspot located to the north-east of Bouvet will be required to resolve this problem

The model proposed here places the source of both group I and group II kimberlites within the asthenosphere, with group II kimberlites deriving from recycled lithospheric material This avoids having to derive spatially juxtaposed kimberlite magmas of similar age from two tectonically different source regions Details relating specific hotspot tracks to specific kimberlite pipes still need to be resolved However, the results presented here document the presence of a source region, located within the oceanic asthenosphere, capable of generating alkaline volcanism with essentially the same lithospheric signature as shown by group II kimberlites, so lending credence to models whereby kimberlite magmatism in general is related to the palaeo-positions of postulated mantle hotspots

I thank the University of Cape Town and the Foundation for Research Development for financial support, C B Smith for discussions, J J Gurney, A M Reid and S R Hart for critical comments, S R Hart for allowing me to use his unpublished data, and the British Museum for a sample of Discovery seamount

Archaean flow-top alteration zones formed initially in a low-temperature sulphate-rich environment

Donald R. Lowe & Gary R. Byerly

Department of Geology, Louisiana State University,
Baton Rouge, Louisiana 70803, USA

The 3,500–3,400 Myr Onverwacht Group in the southern part of the Barberton Greenstone Belt, South Africa, includes up to 12 km of komatiitic and tholeiitic lavas containing minor sedimentary and felsic volcanic units[1]. Komatiitic lavas showing spinifex textures, chrome spinels and high Ni and Cr contents are common throughout the sequence[2]. The rocks have been subject to polyphase Archaean deformation and low-grade metasomatism[2-4]. At several positions within the Onverwacht Group (Fig. 1), the tops of komatiitic lavas underlying chert beds are marked regionally by 1–50-m thick zones of silicification, carbonatization and K_2O enrichment (Fig. 2). Because these zones have been variously interpreted to represent the felsic tops of mafic-to-felsic volcanic cycles, weathering horizons and shear zones, their origin is germane to any interpretation of the stratigraphy, structure and evolution of the Barberton belt. Here we present evidence that they formed in

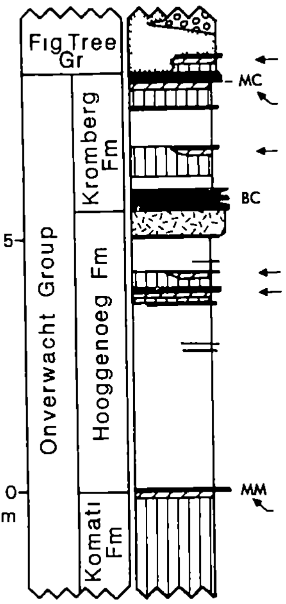

Fig 1 Generalized stratigraphic column of the Onverwacht and lower Fig Tree Groups in the southern part of the Barberton Greenstone Belt showing the distribution of komatiitic flow top alteration zones (arrows) Symbols vertical rule, komatiitic volcanic units, diagonal rule, flow-top alteration zones, unpatterned, tholeiitic units, random line segments, felsic units, black, cherts, stipple and circles, other sedimentary units, MM, Middle Marker BC, Buck Ridge Chert and MC, Msauli Chert

large part by low-temperature, near-surface alteration of komatiitic lavas during intervals of volcanic quiescence. They do not mark fault zones and cannot be used to subdivide the greenstone belt sequence into a series of fault-bounded structural slices.

The altered rock (Fig 3*a*) consists of green, silicified komatiite cut by several generations of veins but, most distinctively, by anastomosing, crudely stratiform veins of silica and carbonate[2] Komatiitic remanents have been altered to microcrystalline aggregates that can include chlorite, sericite, chrome-rich sericite, talc, carbonate and chert, but many show well-preserved silica pseudomorphs of igneous spinifex and cumulate minerals[2] Of primary igneous minerals, only chrome-rich spinels, which have compositions identical to those in less altered komatiites, have survived relatively intact Shearing effects are developed where the zones are cut by later faults, but over wide areas, primary igneous textures are finely preserved and there is no evidence of shearing, cataclasis or mineral foliation Overall, these are zones of extreme SiO_2 and K_2O enrichment and MgO and FeO depletion[5,6] (Table 1)

Crudely stratiform veins, ranging from <1 mm to >5 cm thick, compose as much as 75% of the rock (Fig 3*a*) They consist of microcrystalline quartz (chert) and ankeritic carbonate that commonly display a fine cross-vein fibrous structure (Fig 3*a*) Most fibres are straight, although not necessarily perpendicular to vein walls, but some are sigmoidal The veins contain or are separated by chunks of wall rock, and many are bounded above and below or truncated laterally by non-fibrous cavity-filling chert and druzy quartz (Fig 3*a*) These veins apparently developed by crack-sealing in response to vertical extension[7,8]

In many areas, the altered rock contains quartz nodules (Fig 3*b*) These include small quartzine (length-slow chalcedony) nodules, generally <2 mm in diameter, and large nodules, up to 5 cm in diameter, consisting of curved, radiating, plumose aggregates of length-slow pseudofibrous or flamboyant quartz

The textures of the vein-filling chert and carbonate indicate that they are pseudomorphs of earlier fibrous constituents The following features suggest that one of these constituents was gypsum (1) Within the Onverwacht Group, primary grains of coarse quartz, such as quartz phenocrysts in felsic volcanic rocks and volcaniclastic sandstones and cavity-filling druzy quartz, are preserved without alteration The microcrystalline character of the fibre-replacing quartz suggests replacement of a more poorly ordered silica type, such as chalcedony, or of a non-quartzose mineral, such as carbonate or gypsum (2) The widespread dissolution of the fibrous veins to form cavities later filled by non-fibrous silica suggests that the original vein material was highly soluble, unlike quartz and ankeritic carbonate (3) As noted by Ramsay and Huber[7], 'the length of the fibre [in extensional veins] generally has no special orientation with respect to the crystallographic directions of the crystal making up the fibre ' Virtually all fibre-replacing quartz in the alteration zones, however, shows length-slow aggregate polarization suggesting that it is a pseudomorph of a fibrous length-slow precursor, probably chalcedony Microcrystalline quartz in the adjacent wall rock is randomly oriented The associated quartz nodules also consist of length-slow fibrous and pseudofibrous quartz Whereas most chalcedony is length fast, chalcedony replacing sulphate and evaporites is characteristically length slow[9] Quartzine spherules and flamboyant quartz are also common silica replacement products of anhydrite nodules[10,11] We suggest that stratiform veins in these alteration zones were formed as satinspar or satinspar-calcite crack-sealing veins, similar to fibrous gypsum and carbonate veins widely developed at shallow levels in Phanerozoic sequences[12], and that the quartz nodules represent silicified anhydrite nodules

These distinctive alteration zones are best developed at the tops of komatiitic flow or pyroclastic sequences that are overlain directly by chert units >1 m thick Although zones of silicification and K_2O enrichment occur beneath cherts at the tops of tholeiitic and felsic sections, networks of stratiform veins and silica nodules are present only where the host rock is komatiite Primary host-rock lithology, eruptive style or eruptive setting therefore played a critical role in their formation

The upper contacts of the alteration zones are generally flat but locally show up to 6 m of erosional relief Overlying silicified sediments commonly rest with depositional contact on altered komatiite and contain komatiitic clasts and detrital chrome-rich spinels Beneath depositional contacts, the uppermost 10–50 cm

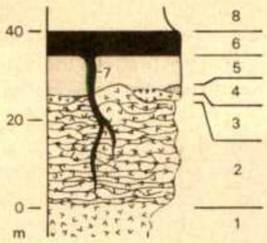

Fig. 2 Idealized sequence of lithologic units associated with alteration zones at the tops of komatiitic flow units. The areal distribution of alteration zones has been outlined previously (Fig. 3b in ref. 2). (1) serpentinized komatiite, (2) alteration zone with crudely stratiform veins, (3) breccia at top of alteration zone, (4) lenticular units of coarse-grained, poorly sorted komatiitic sandstone, (5) silicified volcaniclastic and pyroclastic deposits, (6) black and banded chert, (7) chert dikes, and (8) overlying volcanic or sedimentary units.

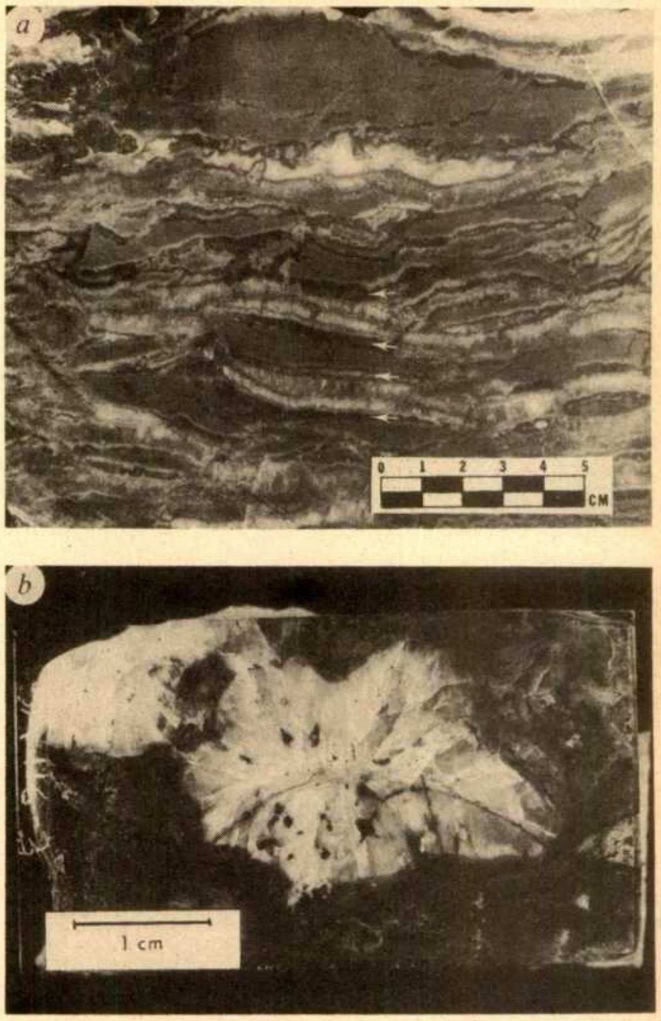

Fig. 3 *a*, Altered komatiitic flow rock showing development of crudely stratiform, fibrous veins. Medium-gray granular masses are altered komatiite remanents. Parallel layers of cavity-filling, non-fibrous chert (dark) and druzy quartz (white) adjacent (arrows) to many veins suggest at least two generations of cracking and vein development. *b*, nodules of plumose flamboyant length-slow quartz in silicified komatiite from alteration zone in the lower part of the Fig Tree Group.

of komatiite are usually brecciated (unit 3, Fig. 2). The breccias consist of angular clasts of unveined komatiite separated by dilatational chert-filled fractures that commonly contain volcaniclastic debris and carbonaceous matter similar to overlying sedimentary units. These breccias are unlike volcanic flow-top breccias and appear to have formed by *in-situ* dilatational fracturing.

Capping cherts (unit 5, Fig. 2) include silicified carbonaceous and volcaniclastic layers deposited mainly under low-energy, shallow-water conditions[13,14]. Locally, lenses of coarse-grained, poorly sorted, cross-stratified komatiitic debris (unit 4) or stromatolites in growth position rest directly on the komatiites or komatiitic breccias, reflecting more energetic shallow-water to emergent conditions[15]. The absence of chunks of stromatolite and sedimentary rock in the breccias indicates that brecciation occurred before or during deposition of the immeidately overlying sediments. Many sedimentary layers contain pseudomorphs after crystals of early diagenetic gypsum[13].

The upper parts of these sedimentary layers generally include units of black chert representing silicified carbonaceous sediments (unit 6, Fig. 2). In several areas, chert dikes (unit 7), formed by the intrastratal flowing of fluid carbonaceous oozes, extend downward from these units, through underlying sedimentary layers, and into the alteration zones. No dikes have been observed extending upward from black chert layers. These dikes truncate veins in the alteration zones, indicating that vein formation preceded diking. Both dikes and veins apparently formed before deposition of more than a few tens of metres of suprajacent sediment.

These alteration zones have been variously interpreted as altered silicic tuffs[1,16], cataclastic units marking faults[3,8], zones of relatively high-temperature hydrothermal alteration[5,6], and weathering zones[2]. Preserved igneous textures and magmatic chrome spinels indicate that the original rocks were komatiitic, not felsic volcanics[2]. Indications that the formation of these zones involved little or no shearing are: the presence of abundant, unstrained spinifex (1), the common absence of mineral foliation and cataclasis (2), their regionally stratiform non-discordant geometry over outcrop distances of up to 25 km (3), their widespread depositional contact with suprajacent sedimentary units (4) and the local presence of earlier-formed vertical veins cut but not offset by the stratiform veins (5) (Fig. 6*b* of ref. 2).

Our results suggest that these alteration zones formed through the following sequence of partly overlapping events. (1) The rapid eruption of thick sequences of komatiitic lavas in overall shallow-water settings resulted in a widespread build-up of the volcanic surfaces into the subaerial environment. (2) Post-eruption subaerial exposure of the flow tops was accompanied by erosion and the local accumulation of komatiitic alluvial sand and gravel (unit 4, Fig. 2). This may also have been a time of chemical weathering of the flow tops. (3) Regional subsidence in the absence of volcanism led eventually to submergence. Passage of the flow tops through marginal evaporitic environments was associated with planation, formation of anhydrite nodules, brecciation, and local growth of stromatolites. (4) Shallow-water deposition of volcaniclastic and carbonaceous sediments resulted in infiltration of the breccias by loose debris and the accumulation of sediment caps on the komatitic flows. (5) Silicification of fine-grained volcaniclastic units began almost concurrently with deposition[13,17], forming nearly impermeable chert caps above the alteration zones. Silicification of the upper parts of the lavas may also have begun at this time. Fluids moving through the volcanic rocks were trapped beneath these seals resulting in hydraulic overpressuring and formation of crack-seal veins. These were low-temperature fluids, probably less than 60 °C, as suggested by the precipitation of gypsum[18]. They may have been dense sulphate-rich brines originating in marginal evaporitic environments. (6) The formation of chert dikes reflects fracturing of the chert caps above the alteration zones and may mark the release of hydraulic overpressures and the end of vein formation. Later changes in pore-water chemistry, perhaps related to burial or the upward movement of deeper-level, higher-temperature fluids, resulted in gypsum replacement and later stages of silicification, carbonatization and K_2O enrichment. Where the chert caps remained intact, the formation of additional crack-seal veins may have accompanied these metasomatic events.

The results of this study indicate that these distinctive Archaean alteration zones formed initially through a complex sequence of surface and near-surface low-temperature processes. Later metasomatism and metamorphism also played a major role in their final character. Studies of this and other flow-top alteration zones may provide important clues to Archaean water and atmospheric chemistry, surface and subsurface hydrologic systems, and the relationships among volcanism, subsidence and sedimentation in greenstone belts.

Body size, ecological dominance and Cope's rule

James H. Brown & Brian A. Maurer*

Department of Ecology and Evolutionary Biology,
University of Arizona, Tucson, Arizona 85721, USA

We present data and analyses demonstrating that large species utilize a disproportionately large share of the resources within local ecosystems. Even though small species tend to have higher local population densities, these are not sufficient to compensate for their lower rates of energy use per individual. The relationship is very general; holding for example for birds, mammals, fish and plants. We suggest that several ecological advantages enable larger species and larger individuals within species to monopolize resources, and that the resulting selection pressures are responsible for the evolutionary trend towards increasing body size seen in many phyletic lineages. Our results contradict important studies[1–4] that have concluded that species of small body size use at least as large a proportion of the resources within ecosystems as their larger relatives.

A goal of community ecology is to understand the patterns and processes that determine the numbers and variety of coexisting species. Are there general rules that characterize the contributions of the different species to the structure and dynamics of ecosystems? One measure of the ecological importance of species is their relative utilization of energy and transfer of materials[5,6]. Within groups of taxonomically-related, ecologically similar organisms, two variables (individual body size and population density) are of primary importance in determining how energy and other limiting resources are allocated. Large individuals demand more from environmental resource pools than small ones, but also tend to occur at lower population densities. The question, then, is to what extent the greater abundance of small species compensates for their lower resource requirements per individual.

Although direct measurements of energy flow per unit area are probably not available for all species in any community, these rates can be estimated quite accurately from data on population density (D), individual body mass (M) in animals and photosynthetic cover (C) in plants. In animals the average daily energy use of a free-living individual (U) scales allometrically as approximately $M^{0.67}$ (refs 2, 7–10), so total energy use per species (E) is given as $E = DU = DM^{0.67}$. In plants, variation in photosynthetic rate per unit leaf surface among species is insignificant compared to the total leaf surface[11,12], so the energy use of each species is directly proportional to its vegetative cover (C).

We analysed data on D and M for local groups of birds, mammals and fish, and on C for communities of plants to determine how rates of energy use per species (E) varies with body size. Using the results of 39 censuses of breeding land birds and data on species body mass[13], we tried three different methods[14] to fit a linear relationship for log D with log M (Table 1). Depending on the method, only 3 to 10 of the 39 slopes were ≤ -0.67. Pooling the data gave a slope of approximately -0.30, not greatly different from the value of -0.19 reported by Peters[2]. If D scales as $M^{-0.30}$ and U scales as $M^{0.67}$, then the rate of energy intake per species ($E = DU$) increases with body mass, scaling as $\sim M^{0.37}$. Because the three methods of estimating slopes give comparable results, in the following analyses we present only the results of the regression method applied to log-transformed data.

For the nine species of granivorous rodents (mammals) in a Chihuahuan Desert ecosystem[15], regression of log D on log M gave a significant positive relationship ($r = 0.56$, slope $[b] = 1.17$, $n = 9$, $P = 0.05$). Consequently, in these mammals the rate of energy flow per species ($E = DU$) scales positively with body mass as $\sim M^{1.17} \times M^{0.67} = M^{1.84}$.

We analysed three independent data sets[16–18] on population densities and body masses of marine fish (Table 2). The slopes of regressions of log D on log M averaged near zero, and only one was more negative than -0.1. Thus, if D scales as $\sim M^{0.0}$ and U scales as $M^{0.67}$, then the average rate of energy use per species ($E = DU$) must vary as $\sim M^{0.67}$.

We obtained complete census data for perennial plants in five different habitats in two desert regions[19,20]. Total cover (C) of each species was used to estimate its contribution to energy flow, and cover divided by population density (D) was taken as the effective size of an individual plant. When we regressed log C against log (C/D), all the slopes were positive, with values ranging from 0.53 to 1.59 and averaging ~ 1.0 (Table 3). Although the usefulness of estimating individual mass in perennial plants containing nonliving woody tissue is questionable, M should vary with individual surface area as $\sim (C/D)^{1.5}$ and rate of energy use per species (E) should scale as $> M^{1.0}$.

Our analyses show that in four different taxonomic groups (birds, mammals, fish and plants) species comprising large individuals account for most of the energy flow and resource use within local ecosystems. These results contradict those of two influential recent studies. Damuth[1] claimed that population densities of mammals scale as $M^{-0.75}$, so that rates of energy use per species are essentially independent of body size (E scales as $\sim M^{0.0}$). Peters[2–4] compiled data which suggest that population density (D) often scales as $M^{-1.0}$ so that energy use per

---

species should scale negatively with body mass (as $M^{-0.33}$). The results of Damuth and Peters can probably be attributed to a sampling bias inherent in their data collection procedures. Their analyses are based on published values of population densities for species from different, scattered localities. These data probably neglect the numerous rare species of small body size that occur within local ecosystems, because ecologists tend to study conspicuous and abundant species. We have been careful to avoid this and other possible biases by using only complete censuses of local biotas.

We have calculated the slopes of allometric equations to reveal differences between our results and those of Damuth and Peters. However, the low correlation coefficients of our regressions suggest that no allometric equation adequately characterizes the

Table 3 Regression analyses of log cover on log (cover/population density) for perennial plants in five different habitats in two desert regions of southwestern North America

relationship between population density and body size. Our qualitative result that on average small species use proportionally less energy than large ones can be corroborated using a robust nonparametric technique. We divide the species in a census into those above and below the median body mass for species in that census. Then if population energy use (E) is on average greater for larger than for smaller species, then $\bar{E}_s < \bar{E}_l$, where $\bar{E}$ represents mean energy use of the smaller (s) and larger (l) species. For animals in which individual energy use scales as $M^{0.67}$, we can substitute $\bar{D}\bar{M}^{0.67}$ for $\bar{E}$, so $\bar{D}_s\bar{M}_s^{0.67} < \bar{D}_l\bar{M}_l^{0.67}$. Because the probability that any one census obeys this relationship by chance is 0.5, whenever we have a sufficient number of censuses we can use a binomial test to evaluate the hypothesis that the collection of censuses exhibits the expected pattern. For the bird censuses in Table 1, 35 out of 39 showed the predicted relationship (one-tailed test, $p < 0.0001$).

We have shown that on a per species basis, within trophic levels and taxonomic groups, organisms of large individual size account for most of the energy flow through local ecosystems. This has important ecological and evolutionary implications. There are several ecological advantages of large body size. Large species are usually dominant in interspecific aggression[21], which may result in exclusion of small species from preferred resources; they tend to have more efficient homeostatic mechanisms and greater mobility[2,8,10], so they are able to tolerate a wider range of environmental conditions and to seek out more favourable locations. An increase in size enables an individual to spend less energy per unit biomass on maintenance and to become more efficient at extracting usable energy from low-quality foods[2,22]. Consequently, the same amount of available energy can support a greater biomass of a large species than of a small one. Finally, size may be important in avoiding predators[23]. Our data suggest that these advantages enable large species to dominate the resource allocation in ecosystems, leaving smaller species to divide up the remainder.

The ecological consequences of body size provide a mechanistic explanation for the evolutionary cycle known as Cope's rule[23,24]. Phylogenetic lineages usually begin with relatively small organisms that give rise to larger forms. Ultimately giant forms are produced, but these frequently become extinct, creating new opportunities for another lineage as it in turn evolves organisms of larger size. Presumably the ecological advantage of monopolizing resources provides the selective pressure that promotes evolution of greater size. Individuals of large size are favoured by intraspecific natural selection, because they can dominate resource use and consequently leave more offspring than their smaller relatives. However, this increase in body size is accompanied by a higher probability of extinction, which may be attributed to lower population density, smaller population size, slower population growth and perhaps other factors[23,24]. Thus Cope's rule is the result of two opposing evolutionary processes, one operating at the level of individuals within populations, and the other at the level of species within ecosystems[25].

Mach bands are phase dependent

M. Concetta Morrone, John Ross, David C. Burr & Robyn Owens*

Department of Psychology and * Department of Computer Science, University of Western Australia, Nedlands, Western Australia 6009, Australia

The prevailing explanation of Mach bands, the paradoxical bands of light and dark seen where luminance gradients meet plateaux, is that they are due to lateral inhibition in the visual system[1–4]. This explanation equates Mach bands with distortions in a processed luminance distribution due to selective attenuation of low frequency components. But square waveforms exhibit no Mach bands[2,5,6], although they should also be distorted after processing. Measurements of the contrast required to see Mach bands in trapezoidal waveforms and manipulations of their spectra lead us to conclude that phase relationships between Fourier components are important to the structure we perceive. A model based on the odd and even symmetry of visual receptive fields explains our results.

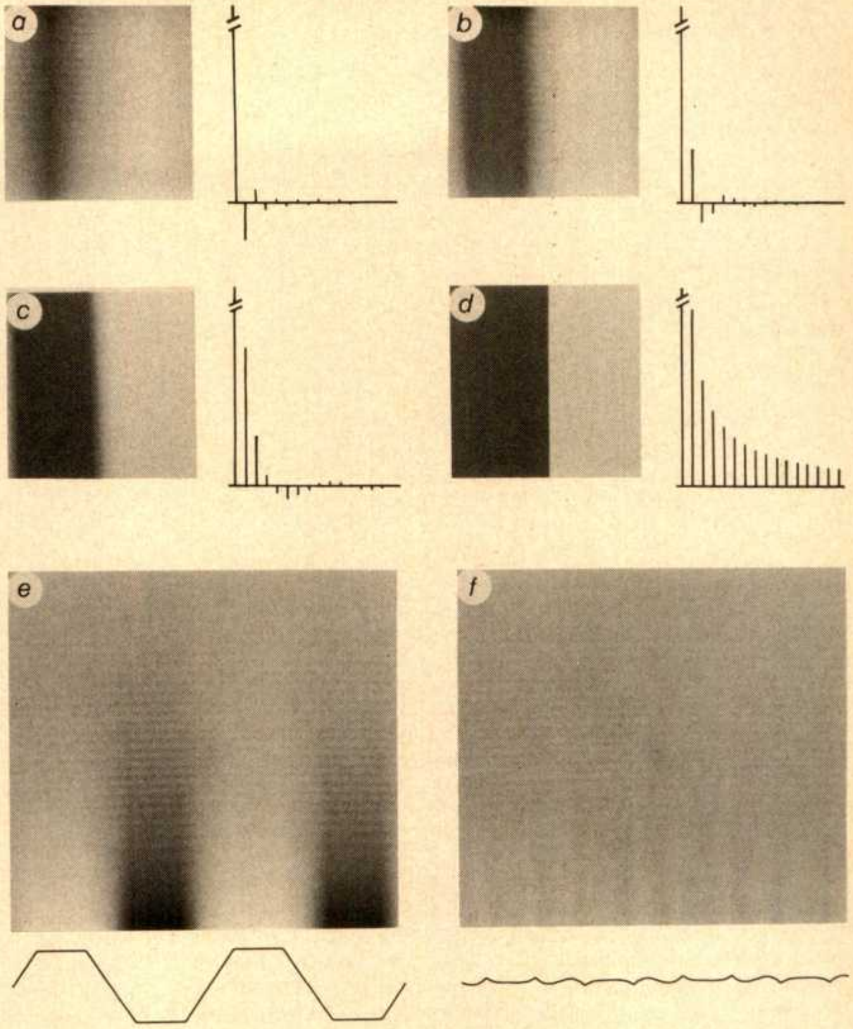

Fig. 1 *a–d*, Examples of four types of trapezoids. The shape of the waveform is determined by the parameter t (the ratio of the ramp width to the period), which is 0.5 in *a* (triangular wave), 0.25 in *b*, 0.125 in *c*, and 0 in *d* (square wave). Mach bands are clearly visible in all except the square wave. The Fourier expansions of the patterns are given by

$$F(x)=\sum_{k=0,\infty}[(4A/t\pi^2)\cdot(\sin(\pi t(2k+1))/(2k+1)^2)]\cdot\sin(2\pi(2k+1)x/T), \qquad (1)$$

where A is the amplitude and T is the period. The spectra are depicted schematically adjacent to each waveform (the first harmonic terms are not to scale). Only the odd terms are non-zero, and they fall into alternatively positively and negatively weighted blocks whose size varies inversely with t. *e, f*, At left a trapezoid waveform ($t=0.25$), decreasing in contrast exponentially upwards. At right the residual waveform, from which the first block of positively weighted harmonics (the first and the third) has been removed, also decreasing in contrast exponentially upwards. For various distances (spatial frequencies), note the point at which the Mach bands disappear from the trapezoid, and also the point at which the residual waveform falls below detection threshold. The two thresholds should be similar. By fixating some distance below the two panels that Mach bands disappear in the periphery as contrast decreases well before the residual ceases to be visible.

Mach originally[7] used rotating discs and drums to study the bright and dark bands that appear where ramps of luminance meet plateaux as, for example, at the borders of the penumbra of a shadow. He later devised optical methods to cast shadows[8]. For the studies reported here we used gratings formed by computer on an oscilloscope which were variable in luminance profile and contrast. Fig. 1 shows four trapezoids, including the two extreme cases of a square wave ($t=0$) and the triangular wave ($t=0.5$), where t is the ratio of the width of each ramp to the period. Classical Mach bands are seen on the trapezoids (Fig. 1*b*, 1*c*); bright bands are visible at the top of each ramp and dark bands at the bottom. Note also that the ramps do not appear to have a uniform brightness gradient and the plateaux do not appear uniformly dark and light. The triangular wave also exhibits sharp bands at the peaks and troughs of the waveform, but the square wave does not.

The Fourier transforms of the trapezoid waveforms (calculated from the point where the waveform crosses zero) are also shown in Fig. 1. The components are arranged in blocks alternatively positively and negatively weighted (that is, differing in phase by 180°). The number of components in each block varies inversely with t (see formula in the legend), being one for the triangular wave, and infinite for the square wave. The observations that Mach bands are not seen on square waves[2,6], which have no out-of-phase components, or on trapezoids with very steep ramps[5], where the out-of-phase components are all of high spatial frequency, led us to suspect that phase may hold the key to Mach bands.

We isolated residual waveforms from trapezoids by removing the first block of positive harmonics (see Fig. 1*f*) and measured the contrast necessary to see them as a function of spatial frequency (inverse of their period, T in equation (1), Fig. 1, legend). The results are shown by the filled circles in Fig. 2. We then measured the minimum contrast at which Mach bands could be seen in the original trapezoidal waveforms (open triangles in Fig. 2). The two curves follow one another closely as spatial frequency is varied. Interestingly, observers spontaneously remarked that the two tasks, setting thresholds for seeing Mach bands and for detecting residual waveforms, seemed to make common demands on them, as if the two tasks were almost identical. Readers can confirm some of the results for themselves by observing the contrast at which the Mach bands of Fig. 1*e* and the pattern of Fig. 1*f* disappear at various viewing distances.

This result suggests that Mach bands are visible only when the out-of-phase Fourier components (together with all higher harmonics) reach their independent threshold. To test this more directly, we attenuated the higher frequency components by applying a low-pass gaussian filter to various trapezoidal waveforms and decreased the space constant of the gaussian filter until the Mach bands disappeared. We then applied the same filter to the residual waveforms. For all the trapezoids we investigated, the low-pass filter which removed the Mach bands attenuated the appropriate residual waveform to a contrast just below its detection threshold.

It is known that phase discrimination deteriorates in the periphery[9,10]. We measured the contrast required to see Mach bands in various trapezoids and the contrast required to see their residuals as a function of retinal eccentricity. As eccentricity increased the contrast required to see Mach bands increased

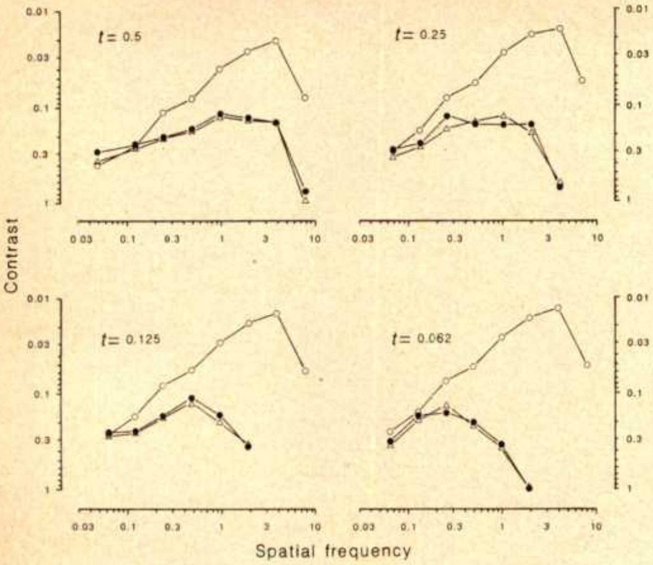

Fig. 2 Contrast required to see Mach bands as a function of spatial frequency (c per deg) is shown by open triangles, for four different t values. Contrast required to see the residual waveform (first block of positive components removed) is shown by the filled circles. The curves follow one another closely. Open circles show contrast required to see the fundamental of the trapezoid, for comparison. All contrasts are expressed as those of trapezoids from which the waveforms derive.

much more rapidly than that required to see the residual. Indeed, Mach bands could not be seen at all at eccentricities greater than three degress (as previously observed by Mach[8]), whereas the residual was still clearly visible. Phase sensitivity is indeed poor in the periphery; when viewed peripherally, trapezoids become unstable and alternate in appearance between square and triangular waves.

As a final confirmation of the importance of phase, we created synthetic waveforms by inverting the sign of all negatively weighted components of the triangular wave ($t = 0.5$) and a trapezoid ($t = 0.25$), to make 'all positive' waveforms, having the same amplitude spectra as the parent trapezoids (Fig. 3). As can be seen, the luminance profiles are now smooth. There are no Mach bands in either case, but sharp edges are apparent, similar to those of a square wave.

The effects of phase on the appearance of distributions of luminance are more radical when there is variation in two dimensions. The distribution of luminance in Fig. 3*c* is pyramidal. In both horizontal and vertical cross-section, the luminance profile is triangular. The Mach bands of one dimensional triangular waveforms reappear in two dimensions as star-like patterns where the two dimensional pattern forms points of high and low luminance. Adjacent is the same pattern with all phases set positive. The structure is now like that of a checkerboard, with white and black squares clearly separated by sharp vertical and horizontal borders.

The results of this study suggest that Mach bands are different from edges, but that both depend on phase relationships. When all negative harmonics (180° out-of-phase) are rendered invisible (by lowering their contrast, increasing their spatial frequency, or smooth digital filtering), Mach bands disappear. When patterns are displayed peripherally (where the visual system is poor at resolving phase[9,10]) the bands also disappear. Finally, if all negative harmonics of a trapezoid are shifted in phase by 180°, Mach bands disappear, but an edge is seen where there was none before.

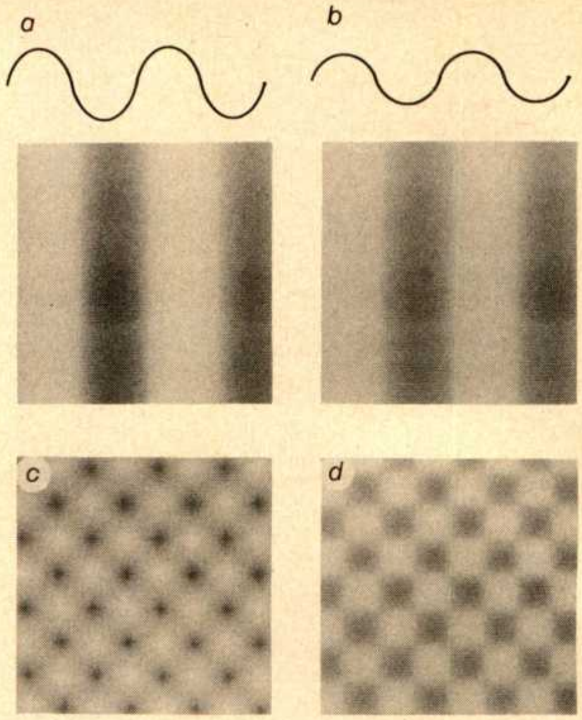

Fig. 3 *a, b*, Synthetic waveforms constructed by inverting the sign of all negatively weighted components of trapezoids of t value 0.5 (*a*) and 0.25 (*b*). The waveforms have no discontinuities, yet we perceive sharp edges, with no Mach bands; *c*, two dimensional pattern formed by multiplying a horizontal by a vertical triangular wave, shows white and black star patterns whch are two-dimensional analogues of Mach bands; *d*, two dimensional pattern derived from *c* by inverting the phase of all negatively weighted harmonics. The star patterns reflecting two-dimensional Mach bands are no longer visible. Instead, a checkerboard-like pattern is seen, with sharp borders between the black and white squares.

As mentioned earlier, all harmonics of a square wave are in zero phase at the point where the waveform crosses zero in a positive direction and 180° where it crosses zero in a negative direction. This is also true for 'all positive' trapezoids in which all out-of-phase components have been shifted in phase by 180°. Elsewhere, the phases of the harmonics advance at different rates, so no other points have strong congruence of phase. Trapezoidal waveforms other than the square wave have blocks of negatively weighted harmonics which break the congruence of phase at the zero-cross point. However, the periodic halt of the phase advance of the harmonics causes the phases to pile up around ±90° at the points where the ramps meet plateaux. A phase grouping around 90° is typical of that produced by delta functions and bars and may be the signal that produces Mach bands.

Why should the visual system react so strongly to phase relationships? A two dimensional basis is required to extract phase information. The even and odd symmetry of receptive fields of the visual cortex[11] could form such a basis. The receptive fields vary in size, also allowing for coding of an image at different spatial scales[12-15]. The potential ability of such a system to signal edges (odd-symmetric) and lines (even symmetric) has been noted by many investigators[15-18]. We suggest that an efficient means for the visual system to locate bars and edges would be to consider the sum of the squared output of even and odd symmetric filters, which always peaks at points of phase congruence. After the peak had been located the response of the odd and even fields at that point would determine if it were due to an edge or a bar, and give the sign and contrast of the edge or bar. The clustering of phase around 90°, which occurs with trapezoids, should also signal a bar or stripe.

Phase is thought to be encoded by even and odd symmetric detectors in the human visual system[19]. It has further been shown that the sensitivity of the odd, but not the even, symmetric mechanism is reduced in peripheral vision[20]. This would account for the disappearance of Mach bands in the periphery, at contrasts well above those required for the independent detection of out-of-phase harmonics.

Although the generally accepted explanation of Mach bands is that they are due to lateral inhibition, several investigators have noted the problem this presents for square waves and sharp edges[2,5,6,16] and have considered other possibilities. Tolhurst observed that even symmetric receptive fields (which he termed bar detectors) may signal Mach bands[16]. He also speculated that for the square wave the response of odd symmetric fields (edge detectors) may inhibit that of the even symmetric fields (bar detectors), so no stripes are seen (see also ref. 6). Watt and Morgan's[21] general theory of spatial vision also predicts bar signals at the border of a ramp, provided that they are far enough apart. Both these ideas have some similarity to ours, but our results (and simulations to be reported in a fuller paper) suggest that inhibition between edge detectors and bar detectors is unnecessary.

Finally, we note that trapezoids, like square waves and synthetic 'all positive' trapezoids, show zero-crossings at all scales at the mean luminance point. If edges were encoded by alignments of zero-crossings, as has been assumed[22-24], all should have edges at that point. But trapezoids do not. A model seeking phase congruence as the signature of bars and edges, built on adequate basis functions, can without ambiguity, locate edges and bars where we see them.

Hysteresis in the perception of motion direction as evidence for neural cooperativity

Douglas Williams, Gregory Phillips & Robert Sekuler

Departments of Neurobiology/Physiology and Psychology,
Northwestern University, Evanston, Illinois 60201, USA

When elements of a parallel network, such as the human brain, are extensively interconnected, the network can exhibit 'cooperative behaviour'. Such behaviour, which is characterized by order–disorder transitions, multi-stable states, and a form of memory called 'hysteresis', has been observed in human stereopsis[1,2] and has motivated models of stereopsis that incorporate cooperative networks[3–6]. More recently, cooperative phenomena have also been observed in human visual motion perception[7]. This report strongly supports a cooperative interpretation of motion perception by demonstrating hysteresis in the perception of motion direction. The results agree quantitatively with a mathematical model incorporating nonlinear excitatory and inhibitory interactions among direction-selective elements.

Our stimuli were dynamic random dot cinematograms comprising 512 computer-generated dots. Each dot took an independent, two-dimensional random walk of constant step size (0.9°). The direction in which any dot moved was independent of its own previous displacements and also of the displacements of the other dots[8].

The direction of motion for each dot was chosen from either (1) one of two uniform distributions, or (2) a mixture of these two distributions. When all dots drew their movements from a uniform distribution extending over 360°, only the 'local random motion' of individual dots was evident. This resembled a detuned television set. However, when all dots drew their movements from a uniform distribution of 180° or less, the dots appeared to flow *en masse* in the direction of the distribution mean—although individual perturbations were still evident. This resembled snowflakes that, although individually perturbed by wind currents, seem to drift in one direction. In all experiments the mean of the signal distribution was upward.

For convenience, we refer to the 180° and 360° distributions as the signal and noise distributions, respectively. When dots drew their movements from a combination of these distributions, each dot's displacement came randomly from either distribution. The resulting perception depended upon the relative proportions of noise and signal.

Two types of trials were run in random order. In one, the direction of motion for each dot was chosen initially from the signal distribution, producing a perception of upward flow. After a random interval lasting up to 12 seconds, the proportion of dots drawing directions from the signal distribution was decreased and the proportion of dots drawing directions from the noise distribution was increased. The observer responded when the cinematogram changed in appearance from upward flow to local random motion. After this response, the proportion of signal continued to decrease for a random interval (up to 6 seconds). The process was then reversed, with the proportion of signal increasing until the subject responded that the upward flow had reappeared. This terminated the trial. For the second trial type, the stimulus sequence was reversed. We started with an initial percept of local random motion, and measured the points of transition to a perception of upward flow and back again to local random motion. These two different trial structures—signal-first and noise-first—were designed to produce different histories of directional exposure and thus reveal any perceptual effects dependent upon the history of stimulation. For both trial types, the signal to noise ratio changed slowly, with the proportion of dots sampling from each distribution changing by just two dots per frame. At the frame rate of our display, 10 Hz, it took a minimum of 25 seconds for the display to shift from complete dependence on one distribution to complete dependence on the other.

Observers used one eye to watch the centre of a circular display 16° in diameter. The dots were presented at twice threshold luminance against a dim background. Over the course of 5 sessions we made 100 measurements of the signal proportion at the two perceptual transitions for each of our three naive observers.

We repeated this experiment with two narrower ranges of signal distribution: 90° and 1°. Each of the three signal distributions generated a different history of exposure. We expected that, as the distribution narrowed, the signal would become

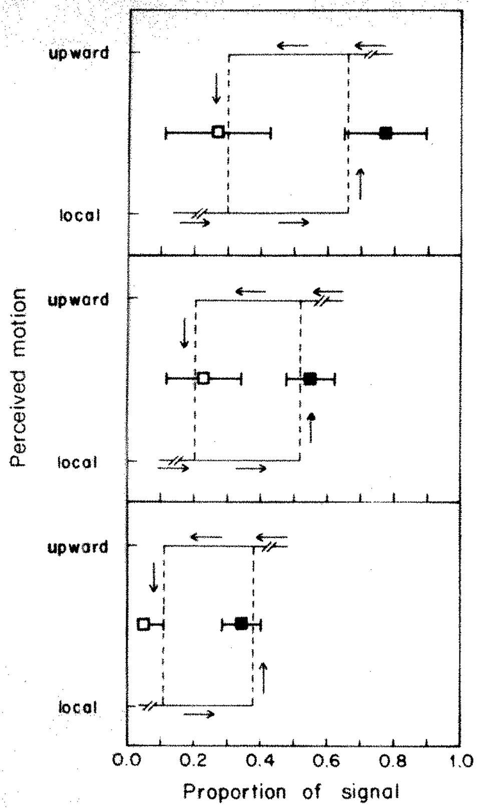

Fig. 1 Perceptual transitions measured under two different histories of stimulus exposure (indicated by arrows) for three signal distributions. The results, for observer J.F., were obtained for signal distributions whose ranges were: top, 180°; middle, 90°; bottom, 1°. Data points show proportion of 'signal' dots required for perceptual transition from local random motion to upward flow (■) and for perceptual transition from upward flow to local random motion (□). Error bars indicate one standard deviation (100 measurements). In each panel the separation between transition points measured with the different exposure histories is an index of hysteresis. The dashed lines mark the transition points calculated from a model incorporating cooperative interactions among direction-selective motion elements.

more effective in stimulating directionally selective visual elements that are tuned to upward motion. As a consequence, the occurrence of a transition between perceived states would require fewer signal dots.

The results for one observer are shown in Fig. 1; similar results were obtained for the other observers. Each panel shows data for a different range of signal. Note that the transitions differ for the three signal ranges. More importantly, the transition from noise-to-upward flow requires a larger number of dots sampled from the signal distribution than does the transition from upward flow-to-noise. For all three signal distributions, the two types of transition occur at significantly different ratios of signal to noise ($P<0.005$).

Before attributing our results solely to neural hysteresis, a number of alternative explanations were considered and rejected. For example the motion after-effect, or waterfall illusion, did not produce our results as this after-effect would probably have facilitated, rather than retarded, the transition from upward motion to noise. Also, the results were largely unchanged by the use of a fixation point, suggesting that eye movements probably played little or no role. Finally, reaction time could be dismissed given the slow time course for changing the signal proportion.

Before developing a simple network that could describe our results, we needed a fuller account of how spatial parameters might affect hysteresis. Using a 180° signal distribution, we made measurements (1) with a four-fold decrease in the spatial density of the cinematogram's dots, (2) with a four-fold decrease in the area of the display and (3) with the display shifted horizontally into the periphery of the visual field so that the nearest dot was 4° from fixation. None of these variations produced results that differed greatly from our original measurements. Of course, extreme changes in these display parameters would undoubtedly alter the hysteresis characteristics. However, because of these data and demonstrations suggesting that spatial variables have little effect on the dot interactions responsible for motion in cinematograms[8,9], we chose not to treat space explicitly in developing a model network to describe our results.

The model comprises a set of direction-selective mechanisms covering all 360° of motion direction, with each direction-selective mechanism having a gaussian profile for directional sensitivity. Based on previous results from our laboratory, the half-amplitude half-bandwidth of each mechanism's gaussian sensitivity profile was set to 30° (ref. 10). The model, whose mathematical formulation is a modification of the cooperative neural network previously proposed[4], assumes non-linear excitatory interactions among mechanisms sensitive to similar directions of motion and non-linear inhibition among mechanisms sensitive to different directions. The dynamic response of this cooperative system is represented by a pair of coupled differential equations. For the excitatory activity, E_i, in direction channel i:

$$\mathrm{d}E_i/\mathrm{d}t = -E_i + (1-E_i)S\left(P_i + \sum_j a_j E_j - \sum_j b_j I_j\right)$$

where S is a nonlinear function of sigmoidal shape, P_i is the external input to channel i, and a_j, b_j are the excitatory and inhibitory weights, respectively, of channel j with respect to channel i. A similar equation gives the inhibitory activity I_i, in channel i. In general terms, such interactions promote the formation of stable 'coalitions' among similarly tuned elements within the network[11]. These neural coalitions can in turn produce various cooperative properties, including hysteresis.

The parameters of the model were constrained so that the model behaved in what is defined[4] as the active transient mode. In this mode the system shows hysteresis, switching between different states of activity. In the model simulation the perception of local random motion is represented by a steady state of uniform activity across all mechanisms. Global upward flow is represented by a steady state in which the activity is localized about the mechanism selective for upward movement. A transition point is defined by the proportion of signal at which the network switches between these two states of activity. The results from the model are shown in Fig. 1. Dashed lines mark the transition points calculated from the model using a single parameter set. It can be seen that the model captures both the leftward shift and narrowing of the hysteresis profile with decreasing signal range. The model's behaviour here is readily explained. With decreasing signal range more activity is concentrated in fewer motion-selective elements arrayed about the upward direction. Consequently, a smaller proportion of signal dots suffices to indicate upward movement. In addition, fewer active elements reduces the opportunity for cooperative interactions in the network, which translates into a narrowing of the hysteresis profile[2].

If we accept the idea that the perception of motion direction depends upon a cooperative neural network, there may be circumstances outside the laboratory in which this network's cooperativity might be especially useful. Observers must extract a mean direction vector from a scene containing a great many different local vectors in many naturally-occurring situations. For example, we can judge the average direction in which the ocean's surf moves despite the fact that individual waves move along somewhat different paths; or we can judge the average direction in which the wind blows the leaves of a tree despite the random variation of that movement from one leaf to the next (or for any one leaf over time). Faced with such multivectorial stimuli, a cooperative network like the one embodied in our model would enhance the signal-to-noise ratio and thereby facilitate the perception of the mean direction of motion.

Glycine and γ-aminobutyric acid (GABA) are inhibitory transmitters of major importance[1,2]. Whereas neurones using GABA as the transmitter can be visualized by immunocytochemical methods for glutamate decarboxylase (GAD)[3,4] or GABA[5-8], no comparable techniques have been available for the selective visualization of glycinergic neurones. We have now produced polyclonal antibodies which specifically recognize glycine in glutaraldehyde-fixed tissue. We used these antibodies to investigate the distribution of glycine in the simple central nervous system (CNS) of the *Xenopus* embryo, which contains an anatomically and physiologically defined class of reciprocal inhibitory interneurones, the commissural interneurones[9-11]. These interneurones have an important role in the generation of the swimming motor pattern and are thought to be glycinergic[11-13]. The glycine antibodies specifically stain these interneurones, revealing their distribution and number in the embryo CNS. This is the first demonstration of the selective localization of glycine-like immunoreactivity in a putative glycinergic class of neurone that has been characterized physiologically, pharmacologically and anatomically.

Evidence for glycine as a transmitter in the vertebrate spinal cord has been based on four types of information: the actions of exogenous glycine[14,15], specific blockade by the antagonist strychnine[14,15], the depletion of glycine following ischaemic degeneration of spinal interneurones[16,17] and the demonstration of neuronal uptake of ^{3}H-glycine[18-21]. However, antagonism of an inhibitory postsynaptic potential (i.p.s.p.) by strychnine is not unequivocal evidence that glycine is the endogenous transmitter: the hyperpolarizing actions of β-alanine and taurine (amino acids closely related to glycine; Fig. 1) are also blocked by strychnine[2]. In the absence of further evidence β-alanine and taurine must therefore also be considered as candidate transmitters. We decided to raise antibodies which could selectively recognize glycine in glutaraldehyde-fixed nervous tissue and could be used to localize glycine in neurones. Modifications of our methods[5,6] have been used previously by Pourcho and Goebel[22] to produce and test a glycine antiserum which marks cells in the cat retina and brain stem.

Glycine was coupled to carrier proteins by means of glutaraldehyde as described previously[5]. As suggested by Seguela *et al.*[7], the carrier protein was changed, here for each immunization, to avoid boosting the immune response to the carrier protein and any particular configurations of the glycine-glutaraldehyde complex that might depend on the protein (Fig. 1 legend). Unwanted antibodies recognizing glutaraldehyde-treated amino acids and proteins were removed by immunosorbent chromatography on a sequence of columns (Fig. 1 legend). The purified antiserum was initially tested for crossreactivity with a series of compounds conjugated by glutaraldehyde to a total macromolecular extract from rat brain and spotted on cellulose ester filters[6]. The compounds were GABA, taurine, phosphoethanolamine, β-alanine, L-α-alanine, valine, leucine, proline, serine, threonine, tryptophan, tyrosine, histidine, lysine, arginine, ornithine, aspartate, *N*-acetylaspartate, glutamate, asparagine, glutamine, methionine, cysteine, reduced glutathione, α-aspartylglycine, carnosine, homocarnosine, cadaverine, putrescine, spermine and spermidine. While the glycine conjugate was intensely stained, none of the other conjugates were stained appreciably darker than 'null' conjugates (macromolecular extract treated with glutaraldehyde in the absence of amino acid). The staining was abolished by solid-phase absorption with glycine fixed to ovalbumin or to lysine by glutaraldehyde (Fig. 1 legend).

To check the specificity of these antibodies in the *Xenopus* embryo we made two different sets of conjugates, one of macromolecules from whole embryos and one of macromolecules from the CNS of adult *Xenopus*. To ensure identical conditions for testing and immunocytochemistry, the test filters with these conjugates were processed in the same vessels as the tissue preparations. The tissue consisted of the CNS of *Xenopus* embryos stage 29/30 to 37/38 (ref. 23) raised by induced breeding in Bristol, fixed in glutaraldehyde and shipped to Oslo for dissection and processing[6] of the CNS.

The results with *Xenopus* conjugates (Fig. 1*a*) were similar to those with rat brain conjugates. A glycine-glutaraldehyde complex, added to the diluted antiserum (at a final concentration of 100 or 300 μM with respect to glycine) completely abolished staining of the glycine spots and of the tissue (Fig. 1*e*, *f*). Complexes of β-alanine (Fig. 1*c*, *d*), L-α-alanine, GABA or reduced glutathione (all at 300 μM), or a mixture of individual glutaraldehyde complexes of taurine, aspartate, glutamate, glutamine and serine (all at 300 μM) produced no reduction in the staining of glycine test spots (the converse is seen in ref. 32) or tissue.

The *Xenopus* embryo spinal cord appears on the basis of retrograde horseradish peroxidase (HRP) filling to contain eight anatomically distinct neurone classes[9]. One of these, the commissural interneurones, is defined by the following anatomical features[9]: (1) a unipolar soma in a middle to dorsal position in the cord, (2) a single ventral process bearing dendrites that extend laterally into the marginal zone (lateral tract) and (3) an axon crossing ventrally to ascend and sometimes also descend contralaterally (Fig. 3*a*). These neurones have been shown by intracellular recording and HRP injection to be active during fictive swimming[10] and to produce mid-cycle i.p.s.ps in contralateral motoneurones[11]. The mid-cycle i.p.s.ps in motoneurones and the response to exogenous glycine (100 μM) have a reversal level near the resting potential, depend on an increase in chloride permeability and are unaffected by 10 μM bicuculline, but are blocked by 1 μM strychnine[11,13,24]. The commissural interneurones may therefore be glycinergic.

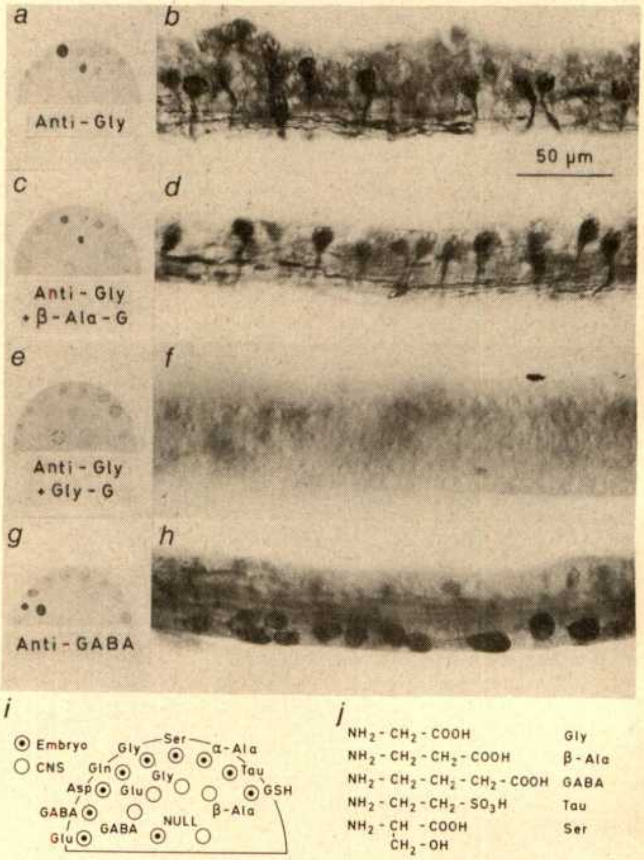

Fig. 1 The purified glycine antiserum (31, 1:90) gives selective staining of test spots of glycine fixed by glutaraldehyde to macromolecules from *Xenopus* embryos (pigmented) (⊙) or adult CNS (○) (*a*, *i*), and selective staining of a characteristic class of neurones, the commissural interneurones, in whole-mounts of the spinal cord of *Xenopus* embryos (lateral view) (*b*). The specific staining is abolished by glutaraldehyde complexes of glycine (Gly-G) (*e*, *f*), but not by complexes of the closely related β-alanine (300 μM added to the diluted serum) (*c*, *d*). In comparison, a purified GABA antiserum (26, 1:200)[6] stains only the GABA spots (*g*) and different cells[25] (*h*) from those stained by serum 31. The structures of the amino acids most closely related to glycine are shown (*j*); standard symbols are used for amino acids; GSH, γ-glutamylcysteinylglycine (glutathione).

Methods. The serum was raised by immunizing a rabbit (intracutaneously on the back at 6-week intervals with 125 μg protein in Freund's complete adjuvant; Gibco) with glutaraldehyde conjugates (0.3–1 μmol of glycine bound per mg protein) of a sequence of carrier proteins: keyhole limpet haemocyanin (Calbiochem), casein (Sigma), human haemoglobin (Sigma), lysozyme (Worthington), *Limulus polyphemus* haemocyanin (Sigma), horse skeletal muscle myoglobin (Sigma) and bovine thyroglobulin (Sigma). Portions (50 μl) of the crude serum were applied to a set of three microcolumns (i.d. 0.3 cm) connected in series and containing protein (6 mg per ml gel) coupled to agarose particles (Sepharose 4B, Pharmacia[27]) and reacted with glutaraldehyde (Taab, EM-grade, 75 μmol per ml gel) in the presence or absence of amino acid (20 μmol per ml gel). Column 1 carried bovine serum albumin treated with glutaraldehyde, column 2 carried albumin treated with glutaraldehyde in the presence of glutamate, and column 3 consisted of portions of agarose particles coupled with the individual carrier proteins and treated with glutaraldehyde. The serial column was eluted with Tris buffer (0.1 M *p*H 7.4) containing NaCl (0.3 M). Glycine buffer (0.1 M *p*H 2.3 with 0.3 M NaCl) or propionic acid (2 M) was then used to regenerate the column. Columns 1 and 2 were essential for specificity, column 3 did not change the specificity of staining of test conjugates or tissue, but slightly reduced the background. Absorption of the purified serum with mycobacteria from the adjuvant did not change the staining of test conjugates or tissue. The specific antibodies could be completely removed by passage through a microcolumn of agarose particles carrying glycine fixed to ovalbumin by glutaraldehyde, or preformed complexes of glycine and glutaraldehyde (see below) attached to lysine-Sepharose (Pharmacia). CNS of *Xenopus* embryos (fixed in 5% glutaraldehyde diluted from 25% in 0.1 M sodium phosphate buffer *p*H 7.4 (NaP_i)) and test filters[6] were incubated together in the purified serum (dilution 1:90–1:400, 3–6 days, 4–6 °C) with 0.5% Triton X-100 and further processed essentially as described previously[6]. Penetration of reactants was enhanced by soaking the CNS in sucrose (30% in NaP_i), freezing in liquid N_2 and thawing at room temperature before incubation with the antisera. The test conjugates spotted on the filter semicircles were prepared by mixing 4.5 mg tissue protein per ml in NaP_i with 20 mM amino acid and 50 mM glutaraldehyde for 1 h, and dialysing. Specificity was further demonstrated by adding glutaraldehyde complexes of various amino acids to the diluted serum. The complexes were prepared by mixing amino acid (20 μmol) with glutaraldehyde (40 μmol, that is, optimal stoichiometry[28], total volume 116 μl) for 1 h at room temperature and adding ethanolamine HCl (1 M 384 μl), all in NaP_i (see also ref. 31).

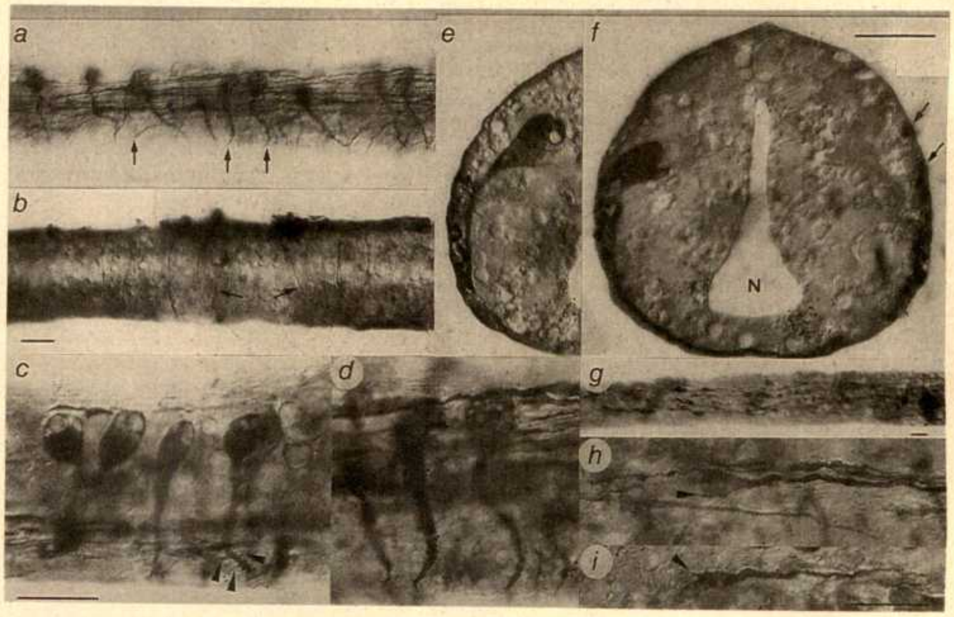

Fig. 2 Characteristic anatomical features of the commissural interneurones of *Xenopus* embryo spinal cord (see also Fig. 3) revealed by specific staining with the glycine antiserum (see Fig. 1 legend). *a*, Lateral view of a slightly rotated spinal cord showing unipolar somata with axons (arrows) crossing ventrally under the neurocoel. *b*, Ventral view of the spinal cord showing the crossing axons (arrows). *c*, *d*, High-power lateral view of stained cells with dendrites (arrowheads) coming out of the fat proximal process. *e*, *f*, Transverse sections (6 μm) of immunostained spinal cords osmicated and embedded in Araldite showing two unipolar somata with axons crossing ventrally under the neurocoel (N). The marginal zones clearly contain transversely cut stained axons (arrows). *g*–*i*, Stained axons and growth cones in the lateral axon tracts. Arrowheads show short micropodia emanating from growth cones. The large unstained inclusions are yolk platelets which are present in all the embryonic cells. Interference contrast optics; all from whole-mounts except *e*, *f*. Scale bars, 20 μm.

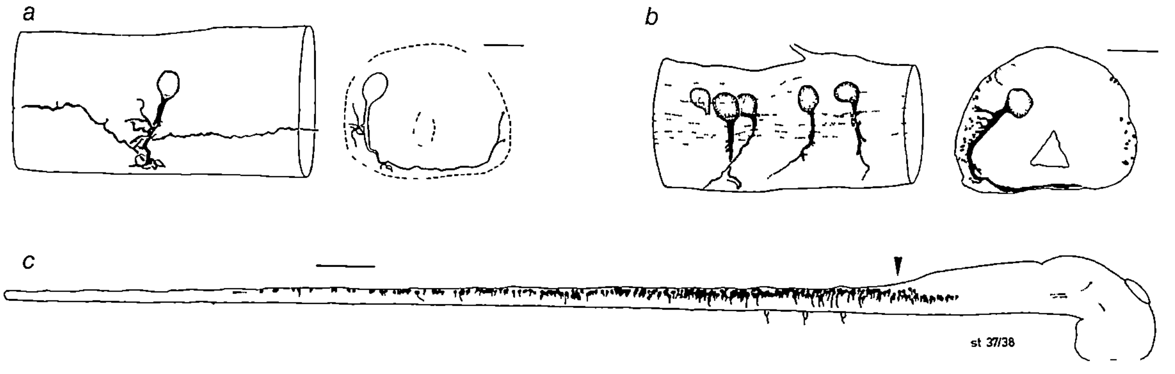

Fig 3 Camera lucida drawings of commissural interneurones from *Xenopus* embryo spinal cord *a*, Commissural interneurone filled with horseradish peroxidase from the intracellular recording micropipette in a stage 37/38 embryo Left, lateral view, right, reconstruction of the transverse section view of these cells (based on micrometer readings in the side view) showing dendrites and axon passing under cord before forming ascending and descending branches (redrawn from ref 10) *b*, Neurones stained with the glycine antiserum showing similarity with *a* Left, drawing of trunk spinal cord from whole-mount at stage 33/34 (lateral view) Four of the stained cells have a unipolar soma with their main ventral process with short dendrites, and an axon which runs ventrally to cross to the other side Dotted lines show stained axons Right, 6-μm transverse plastic section of stage 37/38 rostral trunk cord Stained axons are present throughout the marginal zone on each side One faint and one clear soma are present on the left side The latter has a large ventral process giving off dendrites into marginal zone and continuing ventrally to run under neurocoel to the opposite side *c*, Selective distribution of glycine-positive neurones along the neuraxis in a stage 37/38 embryo Arrowhead shows border between hindbrain and spinal cord All neurones (299) on one side are shown Scale bars, *a*, *b*, 25 μm, *c*, 200 μm

To investigate whether these neurones contain an elevated glycine concentration, we processed the embryo CNS with the glycine antibodies This gave specific staining of a population of cells with the three defining features of commissural interneurones outlined above (Figs 2*a*–*f*, 3*b*) At stage 37/38[23] there were about 300 cells per side extending from the mid-hindbrain to the caudal spinal cord (Fig 3*c*) Comparison with results from retrograde HRP filling indicated that the glycine antiserum had stained the whole population of commissural interneurones The most caudal somata were often paler than the rest, suggesting that cells in this region were still differentiating A few of the stained somata lay close to the cord surface in a dorsolateral position (Fig 3*b*) These cells may either be commissural interneurones with slightly different anatomy, or members of the other class of spinal interneurone with crossed axons, the dorsolateral commissural interneurones[9] Staining of ventral commissural and longitudinal axons was darker than that in somata Some axons bifurcated before reaching the other side Ascending axons reached the rostral hindbrain while a few extended into the midbrain or even the forebrain Descending axons reached to within 600 μm of the caudal end of the spinal cord at stage 37/38 Many axons terminated in large, stained growth cones (Fig 2*g*–*i*) No other groups of somata were stained

An antiserum specific for GABA[6] stained spinal interneurones with ascending axons and one class of possible receptor cells, the ciliated ependymal cell (Fig 1*h*)[9,25] However, it did not stain any commissural interneurones or ventral commissural axons in the spinal cord Antisera specific for taurine[26] or β-alanine (S Davanger, A Bruun, B Ehinger, J Laake, L Orensanz, O P O & J S -M , in preparation) produced no staining of cells or fibres in the *Xenopus* embryo spinal cord Our immunocytochemical data together with the pharmacological and physiological evidence thus suggest that glycine rather than another inhibitory amino acid is the transmitter of the commissural interneurones

We thank A T Bore, T Eliassen, I Fridstrøm, G F Lothe, K Stentoft, L J Teagle and J Line Vaaland for assistance This work was supported by the Norwegian Research Council for Science and the Humanities, the SERC, the Company of Biologists, the Norwegian Council on Cardiovascular Disease and the NFtKB

Note added in proof Campistron *et al*[29] have recently reported on an antiserum to glutaraldehyde-fixed glycine (reacted with $NaBH_4$) and used it to stain neurones in rat brain and spinal cord With a few exceptions, their results are similar to those obtained in rat with our antiserum[30]

T-cell epitope of the autoantigen myelin basic protein that induces encephalomyelitis

Scott S. Zamvil*, Dennis J. Mitchell*, Anne C. Moore*, Kumiko Kitamura*, Lawrence Steinman* & Jonathan B. Rothbard†‡

† The Imperial Cancer Research Fund, P O Box 123, Lincoln's Inn Fields, London WC2A 3PX, UK

Chronic relapsing paralysis and demyelination within the central nervous system (CNS), features associated with the human disease multiple sclerosis (MS)[1-4], develop in mice after injection of murine T-cell clones specific for the autoantigen myelin basic protein (MBP)[5,6]. We examined the fine specificity of three independently derived encephalitogenic T-cell clones using synthetic polypeptides derived from portions of the N-terminal sequence of MBP. These clones appear functionally identical; they all respond to an epitope in the N-terminal nine amino acid residues in association with the same class II (I-A) molecules of the major histocompatibility complex (MHC). Both the N-terminal acetyl moiety and the first residue (Ala) are necessary for recognition. Only N-terminal MBP peptides recognized by these clones were found to cause encephalomyelitis (EAE) *in vivo*. These results show that the N-terminal MBP-specific T lymphocytes that mediate autoimmune encephalomyelitis are a small population with a limited repertoire; they all recognise the same combination of MHC and target.

EAE is a model for autoimmune diseases mediated by class II restricted T lymphocytes[5-10] Immunization with intact MBP or fragments of MBP causes EAE in susceptible mouse strains[10-12] However, not all such fragments are encephalitogenic Only the N-terminal 37 amino-acid MBP fragment causes EAE in PL/J (H-2^u) and (PL/J × SJL/J (H-2^s))F_1 ((PLSJ)F_1) mice[11,12] Encephalitogenic T-cell clones with the $L3T4^+$, $Lyt2^-$ phenotype have been isolated from both these strains following immunization with either intact rat or bovine MBP[5,6] Clones PJR-25 and F1-12 were isolated from homozygous PL/J and (PLSJ)F_1 mice, respectively, after immunization with intact rat MBP Encephalitogenic clone PJB-20 was isolated from homozygous PL/J mice after immunization with intact bovine MBP These clones respond to a determinant shared with mouse (self) MBP within the encephalitogenic N-terminal MBP fragment in association with I-A^u($A_\alpha{}^u A_\beta{}^u$) class II molecules Class II-restricted T lymphocytes recognize discrete, contiguous sequences within proteins, sometimes fewer than ten residues[13] in length via their antigen-specific cell surface receptors[14,15] To investigate the pathogenesis of this autoimmune disease further, we examined whether these encephalitogenic T lymphocytes all respond to a common epitope, or have distinct N-terminal MBP specificities

Separate forms of intact MBP with different N-terminal sequences were tested for their ability to stimulate proliferation of encephalitogenic T-cell clones Bovine MBP was found to be less stimulatory than mouse or rat MBP at the same concentration (results not shown) Since the N-terminal 37 amino-acids of bovine MBP differ from mouse MBP only at residues 2 and 17 (see Fig 1)[16], we predicted that the epitope(s) recognized by these T-cell clones would include one of these two residues The overlapping peptides pR(rat)1-16 and pR5-20 were made and tested for their ability to stimulate proliferation of these clones The epitope recognized by all three clones is found in the N-terminal 16 residues, peptide pR1-16 is as effective as intact MBP (Fig 2*a*) whereas pR5-16 and pR5-20 do not stimulate proliferative responses These clones also respond to peptides pR1-9 and pR1-11 Since pR1-11 and pR1-16 are equipotent, residues 12-16 do not contribute significantly to the epitope recognized by these T-cell clones

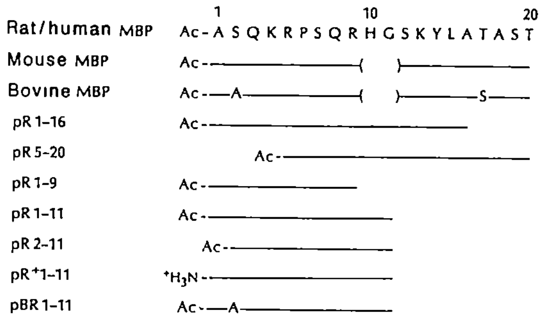

Fig 1 Amino-acid sequences of MBP from different species, and synthetic MBP peptides The sequences of intact rat, human, mouse, and bovine MBP have been published previously[16] Peptides corresponding to the sequences of rat (R) and bovine (B) MBP were synthesized as described previously[29,30] by solid phase techniques on a Beckman Model 990 B peptide synthesizer, using commercially available amino acid polystyrene resins and t-Boc-protected amino acids from Peninsula Laboratories The protecting groups used were o-benzyl esters for Thr and Ser, tosyl for His, orthochlorobenzyloxycarbonyl for Lys, and 2,6-dichlorobenzyl for Tyr Couplings were performed using a 2 5 molar excess of t-Boc amino acid and dichlorohexylcarbodiimide (DCC) over the number of milliequivalents of mino acid on the resin All couplings were >99% complete, as determined by reaction with ninhydrin The peptides were deprotected and removed from the resin simultaneously by treatment with anhydrous hydrogen fluoride in the presence of anisole, dimethylsulphide, and indole, then separated from organic side products by extraction with ether and isolated from the resin by extraction with 5% acetic acid and subsequent lyophilization Purity was determined by high pressure liquid phase column (Merck) and amino acid analysis The peptides used in these experiments were not further purified as they all contained >90% of the desired peptide

Acetylation of the first residue (NAc-Ala_1) is essential for recognition When the acetyl group is removed, revealing a positively charged amino terminus (pR^+1-11, Fig 1), proliferative activity is eliminated (Fig 2*b*) The amino-acid Ala_1 is also necessary, since the MBP peptide pR2-11, containing NAc-Ser_2 is not stimulatory even at the highest concentrations tested Bovine MBP, which has an alanine instead of a serine residue at position 2 (see Fig 1), is less encephalitogenic than intact rat or mouse MBP, which both have Ser_2, in homozygous PL/J and (PLSJ)F_1 mice[11] Peptide pBR1-11, which has Ala as the second residue in a rat MBP1-11, sequence (Fig 1) is less effective than pR1-11 and requires higher concentrations to stimulate proliferation Thus, these representative T-cell clones isolated after stimulation with rat MBP or bovine MBP share the same N-terminal specificity We also identified a second T-cell epitope in the encephalitogenic N-terminal fragment of rat MBP T-cell clones that are restricted to $A\alpha^s A\beta^u$ class II molecules isolated from (PLSJ)F_1 mice recognize rat but not mouse (self) MBP, and are not encephalitogenic The epitope recognized by these T-cell clones is found in pR9-16 (Fig 3) Thus there are two distinct epitopes in the N-terminal 16 residues of MBP

MBP peptide fragments have been shown to cause acute encephalomyelitis in other animal models[17-22] However, peptides as small as those described in this report have not previously been shown to cause EAE in mice Peptides pR1-9, pR1-11, and pR1-16, all of which are recognized *in vitro* by encephalitogenic T cell clones, cause EAE in (PLSJ)F_1 mice when given in adjuvant, without carrier protein (Table 1) Histo-

MBP peptides were tested for their ability to cause EAE following the protocol described previously[11,12] for induction of EAE in mice with intact MBP. Each peptide was dissolved in phosphate buffered saline (PBS) and emulsified with complete Freund's adjuvant (CFA) in a 1:1 mixture of PBS:CFA containing 4 mg ml^{-1} H37Ra (Difco). Recipient (PLSJ)F_1 female mice (Jackson Laboratories, Maine), aged 12–20 weeks, were injected with 0.1 ml emulsion at the base of the tail. On the same day 10^{10} heat killed *Bacillus pertussis* (Michigan Department of Health, Lot 91B) were injected intravenously. Forty-eight hours later 10^{10} *B. pertussis* were injected a second time. Mice were examined daily for signs of EAE by two independent observers. Severity of EAE was graded using a scale previously described[6]: 0, no sign of EAE, 1, decreased tail tone only, 2, mild paraparesis, 3, moderately severe paraparesis, 4, complete paraplegia, 5, moribund. Synthetic peptides pB1-9, pBR1-11, and pR5-20 have also been tested (results not shown). When (PLSJ)F_1 mice are injected with 100 μmoles pB1-9 or pBR1-11, peptides that are recognized by encephalitogenic T cell clones, clinical and histological EAE are observed. Peptide pR5-20 is not encephalitogenic.

logical examination of paralysed mice shows perivascular infiltration of mononuclear cells in the CNS, as observed in EAE caused by immunization with whole MBP[10,11]. In contrast, peptides pR2-11, pR5-16, pR9-16, pR11-27 and pR20-37, which do not stimulate encephalitogenic T-cell clones to proliferate *in vitro*, do not cause clinical or histological signs of EAE in (PLSJ)F_1 mice (Table 1).

T-cell clones recognize peptide sequences in association with a particular class II MHC product. Encephalitogenic T-cell clones isolated after immunization with intact MBP recognize pR1-11 in association with I-A^u class II molecules (Fig. 2*b*). It is possible that encephalitogenic (PLSJ)F_1 T lymphocytes may recognize this epitope in association with other class II molecules. However, immunization with pR1-11 causes EAE in H-2^u strains (PLJ 7/10 mice paralysed and B10.PL 10/10 paralysed), but not H-2^s strains (SJL/J 0/10 paralysed and B10.S 0/10 paralysed), and lymphocytes primed *in vivo* with pR1-11 are inhibited from responding *in vitro* to either pR1-11 or intact MBP by monoclonal antibodies specific for I-A, but not I-E molecules (results not shown). Thus, the encephalitogenic responses to intact MBP and N-terminal MBP peptides in PL/J and (PLSJ)F_1 mice are restricted to I-A^u class II molecules.

We have thus identified the epitope recognized by T-cell clones which mediates autoimmune encephalomyelitis. These independently-derived T-cell clones appear to have functionally identical peptide specificity and class II restriction. Further, the induction of autoimmune encephalomyelitis by *in vivo* administration of N-terminal MBP peptides correlates with T cell recognition *in vitro*, of all N-terminal MBP peptides tested, only those peptides which are recognized by these independently-derived T-cell clones are encephalitogenic. T-cell clones derived after immunization with pBR1-11 or pR1-11 also have the same N-terminal MBP and class II specificity as the clones described here. Clones derived from mice immunized with pBR1-11 respond in a heteroclitic manner, like PJB-20 they respond better to pR1-11 than to pBR1-11, the original immunogen (results not shown). Thus, *in vitro* and *in vivo* results suggest that the encephalitogenic T-cell response to MBP 1-37 is limited to a discrete population of MBP-reactive T cells.

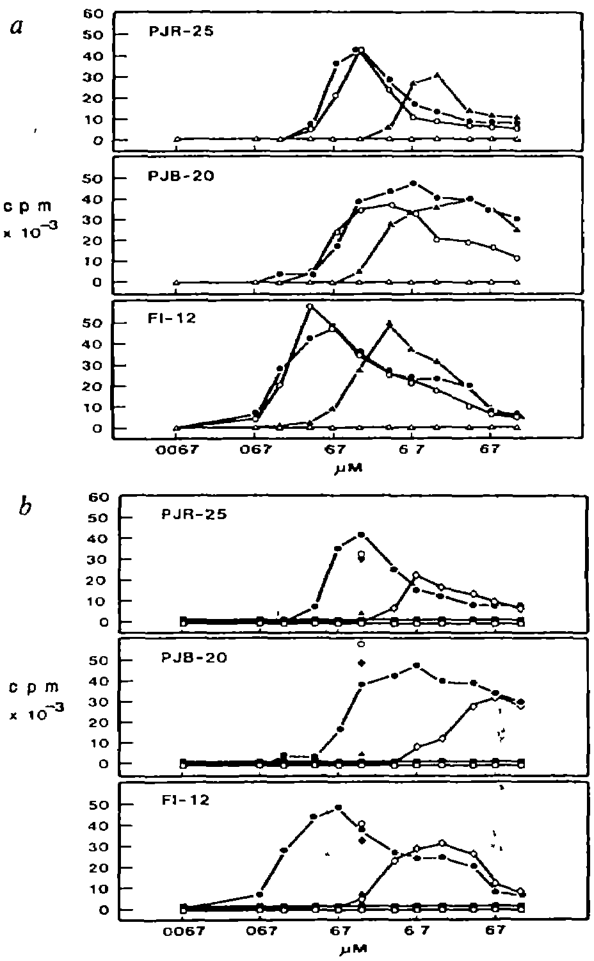

Fig. 2 Recognition of N-terminal MBP peptides by encephalitogenic T cell clones. *a*, Peptides pR1-16 (○), pR1-11 (●), pR1-9 (▲), and pR5-20 (△) were tested for their ability to stimulate encephalitogenic proliferative T cell clones, isolated as described previously[16,31]. To assay for proliferative responses, 10^4 T cells were cultured with 5×10^5 X-irradiated (3,000 rad) PL/J splenic antigen presenting cells (APC) in 0.2 ml culture media in 96 well flat-bottomed microtitre plates (Falcon). Culture medium was RPMI 1640 (Gibco, supplemented with 10% fetal calf serum (Hyclone), 5×10^{-5} M 2-mercaptoethanol, 2 mM glutamine, 100 U ml^{-1} penicillin and 100 μg ml^{-1} streptomycin). Peptides were added to cultures giving the final concentrations indicated. At 48 h each well was pulsed with 1 μCi ^{3}H-thymidine and cells collected 16 h later. The mean c.p.m. for thymidine incorporation was calculated for triplicate cultures. Standard deviations are within 10% of the mean. The same pattern of response to N-terminal peptides is found when these T cell clones are cultured with (PLSJ)F_1 APC. *b*, Peptides pR1-11 (●), pBR1-11 (◇), pR^{+}1-11 (□), and pR2-11 (■) were tested as described above. In a separate assay, the proliferative response to pR1-11 (○) was inhibited with 1 μg per well anti I-A monoclonal antibody 10-2.16 (ref. 32) (▲), but not anti I-E monoclonal antibody 14-4-4[33] (◆). When tested at this concentration, 14-4-4 inhibits T cell clones restricted to I-E molecules[6] (results not shown).

It has recently become possible to examine the genes that encode antigen-specific T-cell receptors (TCR)[23–25] and investigate the relationship between specificity and TCR gene expression. Ovalbumin-specific T-cell clones that recognize the same epitope and share the same class II restriction have been shown to use the same V_α/J_α and V_β/J_β TCR genes[26], T-cell clones that share the same fine specificity for cytochrome C use the same V region genes, but can express different J elements[27]. However examination of TCR genes from clones of different specificities suggests that there may not be a simple correlation

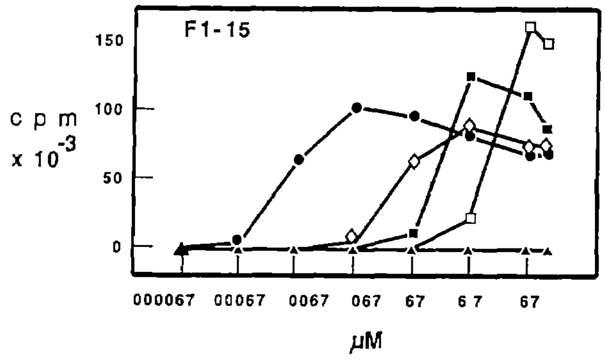

Fig. 3 N-terminal peptides recognized by a representative non-encephalitogenic MBP specific T cell clone Peptides pR1-16 (●), pR5-16 (◇), pR7-16 (■), pR9-16 (□) and pR10-20 (▲), were tested as described (Fig 2, legend) F1-15 T cells were cultured with (PLSJ)F$_1$ splenic APC These N-terminal MBP-specific non-encephalitogenic T cell clones are restricted to $A\alpha^s A\beta^u$ class II molecules N-terminal peptides that are recognized by these non-encephalitogenic T cell clones do not cause EAE (see Table 1)

between V_β expression and T-cell specificity[28] The TCR genes from encephalitogenic T-cell clone PJR-25 are being cloned, and should be useful probes allowing us to examine whether other encephalitogenic clones, which share the same epitope and class II restriction, express the same TCR genes

We have described here the first investigation of the fine specificity of T cell clones mediating an autoimmune disease Two distinct T-cell epitopes in MBP 1-16 have been characterized Examination of the response to MBP peptides, both *in vitro* and *in vivo*, has revealed that only a limited repertoire of N-terminal specific T lymphocytes, expressing a common class II restriction and peptide specificity, mediate induction of EAE These results may provide insights into the immunogenetic mechanisms of other autoimmune diseases In cases where only a limited repertoire of T lymphocytes mediate autoimmune pathogenesis, specific forms of therapy might be possible For example measures which selectively inactivate or eliminate only autoaggressive T cells bearing the N-terminal MBP specificity may be beneficial in the treatment of autoimmune encephalomyelitis

We thank Teri Montgomery for her valuable assistance and Professors Hans Acha-Orbea, Mark Davis, Robert Fritz, Garry Fathman, Phillipa Marrack, Hugh McDevitt, Patricia Nelson, Tim Vollmer and Matthew Waldor for helpful discussions I S is supported by NIH grants NS00571, AI22462 and NS18235, the Rosenthal Foundation, the Fausel Foundation and the Swim Foundation
